Occupational dermatitis must be differentiated from such diseases as seborrhoeic dermatitis, fungus infections, lichen planus, impetigo contagiosa, pityriasis rosea, erythema multiforme, drug eruptions, neuro dermatitis and dermatitis due to contact with irritants met with outside of the place of occupation. The industrial physician or the general practitioner may at times be in doubt about the diagnosis of these conditions in a worker exposed to an occupational skin hazard, especially if he does not strip the patient and examine the entire surface of the skin, but to the dermatologist the characteristic location or appearance of seborrhoeic dermatitis, lichen planus, impetigo contagiosa and neuro dermatitis and the generalized eruptions of pityriasis rosea, erythema multiforme and drugs offer no great problem in differential diagnosis from occupational dermatitis. It is true that the presence of these conditions does not rule out the fact that an industrial dermatitis may also be present. In fact, the presence of certain of these skin diseases often predisposes a worker to an industrial dermatitis. The greatest difficulty in differential diagnosis is presented by dermatitis due to contact with substances met with outside of the place of occupation. In these cases the lesions are similar in appearance and site, and only the most careful consideration of all the facts can lead to a correct etiology. It is here

that the patch test is of greatest value.

The patch test is based on the theory that if a dermatitis is caused by hypersensitivity to a certain substance, then if that substance is applied to an area of unaffected skin of the susceptible individual and left on for a period of time, it will cause an inflammation at the spot where it touches the skin. In doing patch tests, it is important to know what concentrations of certain chemicals can come in contact with the normal skin for a stated period of time without causing an inflammation or reaction. It is also important that no general irritants, such as strong acids or alkalis are used in the patch test, because obviously they will burn any skin. The portion of the body on which a patch test is to be performed is also of importance because it has been found that the different portions may vary in sensitivity to certain chemicals. For instance, the tough horny skin on the hand is less susceptible to irritants than the more tender skin on the inner surface of the forearm. Then again, it has been found that the portion of the skin which is affected is more sensitive than other portions of the skin. For this reason, patch tests performed on uninflamed skin adjacent to the eruption are more likely to give positive reactions than when performed on more distant areas. It may even be necessary to wait until the eruption heals so that patch tests may be performed on the same portion of the skin which was affected.

If the worker is handling known irritants and his fellow workers are also affected, the cause is obvious and the patch test is unnecessary, but if he is the only one of the group who is affected, then he should be patched with the materials with which he comes in contact in the course of his occupation. If he is patched with only one substance, then a control patch should

be placed on him. If he is patched with more than one substance, then any negative reaction from one of these substances serves as a control. It is also desirable to use as a control one of the workers who has no dermatitis.

In patching with solids, best results are obtained by moistening them, preferably with perspiration from the patient which can be obtained from the axilla. Sometimes it may be necessary in order to obtain a reaction from a patch test, to use perspirations of different hydrogen ion concentrations (Ref., Schwartz, Louis. Sensitivity to External Irritants in Industry, *New York State Journal of Medicine*, 36, 24) (Dec. 15), 1936. The results of patch tests must be correlated with the worker's particular occupation, the history of the dermatitis, the site and morphology of the lesion, in order to arrive at a correct etiology. Patch tests are only a link in the chain of evidence on which a diagnosis of industrial dermatitis is made. A positive reaction only shows that the portion of the skin on which the patch was applied was at that time sensitive to the substance with which it was patched. In order to state that this substance was the cause of the occupational dermatitis, we must be sure that the patient was exposed to the substance in the course of his work and presuppose that the patient's skin was also sensitive at the time of industrial exposure.

When negative results are obtained from patch tests with the materials met with in the course of the patient's occupation, we must not hastily conclude that the dermatitis is not of industrial origin, because the skin area over which the patch was placed may not be hypersensitive, while the area covered by the eruption may be hypersensitive. Or, if the eruption has disappeared, the patient may no longer

be sensitive when the patch test is performed but may have been sensitive at the time he had the eruption and when he was industrially exposed. Or, a negative patch test reaction may be due to the fact that the patch test never accurately reproduces actual working conditions, such as friction, maceration, heat, cold, and sunlight, which may be additional factors adding to the irritating effect of the substance to which the patient is exposed. Or, it may be that the concentration of the chemicals applied as a patch test may not be as great as they actually were during industrial exposure. Or, finally, the actual industrial irritant may not have been discovered and applied as a patch test. When negative reactions are obtained from patch tests with substances encountered in the work room and the dermatitis which the worker has resembles a contact dermatitis, an effort must be made to perform patch tests with materials met with in the patient's home which may be the causes of dermatitis. For instance, certain plants, or perhaps paints or even new furniture. Tests of this kind will in some cases show that the patient is sensitive to materials met with outside of industry and not sensitive to the materials which he meets in his place of employment.

The technic of performing patch tests is important in obtaining and evaluating results. When patch testing for hypersensitivity to general irritants, such dilutions must be used in the tests as are known not to irritate the normal skin (Ref., Schwartz, Louis: Sensitivity to External Irritants in Industry, *New York State Journal of Medicine*, 36, 24 (Dec. 15), 1936. The insulating material inserted between the chemical and the adhesive plaster should be a non-irritant substance, such as unvarnished cellulose or, better still, a thin sheet of mica may be used. The resin on waterproof cellophane itself

may be an irritant as may be some of the compounds in dental rubber. The adhesive plaster used to hold the patch in place often itself causes an erythema of the skin (Ref., Schwartz, Louis and Peck, Samuel M. The Irritants in Adhesive Plaster, *Public Health Reports*, 50, 24 (June 14), 1935.

At the time the patches are removed there may be no reaction present, but some time later—a few hours to a few days—a delayed reaction may develop at the site of the patch. There is some dispute as to the significance of delayed reactions. Some hold that the skin was sensitized by the patch test but I think that in our present state of knowledge we should regard delayed reactions as denoting hypersensitivity just as undelayed reactions do. Patch tests properly performed and evaluated can be of great help in the diagnosis of industrial dermatitis, but if improperly performed and evaluated, they may lead to confusing and unjust conclusions.

Fungus infections also offer a problem in differential diagnosis from industrial dermatitis. A large percentage of workers are affected with mycotic infections in some form or other. Epidermophytosis, trichophytosis, tinea cruris and tinea versicolor are common skin diseases. Allergic reactions in the form of dermatoses on distant parts of the body resulting from these fungus infections are recognized by allergists and dermatologists. These allergic reactions or phytids may be confused with industrial dermatitis. If the phytids or the mycotic infections appear on portions of the body not exposed to industrial irritants, they are not so apt to cause doubts in diagnosis, but they often appear on the hands and here they are apt to cause trouble in diagnosis. The various tests with fungus extracts, such as trichophytin, are of little value in making a differential diagnosis because nearly every

one has or has had a fungus infection, and positive reactions are the rule. They are of more value when the tests are negative, because then they tend to show that the present eruption is not of fungus origin, although even here it is not absolute proof, because among other reasons the causative fungus may not be the one from which the testing extract is made. Then again, the fact that a worker has a fungus infection does not preclude the fact that he may also have an industrial dermatitis. In fact, it is held by some dermatologists that the presence of a fungus infection predisposes to hypersensitivity to other external irritants. Patch testing may offer some help but here again the industrial exposure, the history of the eruption, the site of the lesions and their morphology must all be carefully considered before a diagnosis is made.

Chronic eczemas, more or less generalized and of long standing offer very difficult problems in etiology, especially when they are complicated by secondary infections. Patch tests are of little value in most of these cases, because polysensitivity is usually present. It is impossible to determine whether the dermatitis and polysensitivity was caused by industrial exposure or whether the sensitivity was present before the industrial exposure or whether the dermatitis and sensitivity were caused by exposure to substances encountered outside of the work-room.

Cases sometimes appear before compensation boards claiming compensation for disability due to a dermatitis which the worker claims to have suf-

fered as a result of his occupation, but which at the time the case is being heard, has disappeared. In these cases, it is also difficult to determine the causative factor. If patch tests done at this time are positive, they are of great help, but if negative, they are not, because the patient may have developed an immunity by his recovery.

From these facts it can be seen that there is no one characteristic symptom on which a diagnosis of an industrial dermatitis can be made. The worker's occupation, the history of his skin eruption, its site and morphology and evaluation of the patch tests must all be taken into consideration by a dermatologist familiar with the substances and the processes of the worker's occupation before we can hope to make a true diagnosis as to the etiology of a dermatitis in a worker exposed to an occupational skin hazard.

Interrelationship of Health and Welfare Records and Statistics*

EWAN CLAGUE, PH.D.

*Director, Bureau of Research and Statistics, Social Security Board,
Washington, D. C.*

IN the past, records of births and deaths have been of considerable importance to welfare administrators, but the passage of the Social Security Act has made these records a matter of vital and fundamental importance both for direct administrative purposes and for public information.

These records are now being used to some extent by the state welfare departments in the administration of public welfare assistance. This use will undoubtedly continue to grow. However, the development of the federal program of old age insurance will produce a very great demand for health records. There are now over 37 million account numbers assigned by the Bureau of Old Age Insurance of the Social Security Board, and this number will steadily increase over the next few years.

We have already experienced the need for birth certificates, particularly for the determination of age. In view of the inadequate birth registrations in the past, there has been considerable administrative difficulty in determining age. From now on there is likely to be on the part of the public more insistent pressure for full registration

in order that age determinations for the future may be made properly. However, since the birth at the present time and the award of the benefit 65 years later are rather remotely connected in people's minds, this will probably not be enough to insure complete registration.

The death certificate is important for the payment of benefits now—not the monthly benefits which are paid to an individual during his lifetime, but the lump sum payments which are made at the time of death to the estate of the beneficiaries.

At present, the Bureau of Old Age Insurance is using three alternative forms: (a) the death certificate; (b) a statement by the attending physician; and (c) a statement by the undertaker. Very serious consideration was given to the proposal of requiring the use of the death certificate exclusively, but it was felt that death registrations were not sufficiently advanced at the present time to warrant it. Furthermore, the claims at present are rather small and the incentive to fraud is not very great. As time goes on, and the claims become much larger, it will become more necessary for the Social Security Board to insist upon proper certification of death. The question is, could we go to the exclusive use of the death certificate?

The desirability of such a method

* Abstract of a paper read at a Joint Session of the American Association of State Registration Executives and the Vital Statistics Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

seems to be without question. The death certificate contains a vast amount of information which would be exceedingly useful for the administration of old age insurance.

On the other hand there would undoubtedly be certain serious administrative problems involved, particularly (a) cost, and (b) the technic of using the certificate.

Necessarily the claimant must be protected from much expense in filing the claim. This is not so necessary where the claim is large but there is no way of knowing in advance how large a claim might be. Therefore, it might be necessary either for the state agency to bear this expense as a service to the federal government for old age insurance purposes, or for the Social Security Board to bear the cost as an administrative expense. There is also the possibility that such expenses might be charged back by the board against

the payments finally made when the claim is adjudicated.

The technic of using these death certificates is somewhat complicated, especially in view of the fact that corrections are sometimes made long after the original filing of the certificate. This means that statistical information obtained from the certificates must be carefully checked before being used. There are some further administrative problems in comparing the Social Security Board records with the certificates. In general, however, there are no insuperable difficulties to such an arrangement, provided there were a definite decision to make out of the death certificate for claims purposes.

It seems likely that in the longer future the Social Security Board will want to give careful attention to the possibility of requiring the death certificate exclusively as a prerequisite for the presentation of a claim.

Lung Findings in Foundry Workers

A Four Year Survey*

O. A. SANDER, M.D.

Industrial Physician, Milwaukee, Wis.

NUMEROUS foundry operations have for many years been producing chronic lung changes in those exposed to their dust, but this fact did not become generally appreciated until about 10 years ago. Many of the largest foundries were still permitting their sandblasters to work without positive pressure helmets as late as 1930, even though the hazard had been described as early as 1860.¹ Many sandstone grinding wheels were not replaced by artificial abrasive wheels until the past 5 years, even though the early literature is full of the dangers of the use of the natural stone wheel.

That the foundry industry was so tardy in realizing its dust hazard is due to a number of factors, chief of these being the great increase in concentration of the dust generated during the industrial boom from 1915 to 1925. During those years machine methods were replacing the old hand methods with the resulting excessive exposures. Most cases of silicosis developed during this speed-up era did not begin to manifest themselves until after 1925, earlier cases having been so relatively infrequent that they were not suspected as occupational in many instances.

So little was the foundry industry

concerned with these earlier isolated cases that a survey to determine the extent of the hazard was not attempted anywhere until 1931. By that time the studies in numerous other industries had become quite extensive and the statistical data from the South African Mines and the Barre Granite Quarries were being quoted generally. The fear was spreading that the foundry silicosis hazard might be equally great.

Early in 1931 the Wisconsin Manufacturers' Association requested the Metropolitan Life Insurance Co. to make a health survey of representative foundries in and around Milwaukee. Only the longest and the most dangerously exposed employees in each of 41 plants were selected for roentgen examinations. Sixty-seven of the 215 studied (31 per cent) were diagnosed as having silicosis but advanced cases were not found.² This indicated the presence of a definite hazard, but justified the conclusion that it was neither as severe nor as extensive as it had been shown to be in other industries. The report recommended the selection of workers in foundries by preemployment examinations and chest X-ray, along with periodic examinations of those dangerously exposed.

As a result of these recommendations, the survey reported here was begun in December 1932. Details of the procedure have been described in previous reports,^{3,4} the present one,

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

TABLE I
Incidence of Silicosis

<i>Roentgen Classification</i>	<i>Non-dusty Group (Modal Age 23)</i>		<i>Foundry Group (Modal Age 45)</i>		
	<i>Number</i>	<i>Per cent</i>	<i>Number</i>	<i>Per cent</i>	
1. Lung markings normal	2,018	83	893	22	
2. Slight truncal exaggeration	392	16	1,885	47	} 71%
3. Marked truncal exaggeration	34	1	978	24	
4. First degree nodulation (nodules less than 2 mm.)	0	0	255	6.3	} 7% silicosis
5. Second degree nodulation (nodules 2 to 4 mm.)	0	0	22		
6. Third degree nodulation (nodules over 4 mm.)	0	0	2	0.7	
	2,444		4,035		

however, being the first attempt at a statistical analysis of the findings. Well over 15,000 individuals from numerous industries have been studied, of which close to 10,000 are foundry workers. Because of lack of time for tabulation, only slightly more than one-third of the cases studied could be made part of this report. It does include, however, practically all cases that have been seen over a 4 year interval.

The classification of X-ray appearances of the lungs used is that suggested by a special committee of authorities on this subject in 1935.⁷ While it admittedly is most difficult in borderline cases to state with definiteness that this case is silicotic and that one is not, our cases were not classified as silicotic unless the nodulation was quite definite and well distributed in both lungs. Considerable exaggeration of the linear markings with and without beading along the bronchial trunks was considered within the limits of the healthy lung picture.

INCIDENCE OF PROMINENT TRUNK SHADOWS

As a control, we have been fortunate to have had available for study a

rather large group of machine shop employees and others who had never been exposed to industrial dust. In Table I* the X-ray appearances in this non-dusty group are compared with those whose dust exposure has been entirely in foundries. While none of the 2,444 who had never been exposed to industrial dust had any nodular shadows, 392 (or 16 per cent) showed slight exaggeration of the bronchial and linear markings, and 34 (or slightly over 1 per cent) had marked exaggeration of these trunk shadows. In many cases these were believed to be secondary to a chronic nasal and sinus infection and in others no apparent cause could be found.

In the foundry group of 4,035, on the other hand, 1,885 (or 47 per cent) had slight exaggeration of the trunk shadows, and in 978 (or 24 per cent more), they were markedly exaggerated, with and without beading. Before further comparisons between the two groups are made, however, it must be noted that the non-dusty group is very much younger, slightly over 50 per cent

* It should be noted that all figures given in this report are direct tabulations and have not been biometrically corrected for all variables.

being less than 25 years of age. In the foundry group slightly more than 50 per cent are over 40 years of age. With comparable age groups, therefore, a somewhat higher percentage with linear exaggeration might be expected in the non-dusty group. This could never approach the 71 per cent of all foundry workers with exaggerated trunk markings, however, and furnishes rather conclusive evidence that at least 50 per cent of all foundry workers have a definite peritruncal fibrosis due to their previous dust exposure. In spite of this evidence, one still would hesitate to make a diagnosis of pre-silicotic fibrosis from the X-ray alone in individual cases, even when definite beading along the trunk shadows is also present.

INCIDENCE OF SILICOSIS

Our 7 per cent with definite silicotic nodulation, which includes those with infection, is somewhat lower than the 11.4 per cent reported by Pope & Zacks⁶ and higher than that recorded by Kelley and Hall.⁷ It very closely approximates the 9.1 per cent reported by Osmond.⁸ Such over-all percentages, however, mean very little because of the numerous variables, and scarcely are worth recording. For instance, one of our larger steel foundries had an incidence of 25 per

cent definite silicosis cases, whereas the average for all our steel foundries was 13 per cent, our malleable foundries 8 per cent, and that for the gray iron workers 2 per cent.

The reasons for these rather marked differences in the silicosis hazard in the various types of foundries are many, but the chief ones seem to be these: (1) Usually larger castings in steel, requiring more sand chipping by hand with pneumatic hammers; (2) larger castings more difficult to sandblast without throwing excessive dust into general atmosphere; (3) shaking out larger castings much dustier, etc.

INCIDENCE OF TUBERCULOSIS

For comparative purposes, we have divided our foundry men into two main groups: those without nodulation, the non-silicotics, and those with nodulation, the silicotics. In Table II these two groups are compared with the non-dusty group in the incidence of complicating tuberculosis. We have not classified a shadow as "healed" unless it appeared well calcified. Into the "indeterminate" classification we have thrown all shadows that seemed tuberculous which were neither well calcified nor definitely active. For "definitely active" one of the following must have been positive: (1) medium moist rales

TABLE II
Incidence of Tuberculosis

<i>Roentgen Classification</i>	<i>Non dusty Group (Modal Age 23)</i>		<i>Non-silicotic Foundrymen (Modal Age 42)</i>		<i>Silicotic Foundrymen (Modal Age 48)</i>	
	<i>No.</i>	<i>Per cent</i>	<i>No.</i>	<i>Per cent</i>	<i>No.</i>	<i>Per cent</i>
1. No infection	2,393	98	3,552	95	181	65
2. Old healed adult tuberculosis	25	1	116	3	37	13
3. Indeterminate tuberculosis	21	1	73	2	52	19
4. Active tuberculosis	3	0.1	11	0.3	8	3
5. Healed miliary calcifications	2	0.1	5	0.1	0	0
	2,444		3,756		279	

Active tuberculosis all foundrymen: 19 cases (0.47 per cent or 470 per 100,000)

after cough over lung lesion, (2) sputum positive for tubercle bacilli, (3) rapid blood sedimentation, (4) extension of infection shadows on serial films.

In making the comparisons, the differences in the average ages of the three groups must be considered. The figures for the non-dusty and non-silicotic workers approximately represent the expected incidence for their respective age groups in the general population. The non-silicotic foundry group is of special interest in suggesting an answer to a perplexing question which has received few definite answers; namely, "How much does dust exposure *per se* affect the incidence of tuberculosis in lungs as yet not silicotic?" For foundry dust exposure, at least, the tuberculosis rate seems to be no higher among the non-silicotics than in the population as a whole.

For the entire foundry group, including the silicotics, we have found a total of 19 active tuberculosis cases, or an incidence of 0.47 per cent (470 per 100,000). With an expected 300 to 350 per 100,000 incidence in our community as a whole, the foundry rate is about 50 per cent higher than that of the general population. This approximates the estimate reported by Pope and Zacks⁶ in their foundry studies.

Again, such an over-all rate means very little when one considers the extremes. For instance, one of our steel foundries with 175 employees had 6 active cases (3,400 per 100,000), while another equally large foundry showed no active cases. An old active and open chronic fibroid case which was discovered in the former plant may have been the source of infection of several of the other cases, if not all of them.

Also such case rates frequently are criticised because they represent a cross-section of only those employees who

are at work at the time of the survey and do not take into account those active cases that had become incapacitated or died before examinations were instituted. It is felt, however, that these unknown cases are in part counterbalanced by the many early active cases which are discovered by survey long before symptoms develop.

NEW INFECTION VERSUS REACTIVATION

When one considers the silicosis group alone, the tuberculosis rate seems to increase tenfold over the non-silicotic group, although this may be slightly exaggerated by the considerable increase in the average age of this group. It nevertheless is high among the foundry silicotics as with all other silicosis. Possible explanations for this constant finding have interested investigators in this field since the earliest studies. In general, the greater the silicosis hazard, the higher the tuberculosis rate. The question always arises, however, as to whether these silico-tuberculosis cases are primarily exogenous infections superimposed on simple silicosis or whether the majority are reactivations of previously acquired tuberculosis. Our serial observations of about 2,000 of the foundry men over a 4 year interval throw some light on this problem. For instance, in the open case in the foundry foreman who seems to have infected 5 fellow employees, not one of these contact cases was a silicotic and 4 were below age 30. Several cases of simple silicosis are known to have been similarly exposed, but did not become infected. This is slightly suggestive that the silicotic lung at least is no more susceptible to exogenous tuberculosis than is the young healthy lung.

Of the 4,035 foundry workers included in this report, 1,982 (49 per cent) have been observed over 4 years. In only 25 of these (or 1.3 per cent) did progressive lung changes of any

significance occur during this 4 year period. These we have listed in Table III by comparing the new infections with those in which the tuberculosis is a reactivation of a previous infection. By "new infection" is meant that the first chest film had indicated uninfected lungs without even healed infection scars, whereas a subsequent film showed shadows which proved to be developing infection. By "reactivation" is meant that at the first examination the tuberculosis was considered definitely inactive or apparently healed, whereas the later examination showed a spreading active lesion.

In comparing the two groups, the following should be noted:

New Infection (12 cases): *Reactivation* (13 cases):

- | | |
|--|--|
| 1. 4 definitely active | 1. 9 definitely active |
| 2. Only 1 of the 4 is silicotic | 2. 8 of the 9 with definite silicosis |
| 3. The 1 silicotic case only slightly active | 3. In all 8 silicotics, tuberculosis very active |
| 4. In 2 non-silicotics, tuberculosis very active | 4. Tuberculosis least active in non-silicotics |
| 5. All tuberculous lesions apical | 5. 2 cases with basal lesions |
| 6. None have died of tuberculosis | 6. 2 have died of tuberculosis |
| 7. Only 2 over 40 years of age | 7. All but 4 over 40 |

These comparisons illustrate the chief characteristics of silico-tuberculosis as it is found in the foundry worker:

1. Acquired infection before age 40 in the majority of cases.
2. Infection becomes chronic and remains so for many years, complete healing being prevented by the increasing silicotic fibrosis, but this same fibrosis preventing spread of the infection.
3. Tuberculous infection becomes so well walled-off by fibrous tissue that activity frequently cannot be detected by any known laboratory procedures. Considerable calcification may be present in such lesions surrounding living tubercle bacilli.
4. Protecting wall may be broken down and activity of infection increase later in life, often with bronchogenic spread of tubercle bacilli.
5. Very few silico-tuberculosis cases are exogenous tuberculosis superimposed on silicosis late in life.

The molder or coremaker over 50 who has only a mild or even moderate silicotic nodulation acquired by exposure to only minimal concentrations of dust over at least 30 years, runs very little risk of ever acquiring a superimposed tuberculosis. This fact is daily being more definitely proved as the period of observation of those with simple silicosis is lengthening.

PROGRESSION OF SILICOSIS

It has been repeatedly stated in most clinical reports so far published that silicosis once acquired will progress indefinitely regardless of whether or not exposure to dust is terminated. This may be true for other industries with more concentrated silica exposures, but for the 1,982 foundry men whom we have observed for 4 years, we have seen no progression of fibrosis in uninfected lungs. None of those with a pre-silicotic picture (marked truncal exaggeration) have acquired sufficient nodulation to class them now as silicotic, nor have any of those with uncomplicated silicosis visibly increased their nodulation in the 4 year interval, in spite of the fact that the majority have continued their regular foundry work.

The only exceptions to this lack of apparent progression were in the infected cases where a number with only truncal exaggeration have become nodular. This change seemed to occur about the same time that the tuberculosis was becoming active and spreading. Further, the nodulations in most cases appeared first around the tuberculous lesions and seemed to spread outward from there. This visible nodulation we believed to represent individual silicotic nodules which were becoming infected.

Because we have not found visual evidences of progressive fibrosis in uninfected lungs, does not justify the conclusion that progression is not occur-

TABLE III
New Infection (12 Cases)

Case No.	Age (1st Exam.)	Interval (Yrs.) (1st to Last Exam.)	Occupation	Years (Total)	Fibrosis	Type of Tuberculosis
2,644	31	4 (out of fdry.)	Molder	3	None	Indefinite apical shadow, not active

ring. The dust hazard is not entirely eliminated in these foundries and may not be for years, although they are believed to be in a state of good control now. That the rate of progression will continue to be extremely slow, however, is suggested by these observations, proof of which will come with repeated examinations of this group. It is most significant, we believe, that no cases with rapid progression have been discovered. The middle aged foundry man with only mild uninfected silicosis can be assured that he will be able to work out a natural life-time in a mildly dusty atmosphere without acquiring advanced or incapacitating lung fibrosis. Moreover, as we have already stated, his chances of acquiring superimposed tuberculosis are very rare after age 40. Consequently these cases of simple

silicosis are being maintained confidently at their regular employment. Constantly improving dust control in these foundries along with elimination of possibilities of contact tuberculosis, justifies this procedure.

SILICOSIS BY OCCUPATIONS

While it is difficult to pigeon-hole many foundry occupations, general trends can be given regarding the dust hazard of each. *Sandblasting* is, of course, the greatest hazard if done without protection. Our incidence of 15 per cent silicosis is low because very few of the pre-air-helmet blasters are still at work. The few we have seen usually have advanced silicosis. Those who have always been protected with the air helmet are showing no progressive changes, several after 8 and 9 years

of such work. Those with healthy lungs are no longer being shifted to other jobs at intervals, as was the former practice.

Sand chipping and grinding of large castings is the most hazardous foundry

SILICOSIS BY LENGTH OF EXPOSURE

When the non-silicotic and the silicotic foundry men are compared according to length of their dust exposure, the results shown in Table IV are obtained:

TABLE IV

<i>Yrs. of Exposure</i>	<i>Total Number</i>	<i>Non-silicotic</i>	<i>Silicotic</i>	<i>Percentage Silicotic</i>
1 to 5	1,174	1,168	6	0.5
6 to 10	812	788	24	3.0
11 to 15	602	573	29	5.0
16 to 20	532	480	52	10.0
21 to 25	365	311	54	15.0
26 to 30	268	211	57	21.0
31 to 35	135	103	32	24.0
36 to 40	80	66	14	17.5
41 to 45	30	24	6	20.0
46 to 50	17	13	4	24.0

occupation today, our incidence being 28 per cent. Unless castings can be blasted or otherwise cleaned before the chipping operation, high concentrations (upward of 50 million) of a dust high in silica content (up to 90 per cent) may be generated.

Molding per se need not be a hazard if practised carefully and if the general atmosphere is not polluted. Our incidence of 10 per cent is slightly high because of the proximity of many molders to formerly leaky and poorly exhausted sandblast booths.

Coremaking and general core-room work should be no silicosis hazard provided the atmosphere is not polluted from the cleaning room. Our incidence was only 1 per cent.

Other occupations lie between the extremes cited regarding their silicosis potentialities. In general it may be stated that in our experience leaky sandblast and tumbling barrel equipment, sand chipping and grinding, and shake-out operations have contributed materially to the total hazard and must be eliminated first as a source of excessive pollution of the foundry atmosphere.

Significant points to be noted are:

1. Six men acquired a visible nodulation with less than 6 years of dust exposure. All 6 had been sandblasters without protection (massive exposure) at some time in the past, but with a varying interval of years since, in which they had no dust exposure. Two of these had had only 2 years of dust exposure each, one 15 years previously.

2. About half of our foundry workers had had not over 10 years of dust exposure.

3. Twenty-five years is about average length of exposure in our group to acquire demonstrable nodular silicosis.

4. In the group that had had from 40 to 50 years of dust exposure, only 22 per cent were definitely silicotic. This does not mean any peculiar resistance on the part of the 78 per cent without silicosis, but merely indicates the negligible dust hazard of many foundry jobs.

HISTORY OF UPPER RESPIRATORY INFECTION AND PNEUMONIA

It has been our practice to question every applicant for employment concerning his past medical history. Specific questions are asked with reference to (1) frequent colds, (2) bronchitis, (3) pleurisy, (4) asthma, (5) pneumonia.

A survey of our records with respect

to the answers given to these questions leads us to the conclusion that this form of inquiry is extremely unreliable and inexact. It is quite certain that the eagerness of the applicant to obtain employment will tend to make him answer all questions pertaining to past illnesses in the negative. Language difficulties also make history-taking very difficult. Nevertheless, we made an attempt in a preliminary survey to compare the incidence of upper respiratory infection and pneumonia as recorded on our history sheets in the non-dusty, non-silicotic, and silicotic groups. These gave almost identical figures for the 3 groups and suggested that the incidence of upper respiratory infection and pneumonia is the same for individuals whether they are silicotic or non-silicotic, or whether they are employed in dusty or non-dusty trades. From all previously published data this is incorrect and a statistical presentation of this material must, therefore, be postponed until a more precise effort can be made to evaluate our data.

HISTORY OF SYMPTOMS

Here, too, considerable difficulty arises in analyzing records for answers obtained concerning various symptoms referable to the chest. There is a general tendency to deny all symptoms, although occasionally one hears of shortness of breath, cough, pain in the chest, and various combinations of these. In some of the latter, no lung pathology is found and other causes for the complaints must be sought.

The literature is already replete with extravagant statements concerning the symptomatology of silicosis. For example, chest pain is mentioned in the literature as a very frequent complaint, whereas we have been surprised to note how infrequently it has been complained of even on direct questioning

of the more advanced cases. We feel, therefore, that an analysis of the symptoms presented by our foundry groups must be deferred until we are in a position to obtain more precise and correct answers and to observe for ourselves the development of symptoms by repeated serial examinations.*

GENERAL DISCUSSION

The silicosis hazard has been known to differ markedly in the several industries in which it is found, due to the numerous variations in the exposure factors. Similarly, in the foundry industry itself, marked differences in the extent of the hazard exist. The resulting varieties of lung changes range all the way from the classical silicosis of the unprotected sandblaster to the complete lack of silicotic pattern in many molders and coremakers with over 40 years of exposure.

Until the past few years, these wide differences in the silicotic reaction were believed to be due largely to the varying percentages of free silica to which workers were exposed. The foundry silicosis hazard was thought to be low because the amount of free silica dust generated was relatively low. That the non-silica components of foundry dust were of any more importance than merely as diluents was not generally considered until the recently published investigations by Emmons and Wilcox⁹ and those by Denny, Robson and Irwin.¹⁰ In these studies both groups of investigators have arrived at the very fundamentals of the cause of silicosis and their contributions are of unusual interest. For practical purposes, how-

* Comparisons of the non-dusty, non-silicotic, and silicotic groups had been contemplated for the following items: weight, blood pressure, nasal obstruction, chest expansion, heart size, vascular changes, pleurisy, bronchitis, emphysema, blood Wassermann tests. The results were so inconclusive, however, on account of the age differences that this data will not be published until more adequate age corrections can be made.

ever, the carbon and calcium components of foundry dusts are not believed to be of significant importance compared to the number of free silica particles inhaled. Certainly the foundry dust hazard will not be solved by increasing the carbon or calcium particles or by adding aluminum to the dust now generated. It can be controlled only as is being done today; namely, by controlling the dust at its source when the silica content is known to be harmful. The only reliable check of the effectiveness of such control will continue to be preemployment examinations with chest X-ray and similar periodic examinations of those exposed.

CONCLUSIONS

1. Some 4,000 foundry employees have been studied, not only for lung changes but for general physical changes as well.

2. With half of the total group having had less than 10 years of foundry exposure, about 7 per cent with definite silicosis were found.

3. Of the 279 with silicosis, 60 (or 22 per cent) had tuberculosis which either was definitely active or in which activity was indeterminate. In 8 of these (or 3 per cent of the silicotics), there was definite activity of the tuberculosis.

4. Serial observations have suggested that silico-tuberculosis as seen in foundry workers is primarily a reactivation of a previously acquired but walled-off tuberculosis.

5. Simple silicosis as seen in foundry workers is only very slowly progressive, so much so that no visible changes have appeared in 4 years of observation. Moreover, the simple silicosis among these workers is only rarely

sufficiently advanced to cause symptoms and incapacity for work.

6. These studies suggest that the tuberculosis rate, among foundry workers at least, is not raised by dust exposure *per se*, but rises only after silicosis becomes definitely established.

7. Control of the foundry hazard is believed to be best accomplished by elimination at its source of the dust generated by sandblasting, sand chipping, sand grinding, and shake-out operations. Combined with this, preemployment and periodic examinations are essential so as to prevent tuberculous individuals from carrying on a dusty trade and to discover new infection and reactivation cases as they arise.

Development of an Industrial Hygiene Program in a State Health Department*

H. F. EASOM, M.D., AND M. F. TRICE

Director, and Engineer, Division of Industrial Hygiene, State Board of Health, Raleigh, N. C.

A SERIES of unusual developments culminated in the establishment of a Division of Industrial Hygiene as an administrative department of the North Carolina State Board of Health. For that reason its organization is not entirely typical of the developments that usually underlie the creation of a public health activity.

SUMMARY OF EVENTS

The first of the many incidents responsible for the birth of the division was the suit of an asbestos worker brought to court in 1934 to recover for damages resulting from pulmonary asbestosis alleged to have been caused by the inhalation of fine asbestos dust. This action was brought by a man named McNeely; the case has since become more or less celebrated in the annals of legislation involving occupational diseases. At that time disablement by an occupational disease was not compensable by statute although prior to this action the courts had adopted a liberal construction of the compensation laws.

The McNeely case served to emphasize the inadequacy of our laws with respect to the disabling of workers in industry, and so the following year

the Workmen's Compensation Act was amended to provide for the compensation of persons disabled by an occupational disease. The amendment stipulates that incapacitation by any one of twenty-five diseases and conditions¹ "shall be treated as the happening of an injury by accident" and thus compensable. The amendment was ratified on March 26, 1935.

For the administration of the amendment a sum of \$10,000 was appropriated. It early became apparent, as will be subsequently revealed, that this amount was insufficient to provide the services required by the new law. In their dilemma the Industrial Commission, administrator of the Compensation Laws, sought assistance and guidance from federal agencies with the result that there were enlisted the resources of the U. S. Public Health Service as well as those of the North Carolina State Board of Health. The situation appealed strongly to the State Health Officer, who saw in it an opportunity to extend the benefits of preventive medicine to approximately a million persons engaged in industrial pursuits and at the same time render a valuable service to industry.

The negotiations which followed culminated in the Industrial Commission placing the appropriation at the disposal of the State Health Officer for use in establishing a Division of Industrial

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

Hygiene as a department of the State Board of Health. At the time of this action it was anticipated that federal aid to states would become available with the passage by Congress of a Social Security finance bill. The U. S. Public Health Service promised to subsidize from such funds this new public health activity. This promise of assistance was largely responsible for the action of the Industrial Commission. Although supported in part by the Industrial Commission, The Division of Industrial Hygiene is a regularly constituted department of the State Board of Health and is under the complete control and direction of the State Health Officer.

PERSONNEL DEVELOPMENT

The Division of Industrial Hygiene became a reality in September, 1935, with the employment of a physician from the staff of the State Tuberculosis Sanatorium and a chemical engineer from the staff of the Division of Sanitary Engineering. Three months later, when office space has been allotted the new department, a secretary was added. Shortly thereafter the anticipated Social Security funds were received, and another physician and a medical technician were employed, both obtained from the State Tuberculosis Sanatorium. Thus, in less than a year the fledgling department became a 5 person division of the State Board of Health. Recently another physician and another engineer were added to the staff, so that as now constituted the division personnel numbers 7.

PROGRAM DEVELOPMENT

The burden of developing and initiating a program for the state was placed in large measure upon the shoulders of Dr. R. R. Sayers and his associates in the Public Health Service. Preliminary work indicated that siliceous dusts constitute the most extensive occupational disease hazards in the state. Accord-

ingly, a survey was made of a representative number of plants in each industry in which workers were thought to be exposed to siliceous dusts.²

The importance of a preliminary survey cannot be over-emphasized. It provides a conception of the nature and scope of a problem that can be obtained in no other way. Some data extracted from the summary of the report of the survey are presented as follows:

The report is based upon data representing 138 industrial establishments. . . .

The survey involves 5,608 persons of whom 94.5 per cent are males. . . .

Welfare activities are supported by only 20 per cent of the industries surveyed, 36 per cent of the workers, however, participate. Sick benefit provisions are available to only 5 per cent of the workers, and only 10 per cent of them participate with employers in providing group life insurance.

There are very meager, or no, first-aid supplies in 20 per cent of the plants surveyed; 10 per cent of the workers involved are thus denied the protection of elementary health safeguards.

Fifty-five per cent of all workers involved are exposed to siliceous dust hazards. In the respective mica, talc, and asbestos textile industries more than 75 per cent of the workers are exposed to siliceous dusts.

Measures for the control of dusts are provided for only one-fourth (25.7 per cent) of all workers that are exposed. This does not mean that approximately one-fourth of the workers are provided with measures that protect them; in many instances credit for dust control measures is given for devices that provide little or no protection.

In some plants the health of other workers is endangered by flagrant practices such as sand blasting in main workrooms.

In conducting the survey the health aspect of the problem was paramount at all times as is evidenced by the collection of such accessory data as that pertaining to welfare activities, sick benefit provisions, and the availability of first aid supplies.

PROGRAM INFLUENCED BY REQUIREMENTS OF WORKMEN'S COMPENSATION ACT

The program of the division from its

inception has been determined largely by the requirements of the statutes as regards the administration of the occupational disease amendment to the Workmen's Compensation Act. This legislation stipulates that the Industrial Commission shall designate by order each industry in which the workers are exposed to the hazards of asbestosis and silicosis. Furthermore, it states that the Industrial Commission shall make studies and recommendations with a view to reducing or eliminating such hazards. The work incident to performing such duties would be identical with the normal functions of an industrial health department, so that in these respects the requirements of the Industrial Commission coincide with the duties that routinely would be performed by the Division of Industrial Hygiene. However, the administration of the Act requires, in addition, that persons about to accept employment in such industries be given preemployment examinations to determine their suitability for employment involving exposure to the hazards of asbestosis and silicosis. The industrial Commission has accepted responsibility for such examinations, which are performed by the Division of Industrial Hygiene.

ACTIVITIES OF THE DIVISION

While still a fledgling department, the Division of Industrial Hygiene has undertaken an ambitious program, the extent of which has been largely due to, and even made possible by, the splendid assistance rendered by the U. S. Public Health Service.

During the first year of its existence the personnel of the division assisted U. S. Public Health Service workers in making studies of the occupational disease hazards in two major industries. During these investigations almost 1,500 workers were examined, and several hundred dust counts were

made. This work provided invaluable training in the technic employed in executing studies of this character.

In addition to this coöperative work several independent investigations have been made. A study of the occupational disease hazards associated with foundry and machine shop employment was initiated as the first major activity. This was followed by an extensive study of the mining and milling of pyrophyllite, a talc-like mineral, and steatite, which is true talc. More recently there was begun a study to evaluate the occupational disease hazards involved in the quarrying and crushing of granite, there being numerous quarries in the state.

In addition studies have been made which include newspaper establishments, brick plants, and a cotton mill. With the exception of the newspaper establishment, all investigations have involved the collection of both medical and engineering data.

TECHNIC EMPLOYED

The medical examination given a worker is rather thorough. In every instance an endeavor is made to obtain an accurate medical and occupational history. In the physical examination particular attention is given the cardio-respiratory system. A chest X-ray is made of each worker examined. Frequently, whenever there are symptoms of serious lung pathology, stereoscopic films are made. Whenever indicated, sputum, blood, and urine are subjected to laboratory analysis. A routine examination requires from 20 to 30 minutes to complete, depending upon the condition and intelligence of the worker.

In the quantification of atmospheric dust the Greenburg-Smith impinger apparatus and the refined methodology of the U. S. Public Health Service have been employed.

CONDITION OF WORKERS

The medical examinations have resulted in some interesting disclosures. Since the organization of the department a total of 4,537 workers have been examined, 1,858 (37 per cent) of whom were preemployment cases, the remainder being routine examinations of regularly employed personnel. Only 42 workers given preemployment examinations were rejected outright; 29 others were continued on a temporary basis until further examination could be made. Among the 4,537 workers examined the significant pathology discovered was limited. The more serious conditions diagnosed and the number of persons suffering from each are presented in Table I.

Summarizing, 483 or approximately 10 per cent of those examined exhibited evidence of pathology in the lungs and 3.5 per cent had high blood pressure and various types of heart disease. The most widely distributed defects, however, are those involving the oral cavity, which are not covered by the foregoing summary. There was found a high incidence of decayed teeth and diseased gums.

GENERALIZATIONS BASED ON
ENGINEERING STUDIES

Our engineering work has substantiated most of what has been published with respect to the effectiveness of the commonly employed devices and measures for the control of occupational disease hazards. Consequently, no enlargement of that phase of our program is attempted. The workroom studies have emphasized, however, that too little has been said about the value of good housekeeping. In many of the plants visited it was glaringly evident that cleaning up the workrooms and putting away equipment in an orderly manner would have contributed to a reduction in the atmos-

pheric content of some undesirable substance. Especially is this true of the dusty industries, in most of which there was found several days' accumulation of dust under machines that generate it, deposits of dust on overhead structural members, and dust upon odds and ends placed helter-skelter about the workrooms. Such accumulations yield to the atmosphere particles of dust with every passing breeze and with every vibration of the building.

The engineering activities, especially, have demonstrated that an educational program is mandatory. Many of our employers are not aware of the existence of occupational disease hazards in industry. The subject is entirely new to them, and for that reason they must be acquainted with some of the fundamental facts that have been uncovered in recent years by industrial hygiene investigations. A part of such an informative program is to convert them to the belief that a clean and orderly plant and safe working conditions pay dividends in better morale and in increased efficiency. It is believed that once a manufacturer can be induced to enforce good house-keeping practices in his plant it will be easier then to sell him on the idea of installing effective

dust control safeguards. A program of education is likely to accomplish results where big stick methods would fail.

POLICY

The examination of large groups of people emphasizes the fact that the human race is still far from perfection. In fact, so large a percentage of the people encountered have infirmities of one kind or another that decisions relative to their fitness for employment must be based on a rational policy that is equitable alike to employee and employer. Many conditions are found which most certainly should be corrected, but which need not prevent the employment of afflicted persons. In every case of this kind the worker is advised to seek treatment from a local physician. Those found to have active pulmonary tuberculosis or extensive healed lesions are rejected or, if already employed, are removed from the industry. Those having syphilis, are so informed and reported to the county health officer. They are allowed to continue working. In any event, every effort is made to keep a person gainfully employed. A worker is never recommended for dismissal if there is any place where he may work safely. The discovery of lung pathology is not necessarily grounds for discharge. In certain cases a worker is permitted to continue in employment but is subjected to periodic examinations to determine the trend of the ailment. In the event a worker already employed is found to have defects which make a change in jobs advisable, both the employee and the employer are notified. In such cases suggestions are made relative to the type of work the employee may perform safely. The policy employed in handling certain groups of asbestos and foundry workers, which cases have become classics in the annals of compensation and industrial

hygiene experience, is certainly *not* an equitable procedure and is not the basis for action in North Carolina.

It has become evident, that it is difficult to predict just how a person will react to an occupational environment. There seems to be a certain amount of individual susceptibility or immunity.

A report on every person examined prior to employment is sent the employer with copies going to the Industrial Commission and to the Compensation Rating and Inspection Bureau. Combined engineering and medical reports are sent to these departments and to the Labor Department as well. Such practice makes duplication of work unnecessary and permits the division to be of maximum service to all agencies concerned.

COÖPERATION

The intimate association that exists between the State Board of Health and the Industrial Commission is occasioned, as has been indicated, by a conjoint administration of a state law. However, there are other state departments not bound by such ties that recognize the public health problems involved and so depend upon the State Board of Health for data with respect to occupational disease hazards, especially is this true of the Department of Labor. A most amicable and coöperative liaison exists between the State Board of Health and all other state departments that are concerned with the problems of industrial hygiene.

Revised Fuchsin Lactose Broth for the Confirmatory Test in Water Analysis*

CASSANDRA RITTER

Bacteriologist, State Board of Health, Lawrence, Kans.

AN important factor in bacterial water analysis is the confirmatory test. It is used as a necessary step after the presumptive test, verifying the evidence of the presence of coliform organisms given by a positive presumptive reading. Especially do the large number of presumptive positives which are not caused by coliform organisms make the confirmatory test valuable in routine analysis.

For making the confirmatory test, only the solid plate media, eosin methylene blue agar and Endo agar had been recommended until 1936 when 4 liquid media were listed in the 8th edition of *Standard Methods of Water Analysis*.¹ These media, all containing dye or some other inhibitory agent, are brilliant green bile, crystal violet lactose broth, formate ricinoleate broth, and fuchsin lactose broth. Any one of them can be used for the confirmatory test instead of the solid plates. These 4 liquid confirmatory broths were recommended after a coöperative study of selective media for use in water analysis was made, and reported by Ruchhoft.^{2, 3}

The optimum concentrations of inhibitory agents and other ingredients of these media have been determined by

various workers. Levine,⁴ by counting the viable cells after 7 hours' incubation of the test medium found that bile in 0.5 per cent peptone water accelerated the growth of the colon group. Dunham and Schoenlein⁵ determined the effects of various amounts of brilliant green and of bile to be used in the brilliant green bile confirmatory medium, by similar methods. Stark and Curtis⁶ studied brilliant green bile by observing the effect of each substance on various organisms.

A thorough study of lactose fermenting bacteria not belonging to the colon group but at times interfering with their isolation, was made by Greer⁷ and others. They found *Cl. welchii*, *B. aerosporus*, and *Streptococcus fecalis* commonly present in water, and *Ps. pyocyaneus*, and several others sometimes present.

Fuchsin lactose broth⁸ was developed as a presumptive medium containing 0.015 per cent basic fuchsin added to lactose broth prepared by the Standard Methods formula. The inhibitory dye was intended to be added in such an amount that organisms causing false positive presumptive tests would not grow, and coliform organisms would. The present study was undertaken to determine how much basic fuchsin could be used in a confirmatory fuchsin lactose broth.

The inhibitory effect of varying con-

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

centrations of basic fuchsin in a lactose broth medium for pure cultures of *Escherichia coli* and *Acrobacter aerogenes* was studied. The basic medium was Standard Methods lactose broth; the Difco dehydrated product was used throughout to secure uniformity. The basic fuchsin used was that having the certification number CF-15, selected as the standard for this medium. It was prepared in 0.1 per cent aqueous solution and varying amounts added to the lactose broth, which was then tubed in 10 ml. quantities. A suitable dilution of a 24 hour culture of the test organism was made in buffered dilution water, so that inoculation with a standard loop resulted in a uniformly small number of organisms. The tubes were incubated in a water bath at 37° C. for 7 hours, then removed and plated on agar. Plates were counted after 48 hours incubation at 37° C.

The results of a series of tests are presented as an average in Table I

TABLE I

Effect of the Concentration of Basic Fuchsin on the Growth of Escherichia coli in Lactose-Peptide Broth

420	0.035	118,000	51.1
420	0.04	10,300	89.5

In media containing 0.015 per cent basic fuchsin, the present formula, the dye is moderately inhibitory, as shown by the lengthening of the generation time from 23.9 to 24.9 minutes. Dye in the amount of 0.025 per cent is more inhibitory, the organisms grown in it having a generation time of 30.8 minutes. Larger amounts of basic fuchsin are decidedly inhibitory to this strain of *Escherichia coli*.

In Table II the results of the experiments using *Acrobacter aerogenes* as the test organism are shown.

TABLE II

Effect of the Concentration of Basic Fuchsin on the Growth of Acrobacter Aerogenes in Lactose-Peptide Broth

Time Minutes	Per cent of Basic Fuchsin	Average Number of Bacteria per Milliliter	Generation Time Minutes
0		690	
420	0 (control)	64,660,000	25.4
420	0.015	58,000,000	25.7
420	0.02	60,000,000	25.6
420	0.025	33,000,000	27.0
420	0.03	35,000,000	26.8
420	0.035	17,600,000	28.7
420	0.04	28,500,000	27.4

The inhibition caused by these amounts of basic fuchsin was much less marked than that for *Escherichia coli*; the generation time was not greatly lengthened, even with the largest amounts of dye used.

The effect of adding bile to the medium was studied similarly. Bacto-oxgall was added to lactose broth in 1 per cent and 0.5 per cent amounts, and tested without and with varying amounts of basic fuchsin. Preliminary determinations showed that the larger amounts of the dye solution used were insoluble in the bile-lactose broth medium, although the zone of inhibition had not been reached with 0.25 per cent added dye. Therefore, the use of 0.5 per cent bile was discarded. A medium containing 0.1 per cent dye and 1 per cent bile was selected for further tests.

In Table III is shown the stimulating effect of 1 per cent bile in lactose broth on the growth of *Escherichia coli* and *Acrobacter aerogenes*, and the fact that adding basic fuchsin in amounts practical to use is only slightly inhibitory.

After these preliminary experiments were made, 3 new formulae were selected for further tests. These were lactose broth containing 0.025 per cent

basic fuchsin; one containing 0.03 per cent basic fuchsin; and one with 1 per cent bile and 0.1 per cent basic fuchsin. These three media were used in parallel with Standard Methods fuchsin lactose broth containing 0.015 per cent basic fuchsin, and with brilliant green bile. Presumptive positive tubes in the following experiments were also confirmed by the Standard Methods completed test.

The reliability of the medium having a higher dye content was tested with pure cultures of lactose-utilizing organisms, both alone and in combinations. Besides *Escherichia coli* and *Aerobacter aerogenes*, organisms used were *Pseudomonas pyocyaneus*, *Bacillus aerosporus*, and a streptococcus, all freshly isolated from water; and *Clostridium welchii*, obtained from Dr. I. C. Hall. A 24 hour broth culture of these organisms was inoculated by standard loop into the 5 media and growth was observed.

Pseudomonas pyocyaneus grew in all the 5 media containing dye, producing cloudiness by 24 hours. The strain of streptococcus used did not grow in any of the 4 media containing fuchsin in 48 hours, but grew in the brilliant green bile in 24 hours. *Bacillus aero-*

sporus gave no evidence of growth in any tubes in 48 hours, but produced gas in broth containing 0.015 per cent basic fuchsin in two sets of tubes incubated for 72 hours. With *Clostridium welchii*, results were variable in the different series. In 16 sets of tubes, the 0.015 per cent fuchsin dye media was positive 5 times, although the amount of inoculum varied from 1/10 to 1/2 milliliter of broth culture, a larger amount than that used uniformly. Brilliant green bile showed gas 9 times, in the same series; none of the other media supported growth in these tests.

One ml. of a 24 hour culture of each organism excepting *Cl. welchii* was highly diluted in unsterilized tap water, so that when planted in lactose broth the 10 ml. portions would give positive results for the organism used, and 1 ml. portions would not. Combinations were obtained by mixing different amounts of the final dilution. The tap water was planted as a control, for every experiment. Positive presumptive tubes were confirmed in the 5 liquid media, and by the Standard Method. The positive confirmatory dye tubes were streaked on Endo or eosin-methylene-blue plates to observe the cultures surviving.

In every case, all the liquid confirmatory media were positive when the Standard Methods confirmation was positive. This was true for all presumptive tubes showing gas in 24 hours, but for none developing gas in 48 hours. False positive tests were shown only by the tubes containing media of 0.015 per cent dye content, in a few cases. These might have been caused by the organisms in the tap water.

The following additional observations were made:

With *Escherichia coli* and *Ps. pyocyaneus*, there was nothing distinctive in the amount of gas in the confirmatory tubes. Plates inoculated from these

tubes showed a preponderance of one organism unrelated to the proportions originally planted.

With *Escherichia coli* and *Bacillus aerosporus*, plates from positive dye tubes showed coli colonies only.

Combinations of *Escherichia coli*, *Ps. pyocyaneus* and *B. aerosporus* gave no new information. Presumptive tubes positive at 48 hours but not confirming showed *Ps. pyocyaneus* colonies on solid plates.

With *Escherichia coli* and the streptococcus, 48 hour presumptive tubes showed streptococcus alone on plate media.

DISCUSSION

Since a liquid confirmatory medium receives a fairly large inoculum of an actively growing mixed culture of water bacteria, and it is desirable to observe the presence of coliform organisms only, this observation is facilitated by the inhibition of the extraneous forms. A medium somewhat inhibitory to pure cultures of coliform organisms can theoretically be safely used for the transfer of presumptive positive cultures. This is shown to be true for the 3 new confirmatory media tested by the experiments with pure cultures of lactose-utilizing organisms, and by the

TABLE IV

Confirmations of 318 Positive Presumptive Tubes from 116 Water Samples

Media	Number of Confirmations		Number of Liquid Confirmations Positive by Standard Methods Test	
	from 24 Hour Presumptives	from 48 Hour Presumptives	from 24 Hour Presumptives	from 48 Hour Presumptives
0.015 per cent fuchsin broth	124	124	123	87
0.025 " " " "	123	91	123	85
0.03 " " " "	124	90	123	85
0.1 " " " "				
1 per cent bile broth	123	90	123	87
Brilliant green bile	123	91	123	87
Standard Methods completed test	125	86

A number of positive presumptive tubes from the routine analysis of water samples was confirmed in the same manner. The samples included waters of all degrees of pollution: raw and treated surface supplies, deep and shallow wells, springs, and swimming pools.

Table IV shows the results of tests on 116 samples.

Three hundred and eighteen positive presumptive tubes were confirmed in 5 liquid media, and by the Standard Methods completed test. Positive confirmatory tubes were also completed. False positive confirmations were shown by standard fuchsin broth in 38 cases, or 15.3 per cent.

confirmation of presumptive tubes from water samples. In 3 cases only was a negative confirmatory test shown by these media when coli-aerogenes organisms were isolated by any other confirmatory method used.

The 2 dye broths containing the greater concentrations of fuchsin, 0.025 per cent and 0.03 per cent, can be compared only by observations of the amount and time of gas production, as the positive results in the 2 were the same. With 0.03 per cent dye, a smaller amount of gas tended to be formed by 24 hours, although it was not difficult to make a reading. This concentration was used as a method

of checking the effect of the smaller amount of dye, which it did adequately.

Gas production in both media containing bile was greater than in the other tubes. Since there was no difficulty in reading any positive results, this is no particular advantage. The demonstration of fewer *Ps. pyocyaneus* organisms in the bile media is suggestive of its usefulness.

These tests show the advantages of fuchsin broth of 0.025 per cent dye content over brilliant green bile. The strain of streptococcus grew readily in the brilliant green bile; but the work of Stark and Curtis, who used 8 strains of streptococcus, demonstrated that 3 of them grew in that medium. *Cl. welchii* was inhibited only half the time in brilliant green bile and 0.015 per cent fuchsin lactose broth, but always in these experiments in the other fuchsin media.

The superiority of 0.025 per cent dye over 0.015 per cent dye, in fuchsin lactose broth, is shown by the cases from water samples, in which 0.015 per cent dye broth gave 15.3 per cent false positive results. The pure culture studies with *Cl. welchii* and *B. aerosporus* also indicated that the inhibition

from 0.015 per cent dye was not sufficient.

CONCLUSION

The basic fuchsin content of fuchsin lactose broth should be increased from 0.015 per cent to 0.025 per cent when the broth is to be used as a confirmatory medium in water analysis. Evidence is presented which would indicate that fuchsin lactose broth containing 1 per cent bile and 0.1 per cent dye is also a satisfactory confirmatory medium.

Abortion and the Public Health*

REGINE K. STIX, M.D., AND DOROTHY G. WIEHL, F.A.P.H.A.

Milbank Memorial Fund, New York, N. Y.

RECENT special studies of maternal mortality have shown that from one-fourth to one-third of all maternal deaths are associated with abortion.^{1, 2} These findings have stimulated wide interest in the problem of abortion from the point of view of the public health, and especially in the problem of the frequency with which abortion occurs. The question naturally arises whether abortions occur in a similarly large proportion of pregnancies, with a death rate approximately the same as that associated with other types of pregnancy termination, or whether these abortion deaths represent an abnormally high death rate for a small number of abortions. Obviously it is impossible to answer this question without having reliable information on which estimates of the number of abortions in the population as a whole can be based. Registration of previable terminations of pregnancy is not required in most states, and if required, as in New York City, they are very incompletely reported.

Recently several surveys have been undertaken by the Milbank Memorial Fund in which a physician or a nurse obtained complete pregnancy histories from women in their own homes. Two of the groups interviewed had been clients of birth control clinics, one in New York City³ and the other in

Cincinnati, Ohio. A third group consisted of an unselected sample of married women in New York City⁴ who had had a pregnancy which terminated within a few months of the interview. In each case the interviewer had the means of establishing a good contact with the surveyed case, either as a representative of the clinic from which the woman had sought advice or as a public health nurse interested in the problems of a recent delivery. Both the clinic groups and the survey group were selected with respect to overt fertility and the clinic groups showed an additional selection with respect to a special interest in the control of that fertility.

The outcome of pregnancies reported by the women interviewed in these three studies is compared with data from various other sources in Table I. For those groups for which information concerning the comparative prevalence of spontaneous, therapeutic and illegal abortions is available, there is a striking lack of variation in the incidence of involuntary abortion.[†] In 6 of the 7 instances in which the proportion of pregnancies terminating in involuntary abortion is known, the variation is less than 2 per cent.[‡] The consistency

[†] The term involuntary abortion includes both spontaneous and therapeutic abortions.

[‡] The low proportion of spontaneous abortions reported by patients of a New York City birth control clinic is partly dependent on the extraordinarily high proportion of illegal abortions, since illegal abortions are usually performed very early in pregnancy, before the period in which spontaneous abortion is most likely to occur (see Reference 3, p. 361).

* Read at the Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

* The studies on which the major portion of this report is based are indicated in capital letters. Numbered references pertain to publications listed in bibliography at end of paper.

^a Includes therapeutic abortions, except as indicated.

^b Unpublished data from studies of the Milbank Memorial Fund.

^c Unpublished data from the private practice of Dr. Lovett Dewees, analyzed by Gilbert Beebe. Personal communication.

** The proportion of abortions among the current hospital births is almost certainly much lower than among pregnancies in the general population, since the hospitalized abortions will be chiefly those accompanied by a definite morbidity and therapeutic abortions. It may be estimated that the wastage among previous pregnancies of these women would be about 18 per cent for the New York women and 16 per cent for the Chicago group.

† Includes therapeutic abortions and 1.1 per cent unspecified abortion.

of these figures suggests that an average involuntary abortion rate of about 10 per cent of all pregnancies may be expected in any given population group and, therefore, with a known number of non-viable pregnancy terminations,

the incidence of illegal abortions may be estimated with considerable accuracy.

Contrasted with the similarity of figures on involuntary abortion, there is a wide variation in the reported incidence of illegal abortion in these

groups. The lowest incidence is reported by Pearl's group of multiparous patients in Chicago hospitals,⁷ and the highest by the group which attended the New York birth control clinic.³ Patients seeking advice on contraception in other cities had illegal abortion rates which were higher than those of women unselected with respect to an interest in limiting their families, but much lower than those reported by the New York clinic patients. Data for the non-clinic groups suggest that 5 per cent is a fair maximum estimate of the proportion of pregnancies terminated by illegal abortion among married white women.¹³ Higher estimates of the prevalence of illegal abortions have been based very largely on figures from the histories of women who attended the same New York birth control clinic for which data are given

in Table I.^{14, 15} This clinic group does not appear to be typical of either an average unselected group of urban married women or of clinic patients in other cities.

The per cent of pregnancies terminated by illegal abortion shows considerable variation with order of birth and income, and varies widely in these respects in the three groups studied. The variation by order of birth is contrasted with the lack of variation in spontaneous abortions by the same type of analysis in Figure I. Not only does the percentage of pregnancies terminated by illegal abortion vary widely in the three groups, but they show differing characteristics with respect to order of birth. The New York birth control clinic sample, like other samples from the same clinic, shows a marked rise in illegal abortion with increasing

FIGURE I

order of pregnancy. The Cincinnati birth control group shows a similar but much less marked rise up to the fourth pregnancy, after which the proportion of pregnancies illegally aborted tends to remain almost level. The same type of rise is observed in the New York City unselected group up to the third pregnancy. After the third pregnancy the percentage appears to drop, but the number of cases is too small to give dependable evidence on this point.

Variation of illegal abortions with family income is shown in Figure II. The variation is not so marked as that associated with increasing order of pregnancy, but the differences between the three survey groups persist. In both birth control clinic groups there is a rise in abortion rate associated with rise in income, while in the unselected New York City group, there is a rise only in one group, the poorest non-relief group. It appears from these analyses that the pressure of increasing pregnancies and certain economic and social pressures, while they appear to have no influence on the involuntary abortion rate, are important factors underlying the resort to voluntary induced abortion.

The total number of abortions occurring annually in New York City may be estimated on the basis of the ratio of abortions to live births reported in the unselected New York group.⁴ This estimate is probably quite accurate for spontaneous abortions and a minimum estimate for induced illegal abortions. The approximate number of abortions in New York City, estimated on this basis, is more than 20,000 annually, of which between 5,000 and 6,000 are illegally induced. Referring these figures to the classification of maternal deaths in the special study of deaths for 1930-1932 by the New York Academy of Medicine,¹ the indicated risk of mortality for women in the first and second trimesters of pregnancy, exclusive of ectopic pregnancy and illegal abortion, is 7 per 1,000. The rate is almost exactly the same for women experiencing illegal abortion. This rate is slightly lower than the rates reported in several series of hospital cases.^{16, 17, 18} It is almost twice as high as the rate of 4 deaths per 1,000 confinements for women delivered in the third trimester of pregnancy.

The distribution of causes of death

* Pre- and postpartum.

differs widely for the two types of abortion. Ninety-seven per cent of the deaths associated with illegal abortion were due to puerperal infection. Half the deaths associated with spontaneous and therapeutic abortion, however, were due to causes other than infection, the most important of which were toxemia and extrapuerperal diseases. This is readily understandable in deaths following therapeutic abortion. In deaths following spontaneous abortion, it appears that the systemic disease responsible for the maternal death was first responsible for the abortion. This is peculiarly true of influenza and pneumonia in pregnant women, and probably also true of other types of systemic disease; in other words, the

disease kills first the fetus and then the mother.

Information concerning the morbidity associated with each pregnancy termination was available in the New York and Cincinnati studies of women who had attended birth control clinics. The reported morbidity is doubtless low, and of a relatively serious nature, since it is reported by the women as history, rather than taken from a medical record of the pregnancy. It must be borne in mind, however, that it was not sufficiently serious to cause either death or sterility, since the records are those of surviving, fertile women. Thus, the type of puerperal infection reported was not just pyrexia, which in hospital series is assumed to be the diag-

FIGURE III

* The morbidity rate for all abortions is adjusted to the proportions of spontaneous, therapeutic and illegal abortions reported by the unselected group of New York women.⁴

nostic feature of a septic case, but an infection sufficiently severe to be remembered as a temporarily incapacitating illness.

Figure IIIa and Table II show separately for illegal abortions and for spontaneous abortions the rates for morbidity reported in the histories of the two groups of clinic patients. Some morbidity prepartum was reported in 7 per cent of the spontaneous abortions, but in only 2 per cent of the induced

abortions. It is clear that the women who experienced spontaneous abortions presented a greater risk at the time of the abortion than did those who experienced an illegal abortion.

A morbid condition postpartum was reported in about 10 per cent of the spontaneous abortions and in about the same per cent of illegal abortions. The type of morbidity varied, however, in that puerperal infection was associated more than twice as often with illegal

abortion (2.3 per cent) as with spontaneous abortion (1.0 per cent). Since puerperal infection was the cause of 75 per cent of all reported abortion deaths, infection is obviously the factor of the greatest concern to those especially interested in the public health aspects of the abortion problem.

Comparison of abortions in which there was some instrumental interference, usually dilatation and curettage, and those in which there was none shows that the risk of puerperal infection was about four times as high in those cases in which there was instrumental intervention as in those in which there was none (Figure IIIb). This was true both in spontaneous abortion followed by dilatation and curettage and in criminal abortion. The figures are nearly parallel for the same management in the two types of abortion. The total proportion of infected cases associated with illegal abortion was twice as high as the proportion following spontaneous abortion, however, because there was some instrumentation in more than nine-tenths of the illegal abortions, but in only about one-third of the spontaneous ones. The rate of infection for spontaneous abortions followed by curettage was the same in Cincinnati as in New York, but it is worthy of note that, while in the New York group half the cases of spontaneous abortion were followed by dilatation and curettage, this was true of only about one-fourth of the Cincinnati cases, and the incidence of infected cases in the total number of spontaneous abortions was just half as high in the Cincinnati as in the New York group. This finding confirms the observations of a number of other authors^{15, 18, 19, 20} who have concluded from studies of abortion cases in hospitals that conservative treatment of abortion presents far less risk than instrumental interference.

It has been widely assumed that

there is little or no risk of puerperal infection in non-criminal abortion. The figures from these studies point to a very definite risk when the abortion is followed by dilatation and curettage, and a slight risk when there is no operative interference. The risk of infection should be much lower in the instrumental treatment of spontaneous abortion than in the hands of the abortionist; but two factors may be present in spontaneous abortion cases which may contribute to septic morbidity and mortality: (1) Curettage following spontaneous abortion is frequently done in the home of the patient rather than in a hospital; and (2) the woman experiencing a spontaneous abortion presents a greater risk than the woman presenting herself for illegal abortion, because of the more frequent prepartum complications which are in themselves responsible for the spontaneous abortion.

From the point of view of the public health, prevention of abortion morbidity and mortality is the primary concern. What means of prevention can be devised? Spontaneous abortions may be prevented to some extent by careful management in cases in which the patient consults a physician in the early weeks of pregnancy. Taussig,¹⁵ in his text on abortion, has an excellent chapter outlining the measures which may be used both before and after conception. When abortion is inevitable, both morbidity and mortality can probably be reduced by conservative management and the avoidance of curettage whenever possible.

Theoretically all morbidity and mortality from illegal abortion is preventable and unnecessary. The phenomenon of a rapidly declining birth rate, however, is the expression of a widespread desire to limit the size of families. Population groups in the higher income brackets are enabled to limit the size of their families by the use of

reliable contraceptives. For population groups of low income, however, where economic pressure and inadequate housing are most acute, reliable contraceptive methods are not at present readily available. In these groups abortion offers a means of family limitation when inadequate contraception fails. Increased economic security and more adequate housing may decrease the acuteness of the need for family limitation in these groups. The establishment of maternal health clinics, which would make reliable contraception more readily available, would be a more immediate and direct approach to the problem.

Improved Laboratory Control of Pasteurized Milk*

WALTER VON DOHLEN TIEDEMAN, M.C.E., F.A.P.H.A.,
AND NELSON J. HOHL, M.S.

*Bureau of Milk Sanitation, State Department of Health,
Albany, N. Y.*

AMONG the laboratory tests utilized by health officials for the sanitary control of public milk supplies are the plate count, methylene blue reduction test, catalase test, acidity test, and direct microscopic count. Of these, plate counts have been most generally used beginning as early as 1893. Although these have proved to be useful in controlling quality, none of them have had a direct bearing on safety, which is the primary concern of health officials. In other words, none of the tests either revealed the presence of viable pathogenic bacteria in milk or showed whether the milk had been subjected to treatment that would surely devitalize any pathogenic organism likely to be milk-borne, that should chance to have been present prior to such treatment. Originally developed for the control of raw milk, these tests have proved to be even more indirect and uncertain indices when applied to pasteurized milk.

From its inception, the plate count has been in controversy due primarily to inconsistencies revealed by comparisons of results obtained by multiple examinations of split samples. A noteworthy attempt to overcome this, resulted in the appointment, in 1905, of a committee of the American Public Health Association, to formulate stand-

ard methods for the bacteriological examination of milk. The work of this committee has done much to standardize the technic of making agar plate counts.¹ Notwithstanding these efforts at standardization, results of agar plate counts today are anything but comparable.

Five years ago, the writers and their associates undertook a large scale comparison of standard plate counts made simultaneously by different laboratories. Ten selected large samples of milk were split into 80 portions and delivered under carefully controlled conditions to 74 laboratories throughout the state, approved by the State Commissioner of Health for making standard plate counts of milk. Several laboratories took more than one set of samples so that each technician examined a different set.

These samples were plated simultaneously at a predetermined time by 78 different technicians in these laboratories. The results² were illuminating.

Counts on samples of raw milk and pasteurized milk with normal flora were more consistent than those on abnormal milks, although on the most favorable of these, different laboratories reported counts varying from 1,000 to 30,000 and the least favorable from 1,500 to 1,000,000. The extremes on abnormal samples were no worse although the mass of results was more scattered. It is difficult for the layman to understand

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

these differences, and many have reacted by accusing the laboratory worker of bad faith.

Similarly, counts made on a sample of abnormal raw milk at the same time in the same laboratory, with conditions as nearly as possible the same but plated on samples of media submitted by 47 different laboratories, showed marked variations due particularly to erratic growth of the streptococci in mastitis milk and of thermophylic bacteria in a sample of cream. This confirmed work by Bowers and Hucker³ showing that standard media failed to support the growth of certain types of bacteria and the work of Pederson, Yale, and Eglinton⁴ showing that 37° C. is an unsatisfactory temperature of incubation, and that 32° C. is much better.

In view of this and other evidence that the technic for making standard plate counts is in need of drastic revision, there should be either a general demand on the part of health officials for such revision, or a general movement to discountenance and discontinue the use of such counts.

Using standard plate counts for what they may be worth, while making the mental reservation that they have not been worth while, health officials have been forced to depend largely upon the results of inspections to determine the safety of pasteurized milk. Inspections are necessarily infrequent, leaving intervals when almost anything might happen. It is also only natural for plant operators to do their best while an inspector is in the plant, leaving him in "the dark" as to what might happen when he is not there. There has been a great need for a test to be applied to the final product that will show whether or not it is safe.

In an effort to find something more useful than the standard plate count, we turned first to the test for coliform

organisms.⁵ The tests showed that these organisms which were almost invariably present in raw milk, seldom survived pasteurization, and that in most instances the presence of coliform organisms in 1 ml. portions of pasteurized milk by the presumptive test indicated either improper pasteurization or contamination subsequent to pasteurization. This gave us something more definite to work on than the simple estimation of the total number of bacteria present in pasteurized milk. In fact, we found that not infrequently relatively low count milk gave this evidence of improper pasteurization or contamination.⁵ In using this test we could not be sure as to the significance of coliform organisms except in the examination of a series of process samples showing the absence of such organisms in a sample of milk taken from the pasteurizer at the end of the holding period and their presence at some later stage.

Like many health officials, for some time we have hoped that a satisfactory test for pasteurization was "just around the corner." When reports published several years ago^{6,7} indicated that the amylase test for pasteurization was satisfactory, we put it to the "acid test" and found that comparable results could not be obtained on split samples.

Our experience during the past year and a half with the latest development, namely the phosphatase test, has been very encouraging. The results have indicated that the phosphatase test will differentiate properly pasteurized from improperly pasteurized milk with a high degree of precision.

The test used is that of Kay and Graham⁸ as modified by F. W. Gilcreas.⁹ Through the use of this test on samples of milk and cream we have found raw milk and cream "masquerading" under pasteurized labels, and have detected different degrees of

under-pasteurization and dilution of pasteurized milk and cream with raw milk and cream. In all of these cases showing under-treatment inspections were made at the pasteurizing plants which almost invariably revealed the cause of the trouble. These were things that the most careful inspections and repeated standard plate counts had failed to reveal. It looked as though the time consumed in making standard plate counts had been largely wasted and that routine inspections were far from satisfactory. This led us to the development of an improved laboratory control of our pasteurized milk supplies. It appeared that by frequently subjecting surprise samples of pasteurized milk and cream to examination, (a) by the phosphatase test to determine proper pasteurization, (b) by test for coliform organisms to indicate possible contamination after pasteurization, and (c) by direct microscopic count to determine care in handling, we would have a true index of the safety and sanitary quality of our public supplies. Armed with the results of such tests, the milk sanitarian can go to the pasteurizing plant, and in most instances quickly determine and eliminate the source of the trouble.

Both our mobile laboratory parties are following this procedure. Samples of the various grades of milk and cream are collected at the pasteurizing plant or from the delivery truck. It is generally possible to obtain samples that were pasteurized on the day previous to the visit, and samples pasteurized on that day. We are also experimenting with the shipment of samples by mail for examination, preparing the slide for direct microscopic examination at the time of sampling. The practical value of this improved control and the futility of control by standard plate count are demonstrated by an actual occurrence.

A health officer maintaining control

of pasteurized milk by the standard count, revoked the permit of dealer "A" to sell pasteurized milk, because of repeated standard plate counts in excess of sanitary code limits for the grade, but issued "A" a temporary permit to sell milk pasteurized at the nearby plant of dealer "B" whose record showed satisfactory standard plate counts. "A" had sent samples of his pasteurized milk to a private laboratory during the time the municipal laboratory was reporting high counts in an effort to discover the cause. The private laboratory reported standard plate counts on these samples which were within the limits prescribed by the sanitary code for that grade, and indicated that conditions were satisfactory. By chance, samples were collected from "A's" plant by our mobile laboratory party during the last days of operation before the suspension of his permit. The direct microscopic examination of these samples of milk revealed the presence of large numbers of bacteria morphologically resembling thermophiles. The phosphatase test and coliform examination indicated that the milk was satisfactorily pasteurized and not recontaminated after pasteurization.

A few days after "A's" permit had been suspended, and while "B" was pasteurizing his milk, similar samples were collected by our representatives at "B's" plant. The phosphatase test on these samples, indicated that the milk was grossly underpasteurized. An investigation revealed that a 12 hour recording thermometer chart was being used on a recording thermometer built for 24 hour charts, and that the operator was determining holding time by looking at the chart. It is obvious that when the chart showed 30 minutes holding at pasteurizing temperature, the milk had actually been held only 15 minutes. This was immediately corrected, but for some time

improperly pasteurized milk had been sold as pasteurized undetected by standard plate count or inspection.

In his effort at control by standard plate count, the health officer had unwittingly converted a safe supply of pasteurized milk into a decidedly unsafe one.

Further investigation of "A's" plant, showed that repasteurization of returned milk had been responsible for the development of thermophilic bacteria. This was easily corrected. Probably the cause for the difference in standard plate count by the municipal and private laboratories was some slight difference in media or in temperature of incubation. If both laboratories had supplemented these counts with direct microscopic examinations the cause would have been detected.

The survey in this city as a whole showed that the supply of pasteurized milk and cream was, with a few exceptions, satisfactory as determined by standard plate count. However, the phosphatase test and coliform test showed that considerable milk and cream labeled pasteurized, was being sold that was not pasteurized, or had been contaminated after pasteurization, or both.

Just a few words of caution may be in order. The phosphatase has not as yet been adopted as a standard method of milk analysis, although steps are being taken to have it tested and recognized if found satisfactory. We confidently expect that this will be done before long. Until the test is recognized, it may be advisable to use it for information and correction rather than as a basis for court action.

Also, occasionally coliform organisms may survive pasteurization. The finding of these organisms in pasteurized milk and cream cannot be taken, therefore, as positive evidence of contamination except when process samples are taken—a sample taken directly from

the pasteurizer indicates absence of these organisms, and a sample taken from some subsequent stage in the process indicates their presence.

In interpreting the results of the direct microscopic count of pasteurized milk and cream, some prominent workers have concluded that most of the bacteria that take the stain are living organisms.¹⁰ Whether living or dead, the presence of excessive numbers indicates that the milk or cream was of poor quality before pasteurization, that thermoduric bacteria have survived or thermophilic bacteria developed during pasteurization, that growth of bacteria had occurred after pasteurization, or that contamination had occurred subsequent to pasteurization, any one of which is undesirable.

The intelligent use of this improved laboratory control opens new fields for protecting public health through the economical development of safe pasteurized milk supplies of good quality.

Supervision of Fumigation and Extermination*

JOHN OBERWAGER, M.D., F.A.P.H.A.

*Director, Sanitary Bureau, Department of Health,
New York, N. Y.*

THE exterminator of today must have a knowledge of entomology, chemistry and sanitation. The physician and the engineer must accept the responsibility of training exterminators and fumigators for the proper performance of the health work in which they are engaged.

SUPERVISION IN NEW YORK CITY

Supervision of fumigation has become a public health problem in all large cities because of two facts: the greatly increased use in the past few years of toxic gases for the destruction of insects, vermin, and rodents; and the large number of individuals, partnerships, and corporations now engaged in the business of exterminating such pests.

In New York City 53 concerns hold permits to conduct the business of fumigation and extermination; and 240 hold permits solely for the business of extermination. In addition, 96 employees have fumigation licenses and 509 have extermination permits. From June 1, 1936, to June 1, 1937, there were 353 fumigations performed in the City of New York under the supervision of the Sanitary Bureau of the Health Department.

In order to prevent poisoning from improperly conducted exterminations and fumigation operations, Dr. Rice, Health Commissioner, forwarded to the Board of Health of the City of New York in May, 1937, recommendations to amend the Sanitary Code and regulations thereunder controlling this business. The modifications were the result of a study conducted over a period of several years. The laws on this subject in other cities in the United States and Canada were carefully studied in order to benefit by the experience of other health authorities.

The changes in the recently adopted law in this city are concerned principally with the following:

- (a) The method of reporting fumigations to the Department of Health
- (b) The insurance of the safety to occupants of premises during and following fumigation
- (c) The use in fumigation of gas masks and canisters approved by the Bureau of Mines
- (d) The use of sodium fluoride in extermination in food establishments

The Sanitary Code of the city defines a fumigant as any substance which by itself or in combination with any other substance emits or liberates gas, fumes, or vapors, and which gas, fumes, or vapors when liberated and used for the destruction and control of insects, vermin, rodents, or other pests, are

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

poisonous, noxious or dangerous to human life. An exterminator or insecticide is defined as any substance, not a fumigant, under whatever name known, used for the destruction or control of insects, vermin, rodents, or other pests.

The Sanitary Code prohibits anyone from using a fumigant, exterminator or insecticide in any building, vessel, or other place, or engaging in the business of fumigation or extermination without a permit from the Board of Health; except that a person may use an exterminator or insecticide in his own home or place of business if food to be sold is not kept on the premises.

Five types of permits are granted by the Board of Health:

1. Fumigant Permit—to conduct the business of fumigation
2. Exterminator Permit—to conduct the business of extermination
3. Employee—fumigant operator permit
4. Employee-exterminator operator permit
5. Owner-operator permit (fumigant or exterminator)

Employers or employees holding permits to do fumigating may also do exterminating, but those holding permits to do exterminating are limited to extermination. Holders of employee permits are allowed to perform fumigation or extermination only while in the employ of the holder of the appropriate permit.

Exception certificates are granted to concerns whose business requires fumigation of its own merchandise or that of others stored in a public warehouse. Such permits authorize them to do fumigation, provided that the exception certificate is first obtained and that the fumigation is performed by the holder of an employee-fumigant operator permit.

Employees who have received apprentice certificates are allowed to assist a fumigator or exterminator operator. Applications for these certificates must be filed by the employer and signed by

him and the apprentice. Apprentices are not allowed to do any fumigating or exterminating except under the direction and supervision of a licensed operator. An apprentice to a fumigator or exterminator, after 90 days of proper service, is eligible to take the employee-operator examination. If the apprentice has had 2 years of academic training, including a course in chemistry, he may take the examination after only 30 days of apprenticeship.

Applicants are examined by the Fumigant Board as to character, training, experience, and fitness. This board consists of 3 employees of the Department of Health appointed by the Commissioner. In the case of a partnership or corporation applying for a permit to conduct the business of fumigation or extermination, at least one member of the partnership or one officer of the corporation must pass the examination for the owner-operator permit. High standards are set for the written examinations, which all applicants must pass.

The Sanitary Code requires that each container of an exterminator or insecticide shall bear a label with the word "POISON" and the symbol of the skull and crossbones in red ink followed with the words "CAUTION"—This exterminator or insecticide contains (state name of poison) a deadly poison," together with the antidote therefor and the name and address of the manufacturer or packer.

The use of poisonous exterminators or insecticides in food establishments is prohibited, although fluoride which must be colored Nile blue at all times may be used where it cannot come in contact with exposed food. Sodium fluoride is a white powder and has in the past been used by mistake for flour, sugar, etc., causing poisoning and in some cases resulting in death. To prevent this, the Sanitary Code of the city prohibits the use of fluoride

unless it is colored Nile blue. Exterminators or insecticides containing living bacterial organisms are prohibited.

Concerns performing fumigation must notify the borough offices of the Sanitary Bureau and the Fire and Police Departments, in writing, 48 hours in advance, giving the location, character, and use of the place to be fumigated, the fumigant to be used and the date and time of the fumigation. They shall also warn all occupants of the place to be fumigated 12 hours in advance, stating the premises to be fumigated, the date and time, the name and address of the concern, the name of its operator, and that the premises must be vacated one-half hour before fumigation is to commence and not reentered until the fumigator posts in the entrance hall a signed and dated certificate declaring the premises safe for human occupancy.

The Code requires the operator to verify that no human beings have remained in the premises to be fumigated; to take all necessary precautions to safeguard the lives and health of persons in adjoining places; and to seal all cracks, crevices, openings and apertures in the walls, ceilings, and floors of the place to be fumigated. He shall post on all doors and entrances to the premises to be fumigated suitable warning signs as follows:

DANGER		
{ Crossbones and Skull }	FUMIGATED WITH (State name of chemical or gas)	{ Crossbones and Skull }
DEADLY POISON		
ALL PERSONS ARE WARNED TO KEEP AWAY		
Name of Fumigator		
Address		
Operator in charge		

The operator must not place the fumigating materials and apparatus in the place to be fumigated until all openings, except that for his entry and exit, have been sealed. While placing and

liberating the fumigant chemicals, he must protect and safeguard himself by suitable gloves and a mask and canister stamped with the approval of the U. S. Bureau of Mines. After he enters to use the chemicals he shall not allow any person other than a licensed fumigator or apprentice to be present until the premises are ventilated and declared safe for human occupancy. Watchmen shall be placed on guard at each entrance to keep people out.

No fumigated place shall be declared safe for human occupancy until the fumigator has

(a) Inspected without gas mask every part of the premises

(b) Kept all windows (top and bottom), doors, and other means of ventilation open for at least 6 hours

(c) Kept all drawers, closets, etc., open for at least 6 hours.

(d) Aired all mattresses, bedding, pillows, blankets, and clothing

(e) Certified as result of final inspection that the entire premises are safe for human occupancy.

Special rooms, vaults, and tanks for fumigating purposes must be approved by the Fumigant Board as to construction, location, and ventilation. These enclosures must be gastight, tested, and inspected periodically. Each door must have a suitable "Danger" sign.

No person shall use in fumigation, nor sell, offer for sale, give away or supply, for use in connection with fumigation, any gas mask and/or canister therefor, unless such gas mask and canister are of a type approved by the U. S. Bureau of Mines, and bear the stamp of approval of said bureau. No person shall refill any canister for use in connection with fumigation after said canister has been exhausted nor use a refilled canister in fumigation. Provided, that this provision in so far as it relates to approved canisters shall not apply if there are no canisters approved by the Bureau of Mines for the gas to be used.

FUMIGANTS, EXTERMINATORS AND INSECTICIDES

Hydrocyanic acid, chloropicrin ethylene oxide, carbon dioxide, methyl formate-carbon dioxide, ethylene oxide, ethylene dichloride-carbon tetrachloride, carbon disulphide, carbon tetrachloride and sulphur dioxide are some of the fumigants which are used to control and destroy insects and other pests infesting buildings and vessels. These are more or less poisonous to man as well as toxic to pests. The last one—sulphur—is cheap and was once a popular household fumigant. It is, however, much less effective than hydrocyanic acid which in the form of a gas is the most effective fumigant now known.

Sodium fluoride, naphthalene, paradichlorobenzene, borax, and pyrethrum are exterminators or insecticides generally used to eradicate and control insects commonly found in households, food establishments, and other places where a food supply is available. Of these sodium fluoride, a fine white powder, poisonous to man, is the most effective and forms the base of many commercial insect powders. Because of its poisonous nature and its resemblance to flour and powdered sugar, it may not be used in New York City unless *colored Nile blue* to avoid confusion with foods or other substances.

It might be interesting to note that physicians who devote their practice to disease due to allergy have many cases due to the allergic conditions caused by pyrethrum. There are a number of holders of exterminator permits who refuse to use pyrethrum because of its effect upon the respiratory tract.

SPECIAL FUMIGATION PROBLEMS

In connection with two new housing developments in Harlem and

Williamsburg Sections of New York City, all furniture and clothing were fumigated with HCN in a separate frame building before they were moved to the new apartments. The advice of public health authorities must be followed on this problem which is one of the important phases in housing.

For the prevention of the spread of disease by rats, the elimination of rat harborages in buildings, vessels, and other places providing food and shelter for these pests, is of prime importance. Fumigation will destroy rats which have found lodging in such places. However, the construction of buildings and vessels in such a way that such rodents cannot gain access, and the maintenance of conditions of cleanliness are the surest and most permanent methods of preventing infestation by rats. Our Sanitary inspectors are required whenever making inspections to look for rat harborages.

The possible spread of disease carrying pests by means of aeroplanes is receiving the attention of public health officials. The Pan-American Airway System now vaccinates all of its flying personnel at various points and in addition has its aeroplanes fumigated on the night prior to embarkation.

CONCLUSION

This paper outlines briefly the importance of the supervision of fumigation and extermination by public health authorities. Adequate training of those engaged in this industry and intensive supervision of this work by health officials, as practised in New York City, are vital if the public health is to be safeguarded.

It is recommended that further studies be made of the relative effectiveness of the various gases and chemicals used in fumigation and extermination.

Heart Disease in Childhood*

T. DUCKETT JONES, M.D.

Research Director, House of the Good Samaritan †; Instructor in Medicine, Harvard Medical School, Assistant in Medicine, Massachusetts General Hospital, Boston, Mass.

IN presenting to this association a few of the aspects of heart disease in childhood one becomes acutely aware of the many gaps which at present exist in our knowledge. In addition, the allotted time is insufficient to discuss many of the pertinent features of this problem in detail. It seems advisable to present a plea for the early recognition of the disease which is the common cause of heart disease in childhood, to discuss certain pertinent features of the disease, and to review briefly what results one may expect from the intelligent care of such children. Since congenital heart disease represents a relatively small percentage of children with heart disease it will not be considered in this discussion.

It is rheumatic fever and the concomitant rheumatic heart disease which is of particular interest because of its prevalence, and the frequency with which it results in a fatal outcome, or some degree of permanent heart damage. It is incorrect to speak of rheumatic heart disease as a complication of rheumatic fever, since the characteristic pathological lesions are found in the heart as well as elsewhere. Not

all rheumatic fever patients have evident heart disease, but it is likely that some degree of heart involvement generally occurs. Fully 90 per cent or more of all heart disease in childhood is of this type, and the problem is indeed a common one in the urban populations of the northern latitudes of our country. Various estimates have been established of the incidence in children of school age as being from 0.5 to 4.5 per cent, depending upon locality. These studies are helpful in determining the magnitude of the problem, but relatively few have been performed with sufficient care to be of appreciable statistical value.

With but few exceptions rheumatic fever and heart disease have never been made reportable and, indeed, the very nature of the disease offers sufficient obstacle to question the value of information obtained by routine compulsory notification. In a small, carefully followed series we have obtained such divergent reports from some physicians as to indicate that material so gathered might be misleading. Despite this lack of actual statistical information concerning rheumatic fever and rheumatic heart disease, there are few physicians, public health workers, nurses, and even school teachers in the urban populations of the northern part of the United States whose attention has not been forcibly di-

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

† Studies in rheumatic fever and chorea in this institution are made possible by a grant from The Commonwealth Fund.

rected to the seriousness of this problem. This is especially true of those who have worked in children's or general hospitals.

It is well to admit at least 3 stumbling blocks when the disease is seriously considered: (1) the etiology of rheumatic fever is unknown; (2) it is probable that the disease has never been experimentally reproduced; (3) no specific therapeutic measures are available. Some would doubtless question the validity of these statements. There has been much suggestive and valuable work, but critical interpretation and analysis of the large volume of literature forces one to these rather distressing conclusions.

It is evident that further knowledge must be forthcoming before effective public health measures may be applied. The problem, however, is one of considerable importance with regard to health of the public, and certain features are sufficiently well established to warrant discussion. Of particular note are a few of the unusual features of the life cycle of rheumatic fever. Further, it is valuable to ascertain just what results may be accomplished in the care of children with rheumatic fever and heart disease. Since any discussion of these questions involves our present knowledge of the cause of the disease, it would be wise perhaps to allude quickly to the various suggestions of a possible causative mechanism.

Since about 1900 the most numerous claims have been with regard to the streptococcus etiology of rheumatic fever. Various means have been suggested whereby some form of streptococcus is supposed to cause the disease. The suggestions may be outlined as follows: (1) The disease is the result of a generalized bacteremia with a specific streptococcus; (2) rheumatic fever is caused by the toxin of a specific streptococcus; (3) rheumatic fever is an allergic disease, the result of the

development of hypersensitivity to the products of various types of streptococci; (4) the cause of rheumatic fever is in some way related to the immunological response of the patient to infection with toxin producing and streptolysin producing strains of the hemolytic streptococcus; (5) rheumatic fever is the result of sub-clinical or chronic scurvy with a superimposed streptococcus infection.

A detailed review of the above hypotheses would be time consuming and is impossible. For a variety of reasons it is necessary to express skepticism as to the validity of these claims. Reference has already been made to the effect that rheumatic fever has not been experimentally reproduced in animals. However, one of these 5 theories deserves further discussion. Recently Coburn¹ has collected a large mass of valuable data concerning the natural history of rheumatic fever and its association with hemolytic streptococcus infection. This author believes that infection with certain strains of hemolytic streptococci followed by an immunological response, particularly as demonstrated by a rise in antistreptolysin titer, is of importance in initiating rheumatic fever. In a large, carefully controlled series of studies now in the process of evaluation and preparation for publication, we have in a large measure substantiated the work of Coburn, but consider that the association between hemolytic streptococcus infection and rheumatic fever is not necessarily one of cause and effect. Infection with the hemolytic streptococcus and the subsequent immunological response may be merely a secondary factor precipitating the clinical manifestations of the disease.

In opposition to Coburn, Wilson and her coworkers² state that neither infection with the hemolytic streptococcus nor respiratory infection in general has any distinct relation to the

onset of the manifestations of rheumatic fever. The time honored association between sore throat (either tonsillitis or pharyngitis) and rheumatic fever is known to most students of the disease. Regardless of what one considers likely with regard to the etiology of rheumatic fever, this association seems likely to hold. When the cause actually becomes established such a feature will have some place, at least in the explanation of the life cycle of the disease. Such infections have a hemolytic streptococcus factor in a high percentage of instances. In observations on some 749 rheumatic fever subjects with regard to the association between the onset of rheumatic fever and various preceding events, 58.3 per cent of 576 rheumatic fever recurrences followed sore throats or colds. In others there developed a definite hemolytic streptococcus immune response indicating a silent infection with this organism. It is also well known from our work and that of others that a recurrence of rheumatic fever follows fully 50 per cent of the sore throats in rheumatic fever subjects. Hence, this type of infection is of considerable importance with regard to the clinical manifestations of rheumatic fever and the progress of the disease in the individual patient.

Further suggestions concerning etiology have been numerous, and two of these warrant short discussion. It has long been suggested that rheumatic fever is caused by a filterable virus. In 1935, Schlesinger, Signy, and Amies³ reported the finding of small bodies by high-speed centrifugation of the pericardial and pleural exudates of rheumatic fever patients. These bodies were visible by darkfield illumination and were reported to be specifically agglutinated by serum from rheumatic fever patients. They were considered to be similar to the so-called elementary bodies proved to be of significance in

such well known virus diseases as vaccinia, psittacosis, ectromelia, and the various animal poxes. More recently, Eagles and his coworkers⁴ have corroborated and extended this work. They have found apparently similar bodies in materials collected not only from rheumatic fever and chorea patients, but also from those with rheumatoid arthritis. In corroboration of agglutination phases of the work, these observers point in addition to an indication of cross-agglutination between rheumatic fever and rheumatoid arthritis. Both of these reports are from the Lister Institute. Bodies appearing to be similar to those described have been easily obtained by high-speed centrifugation, but corroboration of the specific agglutination reactions yet remains to be demonstrated. It is disappointing that successful animal experimentation as the result of these reports has not yet been forthcoming. Such reports are of extreme interest and may prove to be of considerable importance, but further confirmation and successful animal experimentation will be necessary before it can be accepted as proved beyond question.

More recently, Wilson and Schweitzer⁵ have published an extensive statistical report on 112 rheumatic fever families concerning environment, communicability, and heredity of rheumatic fever. This work stresses strongly that there is a hereditary factor distributed among the population which makes the bearer susceptible. Data are given which the authors believe indicate that this factor is transmitted as a single autosomal recessive gene. From the data presented, environment and contagion in the acquisition of the disease could not be evaluated beyond question, nor did the authors state that heredity is the sole condition essential for the development of the disease.⁶ They do state that hereditary susceptibility would seem to determine

familial incidence of rheumatic fever. This familial incidence has been long recognized, and in fact is as high as that of tuberculosis. Such a report as that of Wilson and Schweitzer should stimulate considerable interest and widen the scope of further investigations.

It may be well to discuss briefly contagion, since a high familial incidence has often been considered to be the result of communicability. Paul and Salinger⁶ have pointed out that rheumatic fever spreads from one member of the household to another during or in association with respiratory infections. This was a carefully conceived and executed work. In our series, we have more than suggestive data in corroboration of the findings of these workers. Wilson and Schweitzer believe that if rheumatic fever is spread in families by contagion, the acquisition of the disease is primarily determined by some factor other than exposure to a rheumatic individual. This factor is suggested to be hereditary susceptibility. Rheumatic fever and heart disease have never been classified definitely as communicable diseases but the work of Paul is suggestive. Confirmation of these factors must await the demonstration of the cause of the disease.

Rheumatic fever in an acute form is generally easily recognized, as is also congestive heart failure in patients with rheumatic heart disease and rheumatic fever. In presenting a plea for the early recognition of rheumatic fever and rheumatic heart disease, several pertinent features may be briefly reviewed. Some of these features are not generally appreciated, and all are important in understanding the problem which any child with rheumatic fever or rheumatic heart disease presents.

Chronicity of rheumatic fever—an all feature has been stressed by

Swift.⁷ Save for those who have spent some years in the study of the disease, it is poorly recognized. It is rare in childhood for all evidence of rheumatic fever to subside within several weeks of the onset of the acute phase of the disease. The process is more often of months' duration, and in some, it persists for years. In many children who ultimately succumb, the disease apparently never becomes inactive. The symptoms and signs may be mild and very low-grade, but they are significant. Such symptoms may be briefly mentioned as varied degrees of joint pain, low-grade fever, subcutaneous rheumatic nodules, erythema marginata, frequent non-traumatic nosebleeds, abdominal or precordial pain, loss of weight, or even failure to gain weight, etc. Sydenham's chorea has long been considered to be associated with rheumatic fever, and the association is indeed close. There is evidence that chorea, without other manifestations of rheumatic fever, is not especially conducive to the development of rheumatic heart disease. The chronicity of chorea is well known. Congestive heart failure in the child with rheumatic heart disease should be considered evidence in itself of active rheumatic fever.

2. *Sub-clinical rheumatic fever*—

With the cessation of the clinical manifestations of rheumatic fever, the disease does not become at once inactive. There is usually laboratory evidence of the continuation of the active process. This persists for varying lengths of time, from 2 or 3 months to several years. Laboratory tests of value in this regard are an increase in the sedimentation rate of the red blood cells, repeatedly elevated leukocyte counts, and prolongation of conduction time by electrocardiogram. There is pathological evidence which supports the contention of the continuity of active

rheumatic fever in a sub-clinical form, as indicated by these tests.

The importance of such a phase of the disease is obvious. It explains the apparent silent development of or increase in the degree of rheumatic heart disease. Also it makes understandable the ease with which clinical manifestations appear. Intelligent clinical care of the patient is to some extent dependent upon the recognition of this sub-clinical phase of rheumatic fever.

3. *Recurrences or recrudescences of rheumatic fever*—Rheumatic fever is a recurring disease. It is unusual in the childhood form of the disease for the patient to have only a single illness. The severity of the individual recurrences is to a large extent the determining prognostic feature. Especially important with regard to recurrences is the first 5 or 6 years from the onset of rheumatic fever. In this time, the disease most often recurs. The majority of rheumatic fever subjects who fail to develop considerable cardiac damage, especially cardiac hypertrophy, during this time have a good prognosis.

There is no evidence available which indicates definitely whether or not recurrences are an expression of re-infection.

4. *The importance of events*—Certain events have been noted which seem to influence the onset of the clinical manifestations of rheumatic fever. These are often associated with upper respiratory infections. Usually, rheumatic fever develops within 1 to 3 weeks after such an event, there being at times a so-called silent period. One is familiar with the frequency of recurrences of rheumatic fever following such a procedure as tonsillectomy. Other operative procedures, accidents (such as broken bones), severe sunburn, extraction of teeth, and a variety of minor non-streptococcal illnesses have been observed to precipitate rheumatic fever. Bland and Jones⁸ have called attention to these, as well as to

recurrences following single doses of typhoid-paratyphoid vaccine intravenously (non-specific protein shock therapy). These events play a very definite rôle in the life-cycle of rheumatic fever, though probably secondary to other factors.

The frequency with which respiratory infections are precipitating events in rheumatic fever brings to our attention some of the disadvantages of the present attitude of school authorities. We have been impressed with the school-room as the common source of respiratory infections. It has taken long, persistent education of authorities, teachers, and even physicians to obtain coöperation in an attempt to curtail the exposure of rheumatic fever subjects to respiratory infection. The serious and varied complications of respiratory infection in public and private schools offer a distinct challenge to the medical profession.

5. *Evaluation of the presence or absence of active rheumatic fever*—This is perhaps the most important feature to be determined in the clinical care of the patient with rheumatic heart disease or previous rheumatic fever. Too long has medical attention been directed to an evaluation of the degree of rheumatic heart disease present or an interpretation of various cardiac murmurs. Clinical symptoms and laboratory tests indicative of the presence of active rheumatic fever have been minimized. It is important to recognize even sub-clinical rheumatic fever, since such patients are prone to recurrences of the disease and must be protected from various events and given rest therapy at this time. It is the active disease, rheumatic fever, which is responsible for the fatal outcome in children and young adults. Fully 80 per cent of the deaths we have observed result from rheumatic fever—Bland and Jones.⁹ Hence more attention must be focussed on the evaluation of this process.

6. *The value of rest*—Since no specific therapeutic measures exist we must turn to one of the most generally used laws of nature and physiology for our most valuable agent. There are no adequate data which prove that rest will either prevent the development of or increase in rheumatic heart disease, though there is a general impression among students of the disease that it is of material value. It is probable that rest should be continued so long as there is any evidence of active rheumatic fever. If for no other reason, rest tends to minimize the occurrence of events which often heighten the symptoms. The chronicity and the advisable long period of rest, render the treatment of the child with rheumatic fever a difficult problem.

RESULTS OF FOLLOW-UP STUDIES

Since 1921 the House of the Good Samaritan in Boston has been caring for a large number of patients with rheumatic fever, chorea, and rheumatic heart disease. Some 1,500 children and young adults have been given long hospitalization during this time. The most important single measure in the type of treatment has been rest during active rheumatic infection. An attempt has been made to educate the patient and family with regard to the features of the disease which have been stressed.

So far as possible in subsequent examinations we have attempted to determine the presence or absence of active rheumatic fever at each visit. Not all of these patients came to our attention in an early phase, but the series represents a fairly accurate picture of the disease as seen in childhood.

The follow-up studies presented are relative to the first 1,000 patients, observed for an average period of 10 years from the onset. The average age of onset was 8 years, and the average age at the time of the last observation was 18 years. Hence the data rep-

resent the first decade of rheumatic fever. Upon discharge from the House of the Good Samaritan, 672 of the 1,000 cases had evidence on physical examination of rheumatic heart disease; 328 had no evidence of rheumatic heart disease, and are classified as potential rheumatic heart disease subjects. It is interesting to note the variations which have developed in this group during the 10 year period. Of the 328 patients without evident rheumatic heart disease, 251 are still free from any evidence on examination (7 of this group have died of causes other than those associated with heart disease); 71 have developed some degree of rheumatic heart disease (5 are now dead). Reliable data are not available on 6. Of those patients developing rheumatic heart disease during the 10 years, about one-half did so as the result of recognized rheumatic fever, the remaining half having developed it silently. Of the 672 patients with rheumatic heart disease at the time of their discharge, 230 (34 per cent) are dead. The status of 188 (28 per cent) remained unchanged. In 120 instances (18 per cent) there has been definite evidence of a progression of rheumatic heart disease. In 119 (18 per cent) there has been an evident improvement in the signs of rheumatic heart disease. In 53 of these patients, the physical signs have regressed, while in 66 all evidence of heart disease on physical examination has disappeared. On 15 patients (2 per cent) we were unable to obtain adequate data with regard to the progress of their disease. The present status of the entire group is as follows: 242 are dead; 310 are potential rheumatic heart disease subjects; 427 have definite rheumatic heart disease, while on 21 data are insufficient. Of the 427 patients having rheumatic heart disease and alive, there is no limitation of physical activity in 287, while in 119 the limitation is

moderate, and in only 21 is there a serious physical handicap. It is encouraging to know that in this large group of patients, 597, nearly 60 per cent are able to carry on a normal physical life 10 years after the onset of their disease, and the number with severe limitation of physical activity is indeed small. This lends considerable encouragement to those interested in the care of rheumatic fever subjects and points definitely to the fact that it is a disease in which one may expect good results in a considerable number of instances. The distressing mortality rate of 24.2 per cent should make us double our efforts to add additional information concerning this prevalent disease.

In conclusion, it is evident that public health measures are at present sharply limited because of lack of knowledge. A plea is presented for the early recognition of rheumatic fever and rheumatic heart disease in childhood. The problem is large and difficult, but with early recognition excellent results may be obtained in a large percentage of cases. In an encouraging percentage, clinical evidence of rheumatic heart disease regresses and even disappears. The majority are able to lead an active physical life 10 years after the onset of the disease.

Education of the child and parents with regard to the features of rheumatic

fever and heart disease stressed above, is helpful in obtaining results. Each patient should receive competent medical attention by men as well trained as the group of workers in the field of tuberculosis.

Further study and careful observation of children with rheumatic fever and rheumatic heart disease are the only means whereby it will be possible to suggest and perform public health measures capable of solving this problem.

THE CROYDON EPIDEMIC OF TYPHOID FEVER

CROYDON is a suburb of London with a population of 250,000 persons. On October 27, 1937, occurred what was regarded as the first case of an outbreak of typhoid fever in which there were some 297 primary cases and upward of 25 secondary cases, with 43 deaths. There was a local agitation and a widespread press campaign almost unprecedented in the history of epidemics. An inquiry has been going on for several months, and the report is just now available. The seriousness of the outbreak and the concern with which it was regarded officially may be estimated by the fact that Mr. H. L. Murphy, K.C., was appointed by the Minister of Health to preside, with Mr. H. J. F. Gourley and Sir Humphry Rolleston as assessors, while no less than seven lawyers representing the Croydon Division of the British Medical Association and the Medical and Panel Committee, Sanitary Inspectors, Water Officials, Borough Engineer, Medical Officer of Health, Residents' Commission, and Croydon Corporation, were allowed to cross-question and give summarizing speeches. The Medical Officer of Health was legally represented by one of the bodies which exist for the defence of medical practitioners.

It is regrettable that positive proof of the origin of the epidemic has not been given, but the conclusion is that it was caused by the pollution of a chalk well at Addington, water from which was furnished to between 36,000 and 40,000 inhabitants of the Borough. From the end of September and during October, 1937, work was being done on this well, which is 250 feet deep and 10 feet in diameter. From the beginning of the work until October 15, the water was pumped to waste, but from October 16 to November 3, it was pumped into the supply. From September 28 to October 26, a man later found to be a typhoid carrier was employed, and the pollution of the water is charged to him. Curiously enough, during the time when it was most needed, chlorination was not done, and Mr. Murphy sums up by saying, "The infection was due to an unfortunate and rare coincidence of three factors—(a) constructive changes taking place in the well; (b) one of the workmen being a typhoid carrier, and (c) the process of chlorination being in abeyance."

The general situation in regard to the water supply at Croydon strikes us as being somewhat unusual. Mr. Murphy says, "... the organization of the administration of the Borough was such as to lead to 'both misunderstanding and lack of communication between the responsible officers of the corporation in connection with the work.'" It appears from the testimony that the Borough Engineer is directly responsible for the water supply but that his duties include highways, lighting, drainage, housing, and many other matters, so that the care of the water is deputed to an assistant, and in regard to the Croydon outbreak, there apparently was a misunderstanding between the Borough Engineer and this assistant, who was directly responsible for the water works and the sanitary arrangements for the men who were working in the well. Neither the health officer nor the Borough Engineer was informed of the work going on nor of the stoppage of the chlorination. The medical officer is there to advise when wanted; the engineer to look after the water; but the medical officer is not even asked to attend the water committee meetings, does not receive copies of the agenda of the water committee, but gets the printed minutes later.

It was brought out further that there was nothing in the regulations or conditions of appointment of the Health Officer which imposed on him any particular duties or responsibilities to the water supply. Mr. Murphy states, "... the main task of the Medical Officer of Health throughout the epidemic was the provision of accommodation for the sufferers and the treatment necessary to keep down the death-roll as far as possible."

A striking feature of the evidence submitted was a set of documents, the first one December 10, 1927, and running on to November 9, 1936, showing that the Addington well was frequently subject to pollution, sometimes in the absence of *B. coli*, but sometimes with it. The collecting area of this well also seems to have been under suspicion.

One needs to ask at once what lessons this deplorable outbreak has for the water engineer and the health officer. The English are laying great stress on the value of coöperation between the health officer and the local medical practitioners which is recognized in this country also.

The one possible criticism of the Medical Officer of Health at Croydon is that there was a delay of possibly two days in strongly suspecting the water supply, probably because public water supplies are so carefully protected these days—and in this instance were believed by the Health Officer to have been protected as usual, he being in ignorance of the work and stoppage of chlorination—that he wished to exclude other possible sources before suspecting the water. Some English journals say that it may be necessary to ask the Minister of Health for a pronouncement on the subject as to where the duties of the Health Officer in relation to the water supply begin and where they end. It is held correctly that whether the actual samples are taken by members of his staff or not, his opinion as to the frequency of samples is of importance, and every laboratory report should pass through his hands.

It is plain that the health of workmen on such jobs should be looked into, and that proper arrangements be made for the disposal of urine and feces. The regular water works staff did not supply the labor, which was furnished by 18 volunteers from sewer workers. Mr. Murphy refused to accept statements that they were "carefully selected for physical fitness." A bucket was furnished for urine at the place of work and hauled up for emptying. A latrine for defecation

was dug near one of the adits, and the men instructed to use it. No much cruder system could have been devised. All this without the knowledge of the Medical Officer of Health!

Another point noted is that the credit of a health department may depend more on its quickness in the face of an epidemic than on the number and size of its institutions, or of the number of clients it caters to.

HUMAN TUBERCULOSIS OF BOVINE ORIGIN

IN the 36 years which have elapsed since the London Congress on Tuberculosis at which Koch denied the importance of bovine tuberculosis to the human race, and practically denied the transmission of the disease from cattle to man, observations have been going on in many parts of the world, and after much evidence as to the incidence of the disease in man and the types which it assumes, it is safe to say that the question has been settled as far as the fact of transmissibility goes. For years, even those who believed most in the danger of bovine tuberculosis to the human being were inclined to believe that it seldom or never caused pulmonary tuberculosis. However, from England alone there now have been reported an impressive number of such instances to which other countries have added their quota.^{1, 2}

We cite from a series of notes presented to the Permanent Committee of the "Office International d'Hygiene publique" at the October Session, 1936³: For England and Wales the incidence of human tuberculosis due to the bovine bacillus for all ages is as follows: cervical gland 50, lupus 48.1, scrofuloderma 35.6, bones and joints 19.5, genitourinary 17.4, meningitis 24.3, pulmonary 1.4. For Scotland alone the incidence is higher all along the line without regard to age, though the figures are not strictly comparable: pulmonary 4.59, meningitis 25.8, cervical 65.7, abdominal 80.7, genitourinary 27.7, bones and joints 28.7, gastric lavages (infants) 38.0, tracheobronchial glands 24.0, miscellaneous 9.3. Observations prove what has long been known, that most of the infection is due to drinking the milk of tuberculous cattle; consequently, the highest incidence of the bovine disease is in infants and children.

The Cattle Diseases Committee in England, in 1904, states that not less than 5 cows in every 1,000 were giving milk containing bovine tubercle bacilli. It was found that 13.14 per cent of farmers supplying milk to the City of Manchester were serving milk containing tubercle bacilli. A somewhat unexpected finding is that in Scotland the incidence is higher in rural than in urban areas, doubtless due to the fact that the milk of cities is better protected and that there is more pasteurization than for rural areas. In spite of these findings one will remember a short time ago an effort to improve the milk supply of Manchester failed.

Culture tests in the Low Countries yielded 13 bovine strains in 204 samples of sputum and the same worker found by gastric lavage that 188 infants gave the bovine strain 16 times. Milk samples in this same district showed infection with the tubercle bacillus in from 0.8 to 2.4 per cent, but for cattle slaughtered in the abattoirs, ranged from 34 to 35 per cent of tuberculosis. Tuberculin tests in dairy herds showed from 21 to 40.8 per cent of positive reactors. It is not surprising that all those interested in the production of pure milk and all public

health officials unite in recommending universal pasteurization for market milk. The only wonder is that it is not brought about by universal demand of the consumers.

Lange, of the German Public Health Department, has collected a mass of statistics on the prevalence of human tuberculosis of bovine origin in the various countries of the world, and given them to the Permanent Committee of the Office International d'Hygiene publique. While he has no doubt of the transmissibility of the bovine disease to the human being, he holds that if the bovine bacillus is ever eliminated from man, the diminution of tuberculosis in the countries of the world will not be much diminished and the pulmonary type, which is usually caused by the human type of the tubercle bacillus, will remain the chief source of infection against which preventive measures must be directed.

In this country we are fortunate in having a very strong sentiment among consumers as well as among health officials for the pasteurization of market milk. Unfortunately, statistics showing clearly the influence of pasteurization on the diminution of tuberculosis are not generally available. In New York City there seems to be pretty good evidence that the incidence of tuberculosis in children has fallen since the general introduction of pasteurization. It was noted above that the incidence of human tuberculosis in Scotland due to the bovine bacillus was greater in the country districts than in cities. There is a more or less widespread feeling that this is true in the United States also. We know of only one extensive study which is being made of this question and it is too early to speak positively concerning the results. However, as a whole, the country is on guard against infection from bovine sources, and our Bureau of Animal Industry has done notable work in bringing almost the entire country into the accredited area.

SAFE MILK FOR ENGLAND?

THIS country owes so much to our British friends in the way of hygiene and public health that the situation in England at present regarding pure milk is something of a surprise, if not a shock.

England was one of the first countries to hold a Congress on Tuberculosis at which the question of transmission of the bovine type of organism to human beings was discussed, and fair proof given from America of its occurrence. In spite of this, and in spite of the many great advances which England has made in public health, the attitude in regard to pure milk is still far from what it should be, even on the part of some from whom the public seek enlightenment.

It must be said at once that officially, England is sound on this question, and the great British Medical Association¹ has been laboring for some time to educate the public as to what is meant by "safe milk," with the view of bringing so much pressure on producers and handlers by public opinion that it will be provided. The association recognized that it was not successful through the columns of the newspapers in spreading its doctrines, so decided to offer paid announcements advocating the use of pasteurized milk or that from tuberculin tested cows, which could be alone regarded as safe. Some newspapers and

weeklies accepted the advertisements but others apparently did not. Some published it but questioned the advisability of certain statements, though held that the collective opinion of such an association should not be suppressed because of possible conflict with other interests. One paper said "this unusual reluctance to print an announcement from a responsible advertiser" raised the question as to whether the journals "were influenced by the consideration that the Milk Marketing Board is financially a more important advertiser than the British Medical Association, or whether it was felt that the publication would be contrary to the public interest." Some papers were even more caustic in their comments.

The Lancet in discussing the matter raises the question as to whether or not the pronouncement by the association is scientifically justified. If it is justified, are there disadvantages in using milk which has been subjected to heat? As to the first question, it refers to a report from the Economic Advisory Council, of which Sir Gowland Hopkins was the Chairman, that bovine tuberculosis was responsible in Great Britain for certainly as many as 2,500 deaths each year, in addition to a great deal of serious illness. These figures have never been seriously challenged. The committee gave a list of 103 outbreaks of infectious diseases due to milk, affecting 12,000 people, and stated that these figures are not complete. These general statements are known to the medical profession and familiar to the reading public.

As to the ill effect of heating milk, the exhaustive survey of Sir William Savage is referred to.³ It is acknowledged that vitamin C is destroyed but is pointed out that the content of this vitamin in fresh milk is variable and often small, and that all milk in England requires some vitamin fortification. The effect on diffusible calcium is negligible. The conclusion is reached that the slight changes acknowledged as caused by pasteurization are an insufficient argument to set against the bacteriological safety of the product. The Health Committee of the League of Nations⁴ published a report from a special committee composed of representative men from several nations which gave an authoritative answer to these questions and said that the belief that any alleged injury was done by pasteurization could "be removed to the limbo of disproved and forgotten prejudices."

In the first report of the Advisory Committee on Nutrition,⁵ the opinion is expressed that a largely increased consumption of safe milk would be the greatest single measure toward improving the health of the rising generation. It is recognized that a rise in the consumption of milk which is unsafe bacteriologically would increase the risk from tuberculosis as well as other infectious diseases, a danger which might counterbalance the nutritional benefit, hence the necessity of providing safe milk and of building up public confidence in the supply.

Efforts in a number of cities to require pasteurization and to enable local authorities to prohibit the sale of milk which is not pasteurized or that does not come from tuberculin tested cows, have failed. The B.M.A.¹ believes that local authorities should have power, "after reasonable notice," to prohibit the sale of "milk which is not from tubercle-free herds or has not been submitted to approved treatment to render it bacteriologically safe." The government appears to have accepted this policy.⁶

In Canada⁷ somewhat the same struggle is in progress. In Ontario the government will introduce legislation for required pasteurization of municipal

milk supplies, with apparently a degree of certainty of success. It is backed by the Canadian Public Health Association, which has assembled facts based on the experience of more than 2,000 health officers from coast to coast.

Some of us who were in the early fight for pure milk and the pasteurization of all market milk except "Certified," find it somewhat hard to understand the attitude in such an enlightened country as England, in spite of the fact that it has acknowledged leaders in medicine, preventive medicine, bacteriology, and public health.

THE KING OF ENGLAND RECOGNIZES PREVENTIVE MEDICINE

NEWS comes from England that the King has appointed 6 practitioners of preventive medicine to be honorary physicians to him. The official announcement says that the recipients of this distinction will be drawn "from the members of the medical profession engaged in public health work, both in central and local government." The appointments are made for 3 years.

*The Lancet*¹ voices the gratification felt over these appointments, and points out that from now on the leaders of preventive medicine in England will have the same royal recognition as has for a long time been extended to clinical consultants and senior medical officers in His Majesty's Forces. For a long time it has been felt that the men who have built up the health administration which has been widely copied by other countries, and certainly stands at the top, have been overlooked when honors were accorded. *The Lancet* tenders its congratulations not only to those who have been honored by the King but to the public health services as a whole.

In this country we feel sure that we are safe in expressing sincere gratification over this action of the King. The great public health movement began in England, and we are indebted to that country for many of the best things which characterize our practices in this country.

LETTER TO THE EDITOR

TO THE EDITOR:

The following are comments on a paper by Dr. W. H. Best, Deputy Commissioner of Health, New York City, as published in the *American Journal of Public Health*, October, 1937.

At the time New York City discontinued routine examination of food handlers other than of milk, the City Council of Vancouver was urged to pass a by-law making their examination compulsory. I took the stand that the amount of money required could secure better results in disease prevention by expenditure in other more needed directions. New York's example was a helpful factor in my representation, which was acceded to by the Council.

Since the formation of the Vancouver Metropolitan Health Committee, further pressure was brought to bear on our Council and, inasmuch as our Medical Officer staff was partly available during the school holidays, this work was taken on for restaurant employees, even though we were greatly handicapped by insufficient laboratory service. The success of this work as accomplished in the City of San Diego was an item influencing this decision.

While the compilation of our results was under way, Dr. Best's excellent article came to hand.

Having in mind the need for periodical examination of as many people as possible with a view to the effort to replace cure of disease by more intense efforts toward preservation of health, and disease prevention, and realizing that education of the public and their legislative representatives is a first essential to progress in a democratic country, I feel that examination and education of food handlers has general assets along this line of value, as well

as the finding and control of carriers of disease.

To stress this angle, the following comments are made on the considerations to which Dr. Best has called attention:

1. *Dr. Best:* "The examination of food handlers by private physicians cannot be accepted as reliable."

Comment: Agreed—so that if there is any value to accrue from the examination it should be made by the health department doctors rather than by private physicians.

Dr. Best: "The health department staff, in proportion to the numbers examined, held for observation nearly 18 times as many as the private physicians, and excluded nearly 74 times as many."

Comment: One of every 28 examined was held for observation; 1 in each 452 examined was excluded, as a result of the health department examinations.

2. *Dr. Best:* "The cost is not commensurate with the public health benefits obtained."

"The only ones who might be a health menace through food handling are the typhoid carriers." . . . (Dr. Best then figures the estimated cost of examination at \$130,000 for each typhoid carrier discovered.)

Comments: The cost was less than \$.37 for each one examined. If the health department had examined them all they would, on the same basis, have found as follows:

	Held for Observation	Excluded
Tuberculosis	1,938	119
Venereal Diseases	5,121	442
Typhoid Carriers	4,352	6
Skin Diseases	221	157
Mouth and Throat Infections	(No record)	...
Total	11,632	724

The cost to the city was \$43,000 per annum. They found 2 typhoid carriers; therefore, from the city's findings the cost was \$21,500 each.

If the city had done all the work at an estimated cost of \$100,000 per annum, they

would presumably have found 6 typhoid carriers in place of 2, so that the cost would be \$16,666 for each carrier in place of \$130,000, or about one-eighth of the amount. One typhoid epidemic could cost more than that.

By later epidemiological examination, some 18 typhoid carriers were discovered who were missed by the examinations.

For a carrier to pass on typhoid through the food, he first soils his fingers at the toilet. For each typhoid carrier 20 tuberculosis cases were excluded, and for each one excluded 16 were held for observation. How many of these latter were affected with tuberculosis, but not held because not sputum positive? It has been estimated that the average case of tuberculosis passes it on to 11 more. Tuberculosis positive sputum infests the fingers by contact, and the food by fingers and by coughing, sneezing, and speaking. A daily dose thus acquired is an excellent means for passing on the disease.

Each case of tuberculosis costs the community thousands of dollars. Surely ameliorating this menace is a *public health benefit obtained*. Adding the tuberculosis and typhoid carriers together gives a cost of \$800 per case excluded.

Surely it is worth while from the public health point of view to find cases of venereal disease, even if it is rarely passed on by handling food. The estimate of 442 that might have been excluded makes 567 of the three diseases, lowering the cost to \$176 each. Again adding 157 excludable skin cases gives a total of 724, and would bring the cost per case excludable down from Dr. Best's \$130,000 for each typhoid carrier to \$176 for each excludable case.

By excluding the numerous infections spread from mouth and throat, you bring the cost down to a ridiculously low figure per case.

In addition, there is the value of finding those who otherwise would not know they had anything wrong, or knowing, were not treated by a private physician to remove potential causes of future illness and early death.

Then again, the educational value upon those concerned and the public generally is of inestimable value. Besides the menace of tuberculosis and other diseases in handling food, is their menace elsewhere.

3. & 4. *Dr. Best*: "It is essential to have routine X-ray, Wassermann, and stool examination on all."

Comment: These special examinations might, to lower the cost, be restricted to those only whose carefully taken history or clinical examination suggested the slightest

possibility of infection or contact. Otherwise, if the budget is available it would pay to do first a tuberculin test and X-ray only on the positives, and to confine stool examinations to those who give positive agglutination blood tests only.

5. *Dr. Best*: "Certificates of Health."

Comment: If the cost for school children examinations is all right, why not for food handlers? It is good for the day and, apart from fresh infection, also for the year. The certificate, however, should be given as satisfactory on the day of issue only. Thorough periodical examinations theoretically could prevent 85 per cent of all illness; practically, they have removed up to 68 per cent of all defects in certain trials.

6. *Dr. Best*: "Many communicable diseases are not spread by food."

Comments: Many of the communicable diseases are passed on by exhalations from the mouth and nose, direct to those exposed and also indirect by fomites, of which food is one.

The presence in a community of any communicable disease is an added opportunity of finding carriers. This alone is of value even if spread through the handling of food is limited. Figures are available to show that during a recent influenza epidemic, investigation of the employees in an industry showed that its prevalence among those who ate at restaurants exceeded many times that of those who remained at the plant.

Reporting—Not all cases are reported.

Typhoid Carriers—How can a carrier be reported without finding him?

(a) How about the unseen and unreported cases?

(b) How many carriers arrive from outside the locality?

(c) Those who have been life-long carriers from a case in early life?

(d) From an unrecognized or unrecognized case?

(e) From a person infected but not contracting the disease?

In this section, it is stated that of the 35 carriers found as the result of food handlers' examinations, 23 were found during the period of compulsory examination.

As the result of epidemiological investigation, 28 were found, of whom 18 were discovered during the same period, making a total of 41 carriers who were missed apparently by the private physician examinations—or was their own compulsory examination incomplete?

Relative to typhoid cases cited from 1933 to 1936 with a decrease of 38.6 per cent,

it is fair to note that as it was not till September, 1934, that the examinations were discontinued, the decrease in cases thereafter was only 8.1 per cent, which is coincident with the general country-wide decrease in the last few years. If examinations had been continued and more overlooked carriers found, the decrease would obviously have been still greater. Of course we acknowledge that as the incidence of typhoid fever decreases, the number of carriers goes down too, automatically.

All that is said regarding instruction of food handlers holds good, and this effort should be greatly extended.

Careful consideration given to the facts brought out above certainly seems to warrant asking for reconsideration of the advice that the examination of food handlers is not worth while.

J. W. McINTOSH, B.A., M.B., D.P.H.
Senior Medical Health Officer
Metropolitan Health Committee
Vancouver, British Columbia

April 11th, 1938.

PUBLIC HEALTH EDUCATION*

A Great Year for Health Education—Never has there been such progress in health education in a short period as in 1937-1938.

Ancient taboos as to venereal diseases have been crushed . . . Picture magazines have presented challenging health messages to millions . . . Motion pictures have pictured positive health to greater audiences than ever in the past . . . And maternal care and child birth are becoming decent and respectable.

It all started with a nonspectacular magazine article by the Surgeon General in the *Survey Graphic*. Happily timed, republished in *Reader's Digest*, the article was dynamite for blowing out the key log in a piled up jam of ignorance and neglect. That Dr. Parran was new on the job was in itself a "break." This gave news value to his personality, his background, and his position in the health world. The combination emphasized what he had written. Quickly the opportunity was recognized by many who could make the most of it.

Then came the picture magazines with their millions of new picture-readers. And health benefitted from both technics and circulations far beyond any dreamable health budgets. The picture magazines too have been sound and decent in health presentations. *Look* has had Dr. Morris Fishbein as medical editor, and *Life* has been meticulous in its respect for medical and health standards.

Then came the movies—the March of Time on the screen. This meant exceptional documentary presentations upon more screens than had ever before carried health messages.

We can now look forward to the possibility of nation-wide education as to maternity care. The motion picture, "The Birth of a Baby," is being offered under professional auspices never before granted to a health picture. The 4 page reproduction by *Life* of stills from the picture reached, in one week or so, two million circulation introducing the film throughout the country. The attempts at censorship of both movie and magazine have forced birth and maternal care into public discussion.

Yes, it has been a wonder year for health education.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Nevertheless what happened this year was possible because of what had been done during the preceding years. None of the above listed achievements could have been possible without the foundation work by physicians, health workers, and lay people—hundreds and thousands of them. All honor is due several generations of them.

"Danger Ahead": Steep Hills and Sharp Curves—The spectacular nature of the recent record emphasizes the dangers ahead.

Charlatans already are chiseling on the public interest.

Many would-be friends may need to be curbed.

Those who talk and write for health agencies need to be as wise and careful as ever before.

Public tolerance is not to be overstrained. Public interest is not to be trifled with.

Health educators may well give their best thinking to the opportunity—and the responsibility—which 1937-1938 has brought to them.

"When Ladies Meet"—Under this title is presented "the etiquette of introducing them to the agenda" in an article in *Womans Press*, the Y.W.C.A. official journal, 600 Lexington Ave., New York, N. Y. March, 1938. 20 cents.

Did you ever sit through a meeting in which it was perfectly obvious that not a member present (including the chairman) had had in advance the slightest notion of what matters were to come up for consideration? Minutes ticked by the tens and twenties and thirties while the background, causes, facts and problems were presented. And then the group were expected to discuss, to weigh wisely and to vote without further deliberation. Sometimes after a member got to thinking over the question at home in more leisurely fashion, a fresh idea or possibility occurred to her and she wished that she had voted differently or at least that she had thought of it in time to inject a new angle into the discussion.

Follows a description of how the Oklahoma City Y.W.C.A. sends to board and committee members a variety of mimeographed information sheets covering the business to come before the next meeting. This material is well mimeographed on colored paper, with diagrams and even cartoons when timely.

Even though all members of the group may not read all of the advance material one may be sure that some will, and these informed persons will leaven the whole group with their understanding of the business at hand.

The editor would welcome reports of how health agencies prepare for committee and other administrative and conference sessions.

To Reward or Not To Reward—We have given testimonies against contests and prizes. Here is the other side of the case as stated in *New York State Educator* (April, 1937):

Progressive Education looks with pronounced disfavor upon prizes. Most of us in public school work, however, have inherited situations which compel continuance of certain established prizes whether we like it or not. And anyway I wonder sometimes if P.E. may not be off on the wrong foot in this regard. We try to make school more a real world and less an artificial world, and what do we find in the real world? Great interest, certainly, in the Nobel prize, the Pulitzer prizes, the Newberry prize, the Bok awards, and many others designed to reward good work and stimulate more of it. We applaud the National Speech Arts Fellowship for handing a gold medal to Helen Hayes, some other organization for similarly honoring Ina Claire, and still another for giving the best radio announcer of the year a bit of coveted laurel. The state itself dangles "scholarships" before the eyes of best students in each Assembly District and the whole Civil Service System is essentially a system of conducting competitions with jobs as prizes. Much of normal existence is a valiant struggle for some sort of prize, sometimes winning, many times losing. To know how to win, without arrogance and to lose without discouragement, this is something no school need be ashamed to teach.

IF an accident occurs while your car is traveling under 40 MILES AN HOUR there is only ONE CHANCE IN 44 that someone will be killed....

But—

IF an accident occurs while your car is traveling over 40 MILES AN HOUR there is ONE CHANCE IN 19 that someone will be killed....

DEATH Begins at 40!

A sample page without color from
"Death Begins at 40!"

How It Is Said—For quite a period "Dr. Jones" has been saying things in *Health News*, New York State Dept. of Health. Here is a Feb. 14, 1938, sample:

"Speaking of health information service, I was on a train, here a while ago, going to a meeting and I struck up an acquaintance with a fellow that said he was in the advertising business. I happened to have a copy with me of this 'Drink More Milk' ad we've been running here in the local paper, so I showed it to him. It told how milk is the best food there is, cheap at any reasonable price—and about experiments where a lot of school kids that had extra milk every day—how they gained more weight and height than the others and had better scholarship—and so on. I thought it was pretty good, myself.

"Well, I saw right away he didn't think much of it. He was diplomatic about it: he just read it and handed it back to me. All he said was 'Uh huh.' So I asked him what was wrong about it. 'Well,' he says, 'let me show you.' So he got out a pad and fixed up one himself. It had a sketch

of a stylish looking young lady on it and the stuff he wrote—say!—if you didn't know better you'd think any homely Dumb Dora, if she wanted to be a movie queen, all she'd got to do was drink a quart of milk a day. 'Well,' I said, 'that's a nice looking young lady, all right, but you don't really believe that stuff, do you?' 'Oh,' he says, 'it's more or less true.' And it was: more or less. 'I'll tell you,' he says, 'it's just like commercial advertising. You can't expect to get anywhere,' he says, 'if you stick to facts. You've got to exaggerate a little.'

"I didn't tell him this but it made me think of the old story about the fellow that went into the restaurant with the sign on it—'The Kind of Coffee Mother Used to Make.' He asked the waiter, he says: 'Are you sure this coffee here is the kind mother used to make?' The waiter said it sure was. 'All right,' he says, 'give me tea.' And that's the way I feel about it: if that's 'commercial advertising,' I'll stick to the truth. I may be a little old-fashioned but I figure it's better business—in the long run, anyway.

"Yes, it's awful easy, when you're full of enthusiasm for some new project—it's like putting the biggest apples on the top of the basket—when you're anxious to make a sale, it's a temptation to put all the arguments for it on the top and sort of stick the objections down at the bottom, out of sight. But it don't pay. You don't have to sell a community more'n about one gold brick and the next time you show up you're liable to have the dog set on you before you get past the front gate."

The Hospital (The Clinic) Needs a Bulletin—Florence S. Hyde states the case in "The Hospital Bulletin as a Valuable Educational Medium" in *Hospitals*, American Hospital Assn., 18 E. Division St., Chicago, Ill. Sept., 1937. 50 cents.

Read the article for the reasons why, many of which seem to apply to clinics, sanatoria, and other agencies. The italics below make a good point in department as well as institution organs.

"Regardless of its nature and scope, subject matter published in a hospital bulletin should be non-technical in the main. When it seems desirable to use medical or technical terms their meaning should be made clear in the context. The only place in our Presbyterian Hospital Bulletin in which we use medical

terms without definition is in items quoting topics of addresses given at professional meetings by staff men and those mentioning articles contributed to professional journals.

"The style of presentation both as to copy and layout should strike a popular note while retaining a certain undertone of dignity and seriousness. Headlines should be written with a view of intriguing the interest of the reader in the article or item that follows. Long articles are not desirable and when their use seems unavoidable, sub-heads should be used freely. *It usually is possible to avoid lengthy articles by covering different phases of a subject or describing different activities of a department in several short articles under separate headings.* The plan of featuring a certain department or phase of hospital service in each issue has been followed in the Presbyterian Bulletin and has met with general approval. However, it is essential that adequate space be reserved for current news items about other departments, activities of groups that aid the hospital, affiliated agencies, medical staff, and personnel. An appropriate poem and a bit of pertinent humor should be used now and then."

Then follow consideration of illustrations, news, and case stories. The paragraphs on circulation are particularly interesting, although we may not quote all of them.

"Circulation among patients currently in the hospital is of timely educational value because these people have their minds centered on what the hospital has done or is going to do for them and a few glimpses behind the scenes will make a lasting impression. If informed that copies of previous issues are available, many patients will ask for these and read them with interest. They also will be glad to have extra copies of the current issue to hand or mail to friends who will read them with interest because so-and-so is in that hospital. Members of different groups interested in the hospital can pass along extra copies to their friends who are likely to read the bulletin with especial interest if received in this manner. An issue featuring a certain department or phase of hospital service may be given wide distribution among the members of a special group or organization interested in or whose interest is sought in behalf of that department or service. It is a decided advantage if the bulletin is of a size that will fold suitably and will not increase the amount of first class postage when inclosed with routine letters to former or prospective patients, contributors and others."

Does the above suggest similar use among clinic patients? Especially interesting is the following:

"Obviously the hospital bulletin is distributed regularly to all members of the medical and nursing staffs, and all other hospital personnel, including housekeeping and kitchen help. Many of the benefits of a business house organ accrue from this distribution and in larger hospitals the bulletin creates a better understanding of the hospital as a whole among employees who know little about what happens outside of their respective departments."

We wish that some one would read the entire article and write something of the same nature on the organ or bulletin of a city health department.

A University Anti-Syphilis Campaign—"The Daily Texan Vs. Syphilis," is a reproduction of articles which appeared in *Daily Texan* on the campus of University of Texas. A foreword says:

The Texan articles are arranged chronologically to show the step-by-step development of the syphilis campaign.

Ed Syers, Editor of the *Texan*, supervised the campaign in its entirety. The State Health Department cooperated with Mr. Syers in research, in preparation of the articles and editorials, and in providing speakers for the three anti-syphilis mass meetings held on the campus.

This pamphlet is being sent you so that you may use the material locally for news stories and health talks. I feel that in the following pages you will find the answer to your questions regarding syphilis, and, if you will use these suggestions, you, too, can arouse interest in a syphilis campaign in your county and city.

Then follows the day by day articles, Jan. 13, 1938, through Feb. 11—under headlines, such as:

Regents To Get
Results of Vote
Students' Assembly
Requests Tests

The series includes statements by health authorities, the Governor of Texas, and the University president;

reports of movie showings and campus discussions, together with numerous photographs and diagrams.

About the reproductions, says Dr. George W. Cox, State Health Officer, State Board of Health, Austin:

These articles are reproduced by multi-lithing. This equipment is owned and operated by this department. You will note in the foreword why we have reproduced all of these articles, and I feel that it is a real contribution to the campaign against syphilis. Additional copies can be secured by your readers upon request.

So "Popular" Science Literature
—Hugh H. Darby, in *Nation*, 20 Vesey St., New York, N. Y., closes a review of "Man, Bread and Destiny," as follows:

The increasing amount of space given to science in our newspapers and periodicals, as well as the frequent use of the word to bolster up advertising claims, has at last impressed some of our less able minds with the demand for "popular" science literature. They approach the job with little writing ability, less knowledge of their subject, and a minimum of comprehension of the basic principles of the scientific method. It is one thing to simplify a concept so that readers without technical knowledge can grasp it; it is another thing to distort for dramatic effect. Able writing in any scientific field must come from men with knowledge of the fundamentals of their subject and a willingness to say that here and there science has not yet explored and that we do not know. It would be a great tragedy if the scientific discipline which has led us so far in the past hundred years were to be debased and discarded, as it well might be, through the abuse of the word "scientific" and the popularization of exaggerated discoveries by those who do not comprehend them."

Staff members as well as executives might help a lot to stem the flow of inaccuracy and exaggeration by a little letter writing. Many such misrepresentations are due more to carelessness than to intentional misstatement. Writers, as well as editors and book publishers need to be put on their guard. If they learn that readers resent such writing,

and that interested citizens are likely to protest publication of error and careless statement, surely there will be sounder and truer writing on health topics.

When we learn through a review in the *Journal*, or otherwise, that a book contains errors, let's write to the publisher, to the author if possible, to the editor of our favorite book review periodical, and to book review editors of our local newspapers. A single paragraph may serve the purpose.

And when we see a book review which fails to bring out the weaknesses of a book, then is the time for writing a letter to the editor.

An aggressive bombardment will put editors and publishers on their guard. Indeed, in the absence of such reminders it is likely that many editors and publishers will not be conscious of their failures in guarding the interests of the public. A book review is to help readers to evaluate a book in terms of their own interests. In failing to bring out errors or significant omissions, a review fails in its main purpose.

Returning to the quotation above, Mr. Darby is over-kind when he seems to limit exaggerated writing to those "with little writing ability." Unfortunately some of our "best minds" with skillful pens do not hesitate knowingly to overstate and to misstate for the sake of color and effect. These much acclaimed writers are far more dangerous than the lesser mediocre ones.

COMMERCIAL GADGETS

Users of gelatin and liquid process duplicators need not be limited to the narrow range of paper we have known to be offered by some of the equipment makers. At least, "Atlantic Duplicator" makes available a line of attractive colored papers in blue, pink, canary, goldenrod, green, buff, and salmon. Before you dismiss the idea of colored paper send for a sample book.

Then consider whether you might not enlarge your use of the duplicator with such papers available. If they lure you ask for letter-size sheet samples for a test. There is an "Atlantic Mimeo Bond" in the same colors. The joint sample book contains practical "How to Improve" suggestions for handling all three types of duplication. Address: Eastern Mfg. Co., 500 5th Ave., New York, N. Y.

The latest device for office cleanliness is a hand-portable (electric) vacuum or blower cleaner for the typewriter, calculating machines, card files, book shelves, and possibly, in the laboratory. Ideal Commutator Dresser Co., 1221 Park Ave., Sycamore, Ill.

Reports will be welcome on gadgets, equipment of any type found useful or otherwise in the make-up of the publicity office, or in developing any of the technics employed in health education or publicity. This is an angle which has been given too little attention.

MAGAZINE ARTICLES

"The Birth of a Baby." 4 pages of stills from the new motion picture. *Life*, 330 E. 22d St., Chicago, Ill. April 11, 1938.

"Blood Bank Saves Money, Time and Lives at Philadelphia General Hospital." *Life*. Feb. 28, 1938.

"Cooperative Medicine," by Kingsley Roberts, M.D. Wage Earner's Health Assn., and other coöperative projects. *Womans Press*, 600 Lexington Ave., New York, N. Y. April, 1938. 20 cents.

"The Rise of Group Medical Practice," by T. Swann Harding. *Christian Century*, 440 S. Dearborn St., Chicago, Ill. April 6, 1938. 15 cents. Social

gains; advantages to doctors; profits and necessities; the doctor's choice.

BOOKS AND REPORTS

The Conquest of Cholera, America's Greatest Scourge—*By J. S. Chambers, M.D. New York: Macmillan, 1938. 365 pp. Price, \$4.75.*

This book is devoted chiefly to cholera in the United States, though the first chapter, *Heritages of 1832*, gives a very good résumé of the history of medicine from the early ages to the present.

The author gives 1832 as the date of the first invasion of the New World by this dread disease, and 1892 as the final conquest of it as far as America is concerned. The author has derived his material from what is evidently a very careful study not only of official documents in the possession of the government, but also from contemporary newspapers and private records. Incidentally, he gives a very good history of steamboat travel on our great rivers and the part they played in spreading the disease from town to town. Stage coaches, emigrant parties, and individual travelers also played a part in carrying the disease to new areas. A good deal of bacteriology outside of that of the disease under discussion is mixed in. There are graphic accounts of a number of the best known epidemics such as those of 1833, 1866, 1873, etc. The Gold Rush of '49 and its contribution to the spread of the disease is also well described.

The book is well documented and the author has evidently given a great deal of careful investigation to the subject on which he writes. It is a fascinating and often gruesome story, and a real contribution to the history of cholera. One finds it hard to realize the dense ignorance of the cause of

cholera so short a time ago. Miasma loomed large in the minds of the medical profession as well as the laity in those days. As far as we know, it is the most complete history of the disease in this country.

The author speaks of it as an "evening fireside concoction, compounded of an homeopathic dose of medical lore in a generous draught of cholera history as a vehicle." The illustrations are excellent and fairly abundant. A number of them are of the great doctors of those times and the frontispiece is a portrait of Dr. Daniel Drake. The style is fluent and easy so that the book makes excellent reading, entirely apart from its historical value. It can be heartily recommended.

MAYCK P. RAVENEL

Legal Medicine and Toxicology—*By Thomas A. Gonzales, M.D., Morgan Vance, M.D., and Milton Helpert, M.D. New York: Appleton-Century, 1937. 754 pp. Price, \$10.00.*

Out of their extensive experience in the Medical Examiner's Office in New York City, the authors of this monumental work have produced an eminently practical text on the duties and activities of coroners and medical examiners, and the technics employed by them. Thus, in 39 chapters, they discuss identification, autopsies, differentiation of various mortal injuries and types of homicide, sex crimes, blood tests, and the many aspects of toxicology and poisons. The book is illustrated with about 250 excellent, useful, and often gruesome photographs of actual cases selected from the 15,000

that pass through the Medical Examiner's Office in our largest city every year. The book is well printed and has a good index.

This work, which is dedicated to the late Dr. Charles S. Norris, and has a foreword by Dr. Harrison S. Martland, should be of great value to physicians who are concerned officially or professionally with crimes, accidents, violence, and poisons, and it should also be of interest to lawyers, criminologists, and the police. As Dr. Martland says, it is one of the few authoritative works on legal medicine and toxicology in this country. JAMES A. TOBEY

Apes, Men, and Morons — By Earnest Albert Hooton. New York: Putnam, 1937. 307 pp. Price, \$3.00.

This volume is made up largely of "reluctant addresses" given before various organizations and published in scientific as well as lay journals. The introduction is called "Bright Past and Dim Prospect of a Tottering Biped," which brings out the physical disabilities which have come about in man's progress, many of which are recognized by physicians. The chapter, "Apology for Man," is very interesting and not at all flattering to man.

While the entire book is extremely interesting, there are some parts which are particularly valuable to the readers of this *Journal*. In the chapter, "Teeth Through Time," for example, the author holds that "possibly" under the influence of civilization the teeth and mouth have become foci of infection that undermine the entire bodily health of the species. He goes so far as to see in dental disease the cause of degeneration which may ultimately cause the extinction of the human species. While his views are perhaps somewhat extreme, they bear out the increasing interest which hygienists are taking in oral hygiene.

In another chapter, "An Anthro-

pologist Looks at Medicine," the author expresses the belief that the relationships between anthropology and medicine are many and of great value. He recommends an institute for research in applied human biology and believes that norms and variabilities in morphology, physiology, psychology, and neurology should be established, that racial susceptibilities and immunities should be determined, and that the results of the study of human heredity could be applied to medical practice and lay the foundations for a rational science of eugenics.

Some findings are disturbing. Peoples who live on natural food products by fishing, hunting, etc., show the largest number of primitive physical characters, but at the same time the fewest evidences of disease and degenerative evolutionary features. Contact with civilization seems to be always bad. As soon as man shifts to an artificial and agricultural basis of subsistence, physical deterioration seems to set in. While the primitive man does not live as long as we do, he seems to be more free from disease. The biological status of man seems to decline as his culture accelerates. Medical science reduces suffering and prolongs life, but, unfortunately, preserves the malformed, the chronically diseased, and the biologically inferior.

The last chapter sums up what we must do to be saved. The author recognizes that there are many gaps in our knowledge of human biology and that we do not know enough to breed geniuses, but is firm in his opinion that we must bring about a "sit-down reproductive strike of the busy breeders among the morons, criminals, and social ineffectuals of our population." He holds that a biological purge is the essential prerequisite for a social and spiritual salvation. "We must stop trying to cure malignant biological growths with patent sociological

nostrums. The emergency demands a surgical operation."

The book throughout is well worth reading. The author has a sharp tongue and a keen satire. Although the book leaves one with the impression that he is pessimistic over the future, he denies this.

MAZŮCK P. RAVENEL

Bacteriological Atlas—By Richard Muir, enlarged and rewritten by C. E. van Rooyen. (2nd ed.) Baltimore: Wood, 1937. 90 pp., 83 col. pl. Price, \$5.25.

Various improvements have been introduced into the second edition of this much used Atlas, from Edinburgh. By increasing the size of the page slightly, two of the circular colored plates are printed per page so that with an increase in number of plates from 60 to 83 the number of pages is reduced from 134 to 90. By dividing circles into halves, thirds or quadrants, 39 additional figures are shown. Descriptive material is reduced to a minimum as it is expected that the *Atlas* will be used in connection with a textbook.

The color printing is better than in the first edition. Although the plates give an impression of artificiality, they nevertheless, are drawn accurately as to detail and are, as a matter of fact, more satisfactory from the student standpoint than photographs. Dr. van Rooyen, who undertook the work of developing this *Atlas* after the death of Professor Muir has not attempted to give the impression that the drawings were made from preparations examined under a microscope and in his new drawings has utilized the center area only.

In these days when systematic bacteriology is at last making some progress in bringing about an orderly arrangement of the thousands of described species of bacteria, it is unfortunate that the author maintains an ultra conservative position and calls

all rod shaped bacteria *Bacillus* in accordance with the custom popular 50 years ago. Thus, we have *Bacillus coli*, *Bacillus tuberculosis*, *Bacillus diphtheriae*, and the like, in spite of the international action taken by the 2nd (London) International Microbiological Congress, limiting the use of this generic term to spore-forming rods (*J. Bact.*, 33:445, 1937). Some concession is made to modern progress in this field, by inserting commonly used names such as *Escherichia coli*, *Mycobacterium tuberculosis* and *Corynebacterium diphtheriae* in parenthesis. In spite of international acceptance of standardized spellings for scientific names and the fact that the authors who proposed the name *Hemophilus* observed these rules, this name appears as *Haemophilus*. ROBERT S. BREED

Good Housekeeping and Safety in Foundries—Reprint No. 37-30, Management Series No. 1—1937. Chicago: American Foundrymen's Association, Inc. (222 West Adams Street), 1937. 61 pp. Price, \$1.50.

This bulletin contains the proceedings of the 41st Annual Convention Sessions on the subjects in the title and comprises 9 papers: Proceedings of Management Session on Safety and Good Housekeeping; Foot and Leg Protection in the Foundry, by M. W. Dundore, Beloit; The Use of Eye and Respiratory Protection in the Foundry Industry, by John H. Holzbog, Milwaukee; A Consideration of Human Silicosis, by Dr. Norbert Enzer, Milwaukee; Good Housekeeping in the Foundry, by Dr. E. G. Meiter, Employers' Mutual, Wausau; Maintenance of Safeguards in the Foundry, by James Thomson, East Chicago, Indiana; Industrial Codes and Occupational Disease Legislation, by D. M. Avey, Secretary of the Association, Chicago; Industrial Codes and Their Applications, by James R. Allan,

Chicago; and *The Essentials of Occupational Disease Legislation*, by O. E. Mount, Chicago. The Convention was held in Chicago, May 5-6, 1937.

This bulletin, which comprises the ideas and experiences of those actually in the foundry industry or having close contact with it, should be read by all interested in the titles concerned and particularly those interested in silicosis and occupational disease legislation. The articles by Dr. Enzer and Dr. Meiter will be of particular interest to health workers, as each considers especially fundamentals for the bettering of health conditions from the medical economic viewpoint. The bulletin also contains considerable discussion, e.g., by E. B. Kuechle and others on Wisconsin's law (which permits of compensation of non-disabling silicosis), the "dumping" of employees, and labor's viewpoint on medical examinations. EMERY R. HAYHURST

Poisons, Potions and Profits: The Antidote to Radio Advertising—*By Peter Morell. New York: Knight Publishers, Inc., 1937. 327 pp. Price, \$2.00.*

The jacket of this book calls it devastating. There is no question that this is the correct term. It is a pitiless exposition of the false and dangerous claims which are being given to the American public over the radio. It is frankly sickening to read the lists of entertainers, including even the charming Grace Moore, who have lent themselves and their talents to the exploitation of doubtful products and even some which have been found unacceptable and dangerous by competent laboratories and their investigators.

The book ends with what is called a Consumer's Radio Log, some 35 pages, which gives lists of beauty preparations, hand lotions, cigarettes, automobiles, etc., which have been found worthless or dangerous. The

selling price of many of these preparations, especially cosmetics, as related to the costs, is given in tables. What purports to be the New York City Secret Black List of dangerous drugs and cosmetics is given in full.

The book is thoroughly documented and we believe it to be reliable in every respect. In view of the fight which has been going on in Congress for several years and is continuing during the present session, to enact legislation concerning food and drugs which will protect the people financially as well as in regard to their health, this book is especially timely and can be recommended. MAZYCK P. RAVENEL

Biological Laboratory Technique: An Introduction to Research in Embryology, Cytology and Histology—*By J. Brontë Gatenby, Ph.D. (Dubl.), D.Sc. (Lond.). New York: Chemical Publishing Company, 1937. 130 pp. Price, \$3.00.*

While the author of this little volume considers it as "a short and simple introduction to the most recent and established practice in microtomy," he has, nevertheless, written a handbook for the tissue technician. It is amazing how much helpful advice can be packed between the covers of a 130 page book when the style of writing is as concise as that employed by Dr. Gatenby in *Biological Laboratory Technique*. The richness of the author's experience with the various methods of preparing tissues and specimens for study is amply reflected in the pages of this book.

JOSEPH A. KASPER

Reading, Writing and Speech Problems in Children—*By Samuel Torrey Orton, M.D. New York: Norton, 1937. 215 pp. Price, \$2.00.*

This book is a worth while expansion of Dr. Orton's 1925 article in the *Archives of Neurology and Psychiatry*. It should challenge the gen-

eral practitioner and pediatrician to become conversant with the early diagnosis and treatment of speech and writing disorders. With this book as a guide the physician can intelligently instruct the parents whose child presents the problem of left-handedness, baby talk or failure to talk. It should inspire the teacher to a greater acquaintance with the problems of poor writing, spelling, reading, and arithmetic among her pupils. Such an acquaintance would help to reduce the number of "mentally retarded," "nervous," and "incurable" children in the schools. The understanding parent could learn a good deal from the portion of the book in which the author deals with the emotional reactions of these unfortunately misunderstood and neglected children.

Dr. Orton elaborates his subject in a manner which may not at first appeal to a person unfamiliar with or uninterested in neurology. His first chapter deals with "The Language Losses in the Adult as the Key to the Developmental Disorders in Children." This chapter may discourage those who shun precise terminology. However, the author has so simply and logically followed the fundamental patterns described in this chapter that the reader finds the subsequent material expanding and becoming more concise in an effortless fashion. The chapter on the description of the disorders and the final chapter on treatment contribute to clarity by purposeful repetition and summarization.

Educators, physicians in behavior, and mental hygiene clinics, and teachers specializing in speech, writing, and reading disorders, should welcome this much needed book. Directors of nursery schools and preschool centers should be thoroughly familiar with Dr. Orton's views on sidedness and problems relating to changed laterality: it may be in this field that unique pre-

ventive work can be done to reduce the occurrence of these disabilities.

W. F. SCHNEIDER

A Workbook in Health for High School Girls—By Gladys B. Gogle. *New York: Barnes, 1937.* 267 pp. Price, \$1.00.

This workbook presents various health habits for checking, questions to be answered or discussed, and planned problems for which the pupil is to write out the answers.

After many of the units a good bibliography of texts of the proper age level is provided, which enables the teacher to make definite assignments of reading and to develop discussion as a preliminary to written use of the book.

A valuable effort to provide the teacher with a usable procedure.

CHARLES H. KEENE

The Principles and Practice of Clinical Psychiatry — By Morris Braude, M.D. *Philadelphia: Blakiston, 1937.* 382 pp. Price, \$3.50.

Messrs. Blakiston now have two textbooks of clinical psychiatry of the same size and general scope, addressed to the same group of readers. Their earlier text by Strecker and Ebaugh has served and still does admirably serve its purpose. The new text by Braude contains certain differences of emphasis and includes historical references; it relies less upon its case histories which are printed in small type; the bibliographical references are most recent; the literary style is somewhat tiresome and the binding is waterproof.

Health officers are usually more interested in mental hygiene than in clinical psychiatry. But they are sometimes called upon to give evidence in sanity hearings. A chapter on the preparation of evidence for such occasions might perhaps have been fairly included in the textbook under review, since it is addressed to students of the

social sciences and of jurisprudence as well as to students of medicine. No such chapter is to be found.

J. ROSSLYN EARP

Public Health and Hygiene, A Students' Manual—By *Charles Fredrick Bolduan, M.D., and Nils William Bolduan, M.D. (2nd ed.) Philadelphia: Saunders, 1937. 371 pp. Price, \$2.75.*

In the 7 years which have elapsed since the appearance of the first edition and the preparation of the second, many new things which should be incorporated in a book of this sort have come up and the authors have taken advantage of them. This second edition is almost a new work. It has been thoroughly revised, many chapters have been rewritten and 5 new chapters have been added.

It is designed for medical students as a review for their regular courses in public health and hygiene, for college students, graduate nurses, and social service workers. We believe it fulfils the objects for which it is designed in an unusually satisfactory manner, and within its scope it can be highly recommended. The printing and illustrations are good. MAZYCK P. RAVENEL

Principles of Medical Statistics—By *A. Bradford Hill, D.Sc., Ph.D. London: The Lancet, Ltd., 1938. 171 pp. Price, \$2.25.*

This is a balanced, well written book on elementary statistics. It was originally prepared at the invitation of the editor of the London *Lancet*, in the form of a series of short articles for that publication. The book was addressed primarily to the physician, but it will also be found an excellent introduction to statistics for the health worker. Although small, as scientific books go, this book includes discussion of some important subjects frequently omitted or slurred over in statistical texts.

The chapter headings include, among others, selection, presentation, variability and standard deviation, averages, three chapters on sampling including a discussion of chi square, correlation and life tables. One of the most useful features of the book is the 3 chapters, packed with useful advice, on common fallacies and difficulties. Most persons could read these chapters at the outset, and again at the end.

The appendix includes a 2 page table of chi square, and 3 pages of definitions and formulae. A. W. HEDRICH

The Biology of Pneumococcus—By *Benjamin White, Ph.D., with Elliott Stirling Robinson, M.D., Ph.D., and Laverne Almon Barnes, Ph.D. New York: Commonwealth Fund, 1938. 799 pp. Price, \$4.50.*

Pneumococcus is altogether an amazing cell. Tiny in size, simple in structure, frail in make-up, it possesses physiological functions of great variety, performs biochemical feats of extraordinary intricacy and, attacking man, sets up a stormy disease so often fatal that it must be reckoned as one of the foremost causes of human death.

Thus, in two compact sentences, Dr. White justifies an interest in, and a concern over, this microörganism that is sufficient to bring forth a book of the size and scope of *The Biology of Pneumococcus*. In the following paragraphs of his introduction, he points out the rôles played by the sanitarian, pathologist, epidemiologist, physician, bacteriologist, immunologist, and chemist in the battle against the "stormy disease."

The authors have compiled into one volume the results of years of research by the various workers and have given us a complete review of the literature on this subject. The history of research relating to the pneumococcus is described, beginning with its discovery in 1875, continuing on with a discussion of all the work that has been done up

to the present time, and suggesting problems yet to be solved. The bacteriological, biochemical, and immunological characteristics of the organism are dealt with at length. The chemotherapy, vaccine and serum therapy of pneumonia form no small part of the book.

The appendix is a part of the book that every laboratory worker should value. Directions for various laboratory procedures are given: methods for the preparation of media, for the isolation of the pneumococcus, for typing, and for the isolation of the component parts of the pneumococcus. There, too, are given directions for the preparation of antipneumococcus serum, including serological reactions, potency, and sterility tests.

The bibliography includes nearly 1,600 references and embraces practically everything that has been written about the pneumococcus.

The Biology of Pneumococcus is not only an excellent reference book; it makes a very readable story as well. It is a book that only a person of Dr. Benjamin White's type could produce. It reflects his sterling scientific acumen, and capitalizes his extensive experience and his extraordinary capacity for doing a task completely and thoroughly.

WILSON G. SMILLIE

Milestones in Medicine—Introduction by James Alexander Miller, M.D. New York: Appleton-Century, 1938. 276 pp. Price, \$2.00.

This book is made up of the "laity lectures of the New York Academy of Medicine." The Introduction by Dr. Miller, President of the Academy, says that these lectures "are unique in that by an historical presentation of the development of medicine's ideologies, knowledge and techniques, not only the established facts are presented, but also the sequence of and reasons for their evolution."

The book does not lend itself readily to review. Each lecture has been given by a master in that special field to which it is devoted, and each is complete in itself.

Needless to say there is an enormous amount of valuable and interesting material given. We cannot but think that one or two lectures, at least, will make pretty hard reading for the average layman, although the material is as simply and plainly put as is possible considering its content. The book is to be thoroughly commended. The printing and make-up are excellent.

MAZÏCK P. RAVENEL

Toxicology—By William D. McNally, A.B., M.D. Chicago: Industrial Medicine, 540 No. Michigan Ave., 1937. 1022 pp. Price, \$10.00.

A Foreword by Dr. Carey P. McCord emphasizes that civilization may be measured by the number of poisons man has discovered, obviously for his use but seriously to his risk. Toxicology is the branch of medicine which nearest approaches an exact science and, as such, the present book is singularly free from the ancient thralldom of the occult.

The work is intended as a modern text for the medical and legal professions. The subject matter has been the bases of a course of lectures and the sources have included standard texts and reference works as well as original literature. Peterson, Haines, & Webster's *Legal Medicine and Toxicology* is the first mentioned text-authority, Henderson and Haggard's *Noxious Gases*, the next, etc., but other American and foreign texts have been given due cognizance.

General Considerations (58 pages) classifies the poisons, their mode of entry, diagnosis, general treatment, methods of detection, common forensic questions, and post-mortem appearances. *Inorganic Poisoning* (24 pages)

covers the corrosives. *Metals and Non-Metals* (223 pages) goes exhaustively into 28 substances with, of course, much space devoted to lead, mercury, arsenic, and their compounds. *Gaseous Poisons* (145 pages), naturally emphasizes carbon monoxide, nitrogen oxides, and the refrigerants. *Alkaloidal Poisons* (155 pages) includes many of the newer ones, even to tremetol ("milk sickness") and sulphanilamide. *Volatiles, Distillates, and Solvents* (99 pages) includes the petroleum distillates, the alcohols, acetates, aldehydes, and certain chlorinated hydrocarbons such as carbon tetrachloride. *Drugs and Miscellaneous* (167 pages) comprises a long list, including the newer local anesthetics. There follow *Food Poisoning and Food-Borne Infections* (19 pages); *Death from Powdered Glass* (4 pages); the medicolegal aspects of *Blood and Seminal Stains* (57 pages); *Hair and Other Fibers* (73 pages); *X-rays and Other Forms of Radiant Energy*—a special chapter by Hollis E. Potter (6 pages); *Silicosis and Asbestosis*, especially in relation to their determination and methods of collection (13 pages); and a final half-dozen pages devoted to *Radium, Bites and Stings*, and *Wax*.

Turning practically to any page, one gains the impression of much said in a few words, definiteness of statement, and wholesome inclusion of the literature; for example, the 10 pages devoted to *Nitrogen* and its *Oxides*. Fortunately, nearly all references are footnoted on the given page of the text, and numbered consecutively.

Some subjects, like *carbon monoxide*, have a tremendous literature and despite nearly 200 references cited, one can readily think of others which might have been included. The collection of the vast amount of material on such a subject is difficult so that here, as elsewhere, the reader finds much confusion in arrangement, lack of index

facility, and oftentimes is unable to distinguish between citations and the author's own discussions and evaluations. Some typographical errors, lack of desired details, and over-inclusive statements appear.

Under *lead poisoning*, very limited space is given to the acute form (which is probably well conceived) while the author uses the Fairhall method for lead detection, omitting description of the much more sensitive dithizone and spectroscopic methods, the former of which is widely used.

In general, citations can be readily found to serve either side of a medicolegal controversy, but recourse to the original literature cited may often explain why "this is not the same kind of a case."

Sixty-five valuable tables are scattered throughout the text and there are 29 illustrations and 4 colored plates. There is a detailed table of contents, but an all too brief index.

The book is handsomely bound in substantial stiff covers and printed in "excelsiora" type, claimed to be accepted by experts as easiest to read.

Unquestionably it is a leader in the industrial toxicological field and is indispensable to all interested in toxicology and its medicolegal aspects.

EMERY R. HAYHURST

Not So Long Ago—A Chronicle of Medicine and Doctors in Colonial Philadelphia—By Cecil K. Drinker, M.D. *New York: Oxford University Press, 1937. 183 pp. Price, \$3.50.*

This book is founded on the well known diary of Elizabeth Drinker, kept from 1758 until a few days before her death in 1807. The first two chapters describe life in Philadelphia in those early days, whereas most of the others give a good picture of deplorable sanitary conditions, lack of sewerage systems, pure drinking water, etc. One

of the most grotesque yet interesting stories is that of a well which was supposed to have curative properties as mineral water and was widely used, yet turned out to be connected with a cess-pool, which was discovered only when the well was exhausted on account of the quantity of water taken from it. The book is valuable as giving quite intimate pictures of the great medical men of that time, like Benjamin Rush,

William Shippen, John Bard, Adam Kuhn, Philip Syng Physick, and others.

The book is well printed and has most interesting illustrations, chiefly pictures of the great men whose stories are recorded in the diary. As a contribution to colonial history as well as to medical history of that period, it can be highly recommended.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Health Administration and Physical Fitness—Among the things that the British do better than we is taking a subject apart to see what makes it tick. At a council meeting the subject was school health. In the United States, such a meeting would have been given over to statistics of defects found, ways of inducing children to brush their teeth, and other trade practices. Not so there. The discussion turned on national fitness, organized athletics versus hygiene, the condition of the working classes, the true value of the "physical jerks," and a dozen other lively social topics. A good time was had by all.

AXON. *The Health of the School Child*. J. Roy. San. Inst. 1, 6:325 (Mar.), 1938.

Rural Tuberculosis Prevention—Because isolation of open cases is of so much more value where exposure to mass infection is slight, rural health authorities are urged to get busy with a case finding and case supervising campaign. Cattaraugus County has shown the way.

ATWATER, R. M. *The Control of Tuberculosis in Rural Areas*. Canad. Pub. Health J. 29, 2:53 (Feb.), 1938.

Least Expensive Optimal Diets for Babies—Excluding meat from the youngster's diet and keeping fats and sugars low are the principal factors in building up a satisfactory diet at minimum cost. Milk, eggs, vegetables, and fruit are much the same in all diets, though practical economies in the purchase of the last are suggested.

BALL, V. K. *Low Cost Diet in Babyhood*. Pub. Health Nurs. 30, 3:137 (Mar.), 1937.

Early Diagnosis of Measles—In reading this discussion of the differences in the inclusion bodies found in the specimens from nose and throat of patients suffering from measles and those from other diseases, including colds, influenza, and poliomyelitis, one gets the impression that much research lies ahead of the bacteriologists who would come to the aid of the epidemiologist in controlling measles.

BROADHURST, J. *The Early Diagnosis of Measles*. Am. J. Nurs. 38, 3:251 (Mar.), 1938.

More Scarlet Fever Prophylaxis Than You'd Expect—Canvassing 9,000 families in 130 localities, the attacks of scarlet fever, among other conditions, were recorded. A surprisingly large proportion, 4 per cent, of 10 to 11 year old children were reported to have been immunized against the disease. Of 208 cases occurring (during the period under survey) among children under 15 years, 3 were second attacks, and 2 were in immunized children. The remaining 203 children had not been immunized or had not had previous attacks. Statistically these figures may be insignificant, but they are interesting nevertheless.

COLLINS, S. D. *History and Frequency of Clinical Scarlet Fever Cases and of Injections for Artificial Immunization among 9,000 Families, Based on Nation-wide Periodic Canvasses, 1928, 1931*. Pub. Health Rep. 53, 11:409 (Mar. 11), 1938.

Dental Health Attitudes—Beginning with 9 dental untruths certified by the woman's magazine carrying the advertisements, the author discusses the

lack of adequate and authentic dental health education. General dental knowledge is a curious mess of fact, folklore, proprietary and food product advertising, and most school teachers seem to get their information from the same sources. Only 6 truths need be taught.

EASLICK, K. A. Dental Health Education—Can School Children Get It? *J. School Hyg. S.* 3:68 (Mar.), 1938.

Research in Diphtheria Prophylaxis—Sound studies made upon immunity responses to diphtheria prophylactics show a higher degree of immunity when 3 doses of unmodified toxoid are used than when other products were used in any combination. Field studies, too, show a better end result when 3 doses are used instead of 2.

FITZGERALD, J. G., *et al.* Diphtheria—A Preventable Disease. *Lancet.* 1, 7:391 (Feb. 12), 1938.

Bacteriophage Still Tantalizes Research—Although houseflies normally harbor bacteriophage, when reared in a sterile environment, they produced no phage against a susceptible organism fed to them. On the other hand, when fed the phage without the homologous organism, the phage would not persist as it does for many generations when combined with the bacterium. These results indicate that phage is not the result of interaction of bacteria and animal host as has been proposed.

GLASER, R. W. Test of a Theory on the Origin of Bacteriophage. *Am. J. Hyg.* 27, 2:311 (Mar.), 1938.

Teaching Home Safety—Popular ways of meeting the grim reaper in your home are presented realistically. Half the accidental deaths are due to falls, as always. Burns and scalds come next, and make up in suffering what they lack in numerical strength. As

with burns, children are the chief victims of accidental poisoning. Gas and mechanical suffocation and electrical shock continue to add a respectable quota to the holocaust.

MELPOLDER, J. Hazards in the Home. *Pub. Health Nurs.* 30, 3:165 (Mar.), 1938.

White Men's Diseases and Negroes—The 12 million spent to fight syphilis seems like quite a sum until one remembers that 10 million are spent annually to care for the syphilitic blind and 32 for the syphilitic insane. What should be done for both syphilis and tuberculosis in both the white and negro populations is strikingly told.

PARRAN, T. No Defence for Any of Us. *Survey Graphic.* 27, 4:197 (Apr.), 1938.

Dead Men Tell Tales—Calling attention to the fact that Chapin found the relation of sickness incidence and tax paying ability to have been about the same 75 years ago in Providence as the recent nation-wide survey disclosed among our modern poor (the 40 to 50 million American people living upon a family income of less than \$1,000), the author presents all the statistics you will ever need about illness in the latter group. He pleads for better statistical services from welfare agencies.

PERROTT, G. St. J. Health Problems of Low Income Families. *Health Officer.* 2, 10:488 (Feb.), 1938.

"Train Up a Child"—If confession really benefits the soul, this author may now boast a grade A article. Recalling the days when he held that doctors and dentists were proper authorities to "lecture" school children on their health behavior, he recounts his conversion to the belief that teaching should be done by teachers who are properly equipped to teach. A fine Canadian program to meet this situation is outlined.

PHAIR, J. T. An Experiment in Health Teaching in Ontario. *J. School Health,* 8, 3:73 (Mar.), 1938.

A Tooth for Every Child?—No evidence is discovered by this author to establish a correlation between calcium metabolism of the body and dental caries in the adult tooth, nor is proof found of the increased incidence of caries because of metabolic changes during pregnancy. Growing teeth only are affected by calcium disturbance. If these findings are true, health educators will find themselves out upon still another limb.

SCHOUR, I. Calcium Metabolism and Teeth. *J.A.M.A.* 110, 12:870 (Mar. 19), 1938.

Sunlight Injures Pellagrins — Briefly reviewing the high spots in the research upon the cause of pellagra since Goldberger's classic demonstration of the possibility of causing the disease by deficient diet, the place of exposure to the sun in producing symptoms is made clear. Modern treatment methods are also discussed. The history and incidence of the disease are covered in a long editorial in the same publication based upon an address by W. H. Sebrell.

SMITH, D. T. Present Knowledge of Pellagra: Clinical Studies. *J. Am. Dietetic Assoc.* 14, 3:168 (Mar.), 1938.

Two Years of Premarital Tests —During the time Connecticut's premarital law has been in operation, 1 candidate for marriage in each 50 has been found to be syphilitic. In the first year of operation, marriages fell off, but the second year found them on the way back to normal. It is to be hoped that this measured statement will have wide reading by the alarm-viewers and doubting Thomases.

TALBOT, H. P. Results of Premarital Blood Tests—1936 and 1937. *Connecticut Month. Health Bull.* 52, 2:39 (Feb.), 1938.

Revised Technic for Sunshine Measure—Using the principle de-

pendent upon the property of ultra-violet light to decompose certain chemicals in proportion to intensity, a practical apparatus is described and suitable technics are proposed. With it climatic surveys of actinic sunshine may be made in any community.

TONNEY, F. O., and SOMERS, P. P. A Complete, Revised Technic of Actinic Sunshine Analysis, with Modifications for Freezing Weather and Near Meridian Exposures. *Am. J. Hyg.* 27, 2:370 (Mar.), 1938.

How Syphilis Is Treated—Some of many observations on syphilis culled from an exceedingly valuable Chicago survey: 59 per cent of those who acquire syphilis do so before age 30; of patients with a positive blood test at the end of treatment, 3 per cent had a relapse, while of those with a negative test, 4 per cent had relapsed; of the women patients, 11 per cent became pregnant after infection; in half these cases, the infection was not detected until after the 5th month, and of those that were discovered early, only 21 per cent were adequately treated. Does anyone doubt the need of adequate anti-syphilitic measures?

USILTON, L. J., *et al.* Prevalence, Incidence, and Trend of Syphilis in Chicago. *J.A.M.A.* 110, 12:864 (Mar. 19), 1938.

Our First National Public Health Program—What public health protection did the United States obtain from the 8¾ millions appropriated to the states under the terms of the social security act during its first full year of operation? Rural counties showed a net gain of 331 full-time health units, 1,500 individuals received postgraduate training, and the long list of projects undertaken in all the states of the union is an imposing one. But the most inspiring fact is the plan for the future.

WALLER, C. E. A Brief Review of Progress in the Public Health Program. *Health Officer.* 2, 10:472 (Feb.), 1938.

"The Scout"—statue by Cyrus E. Dallin. Skyline of downtown Kansas City in background.

KANSAS CITY INVITES YOU

ALL the world knows Kansas City as the "Heart of America" lying just 9½ hours by air from Los Angeles or 6½ hours from New York. Here at almost the exact geographical center of the United States a network of paved highways and trunk-line railroads converge providing speedy and direct transportation to all principal cities.

Most of Kansas City's leading hotels are compactly located within three blocks of the Municipal Auditorium or the heart of the shopping district.

Kansas City's Municipal Auditorium will serve as convention headquarters of the A.P.H.A., and description here becomes a bit difficult without the use of superlatives. Constructed at a cost of approximately \$6,500,000, the auditorium is one of a trio of recently completed municipal buildings. Though still pungent with the odor of new paint and fresh plaster, the auditorium has proved to be one of the most adaptable convention buildings in the country. By effective use of color and modern indirect lighting it aptly demonstrates the possible combination of beauty and utility in public buildings.

Thirty-two units range in seating capacities from 25 to 14,000 and may

be used separately or closely knit together by means of a public address system. Major units comprise the main arena seating 14,000, the Music Hall seating 2,650, the Little Theatre seating 600; and an exhibit hall containing 120,000 square feet of exhibit space. Facilities and services provided for exhibitors are sure to leave them in a happy frame of mind!

These are the convention essentials, but as no trip is complete without exploring some of the surrounding territory, what of the city itself?

Whether you appreciate fine paintings, enjoy good music, have a mechanical bent, or seek sheer recreation and entertainment, we know you will enjoy Kansas City.

In coming to the middlewest your hosts hope that you will feel you are among friends and that Kansas City will truly reflect the spirit of those who live and work here.

Under the able guidance of Health Director Dr. E. H. Schorer, plans are being made for a number of special tours and side-trips interesting from a professional standpoint. These will be described in future issues of the *Journal*.

For those who want to pursue their

individual hobbies, however, the following may constitute a sort of "vest pocket" guide. Even the briefest of exploration reveals that Kansas City is today essentially an agricultural distributing center made possible by a strategic location and ease of transportation.

Long before the days of paved roads, streamlining, or air-travel, men with high heel boots, ten-gallon hats, and clicking spurs were driving great herds of long horn cattle to Kansas City markets—markets which have now become well known for breded cattle exhibited each fall in the American Royal Livestock Show.

Vast fields of golden wheat were harvested and transported to mid-western elevators for storing and milling. These fields have earned Kansas City its reputation as the nation's "breadbasket" — and the leading market for primary winter wheat.

Long recognized as an agricultural center, the industrialist soon added his tribute. Sprawling pipelines were extended from Kansas, Oklahoma, and Texas to bring crude petroleum for refining; manufacture of corn products in Kansas City was "a natural," and soap, paint, and varnish manufacturers brought their plants here until more than 875 factories are represented in the Kansas City skyline. Today, long automobile assembly lines must be kept moving, and blast furnaces kept hot with molten steel.

To provide recreation and diversion for these people, such early builders as the late August R. Meyer, William Rockhill Nelson, and George E. Kessler planned and developed the now famous Kansas City park and boulevard system—a system which includes Cliff Drive, inviting Penn Valley Park, the 1,400 acre Swope Park, and the winding drives of the Country Club Residential district.

More recently, under a \$32,000,000

Ten Year Plan for Public Improvement, Kansas City has assumed its obligation as the artistic and cultural center of the great midwestern area it serves. Evidence might be found in the ready support given the Kansas City Philharmonic Orchestra, in the William Rockhill Nelson Gallery of Art and Mary Atkins Museum, or in any of the recently completed new municipal buildings — the Jackson County Court House, the Federal Post Office, the Municipal Auditorium, or the towering thirty story City Hall.

Within a block of the Municipal Auditorium is the Kansas City Power and Light Building which houses a small broadcasting station, television laboratories, and the Lighting Institute. Special studies have been made of color effects with reference to visibility, and a complete visual history of the lighting industry from the invention of

City Hall, Kansas City

Municipal Auditorium—Meeting Headquarters, A.P.H.A.

the first Edison bulb, is on display here. Visitors are welcome at any time and will be furnished guides between 9 A.M. and 3 P.M.

Proceeding south from downtown Kansas City, World War veterans will want to inspect the Liberty Memorial—a combined monument and building erected in honor of Kansas City's war dead. When seen after dark the 537 foot shaft constitutes a picture of great natural beauty rising on a series of terraces on which lighted fountains are directed. All Kansas City's skyline unfolds when viewed from this great height. This is in sharp contrast, however, to the wealth of factual information, maps, and war instruments contained within the memorial—a collection which merits several hours' browsing.

Directly across the street from the Memorial is the massive gray stone Union Station, popular with resident Kansas Citians and visitors alike. In addition to its extensive terminal facilities, there are always the latest books and magazines; an inviting gift shop

with the newest in gifts; a variety of toys for younger members of the family; and if one is hungry or thirsty, the Westport Room with cocktails, sizzling Kansas City steaks, and Fred Harvey's coffee.

If we continue our drive to the south we go through restful Penn Valley Park, home of Cyrus E. Dallin's Scout and A. Phimster Proctor's sculptural group, "The Pioneer Mother." Penn Valley forms a picturesque link between downtown Kansas City and its outlying shopping areas.

Largest and most outstanding of these is the Country Club Plaza, ever seasonable and festive in its decoration, and Spanish in its architecture. The Plaza, which serves Kansas City Country Club Residential District, is a complete and inviting miniature city in itself—served by its own residential parks, golf courses, bridle paths, playgrounds, and gardens.

It is said that the index to any city may be found in its homes. If this is true, a few hours spent in driving over the Country Club District justifies

William Rockhill Nelson Gallery of Art and Mary Atkins Museum, Kansas City

all Kansas City's claims to many of the nation's most beautiful homes, combining the charm of European gardens and art objects with the freshness and sense of infinite space so characteristic of the middle west.

Those with cultural interests will want to explore the building and

grounds of Kansas City's rapidly growing 6 year old University of Kansas City, the Kansas City Art Institute, or pay a leisurely visit to the William Rockhill Nelson Gallery of Art and Mary Atkins Museum.

Made possible by the bequests of Mrs. Mary Atkins and William Rock-

Overlooking the lake in Penn Valley Park, Kansas City

hill Nelson, founder of the Kansas City Star, the Gallery is erected on the grounds of Mr. Nelson's former residence, Oak Hall. More than 5,000 objects of art from the earliest civilization of Asia Minor to contemporary 20th century art are exhibited. A distinctive feature is the installation of original old panelings with complete furnishings of the period. These include an English Georgia drawing-room, a French Regina Salon, a Spanish Italian room, and an Early American wing of five interiors brought from various sections on the Atlantic coast.

The department of paintings already ranks fifth among museums of the United States and includes outstanding works by Titian, Tintoretto, Veronese, Rembrandt, Rubens, Hals, El Greco, Velásquez, Goya, Poussin, Chardin, Boucher, Greuze, Millet, Gainsborough, Reynolds, Raeburn, Copley, West, Stuart, and Inness.

Gone is the idea of a museum as a

sort of morgue filled with dim and gloomy objects out of the past. Instead, the air-conditioned scientifically lighted Kansas City Gallery achieves the effect of a series of small intimate rooms with art objects appropriately grouped as they typify life in that particular period.

Ample opportunity for outdoor sports is afforded in Kansas City's Swope Park—the third largest municipal playground in the world. Its 1,400 acres of rustic woodland, three golf courses, tennis courts, picnic grounds, shelter houses, natural footpaths, outdoor animal pits, zoo and lagoon for swimming and boating afford interest and entertainment for groups of all ages and tastes.

So for the sake of your professional interests and your own entertainment mark *October 25-28* as "red letter dates" on your calendar, and select your favorite mode of transportation. All roads lead to Kansas City!

A. Phimster Proctor's "Pioneer Mother"

HEADQUARTERS FOR THE SIXTY-SEVENTH ANNUAL MEETING KANSAS CITY, MO.—October 25-28

THE beautiful and commodious Municipal Auditorium will be used as meeting headquarters when the Association convenes for the 67th Annual Meeting in Kansas City. All scientific sessions, except breakfasts, luncheons, and dinners, will be scheduled here.

Registration and Information, commercial and scientific exhibits, Health Education and Publicity Headquarters will all be located in the Auditorium.

Residence headquarters are the Hotels Muehlebach, President, and Kansas Citian, each situated within

three blocks of the Auditorium. The members of the Vital Statistics Section and of the American Association of State Registration Executives have signified their intention of centering at the Hotel President. None of the other Sections or organizations meeting with us has named a headquarters and there will be a liberal sprinkling of all in-

terests in the three hotels. Single rooms will be difficult to obtain if reservations are long delayed. A list of Kansas City hotels with their rates is published on page 676 together with a reservation form. Fill it in now and mail it to the Chairman of the Housing Committee, Dr. Ralph Duncan, 1028 Baltimore Avenue, Kansas City, Mo.

APPLICATION FOR HOTEL ACCOMMODATIONS

In making application for hotel accommodations, it is necessary that four choices of hotels be indicated and that a reasonable range of rates desired be shown. Whenever possible, arrangements should be made for occupancy of double rooms; only a limited number of single rooms are available

HOUSING COMMITTEE
1028 Baltimore Avenue
Kansas City, Missouri

ASSOCIATION NEWS

SIXTY-SEVENTH ANNUAL MEETING

Kansas City, Missouri

October 25-28, 1938

HEADQUARTERS: HOTELS MUEHLEBACH, PRESIDENT, AND KANSAS CITIAN

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Wofford E. Baldwin, M.D., St. George, S. C.,
Acting Director, Dorchester County Health
Dept.

O. H. Cheek, M.D., Dublin, Ga., County
Commissioner of Health

H. Burton Doust, M.D., 302 City Hall, Syra-
cuse, N. Y., Commissioner of Health

Harold M. Erickson, M.D., The Dalles, Ore.,
Medical Director, Wasco County Health
Unit

Alfred E. Eyres, M.D., Court House, Walla
Walla, Wash., City and County Health
Officer

William Fraden, M.D., 1634 Popham Ave.,
New York, N. Y., District Medical Super-
visor, Dept. of Health

Ben Freedman, M.D., Franklinton, La., Direc-
tor, Washington Parish Health Unit

Ralph T. Frisbee, Whitehall Rd., Amesbury,
Mass., Agent and Secretary, Board of
Health

Eugene A. Gillis, M.D., Dyersburg, Tenn.,
Director, Dyer County Health Dept.

Frank M. Hall, M.D., Athens, Ala., Lime-
stone County Health Officer

Robert H. Haralson, M.D., Box 456, Tifton,
Ga., Tift County Commissioner of Health

Eugene F. McGillian, M.D., 317 City Hall,
Yonkers, N. Y., Commissioner of Health

Chris L. Mengis, M.D., P. O. Box 547, Winns-
boro, La., Director, Franklin Parish Health
Unit

Rufus F. Payne, M.D., State Health Dept.,
Atlanta, Ga., Assistant Director, County
Health Work

Gordon E. Savage, M.D., N. West St., Xenia,
O., Greene County Health Commissioner

Herbert C. Schenck, M.D., 11 Hunter St.,
S.W., Atlanta, Ga., Director, Division of

Tuberculosis Control, State Dept. of Health

Samuel Steinholtz, M.D., 239 Snediker Ave.,
Brooklyn, N. Y., Deputy Medical Super-
intendent, Harlem Hospital

John P. Walsh, M.D., Drawer C. Greenview,
Ill., District Health Supt., State Dept. of
Public Health

Roy H. Wilson, M.D., 207 Rencher St.,
Clovis, N. Mex., Deputy District Health
Officer

Laboratory Section

Fred J. Baker, P. O. Box 899, Douglas, Ariz.,
Sanitarian, Cochise County Health Dept.

Gail W. Dalrymple, 1806 Maple Ave.,
Evanston, Ill., Director, Division of Labs.,
Dept. of Health

Carl F. Dunker, 15 W. Glen St., Holyoke,
Mass., Junior Chemist, State Dept. of Public
Health

Arthur P. Dunnigan, Ph.D., Minn. Dept. of
Health, University Campus, Minneapolis,
Minn., Bacteriologist, Division of Prevent-
able Diseases

Harry L. Edwards, 608 S. Dearborn St.,
Chicago, Ill., Pure Milk Assoc.

Margaret L. Flanagan, 420 Sixth Ave. N.,
Nashville, Tenn., Technician, State Dept.
of Public Health

Frances I. Friewer, Diagnostic Lab., Division
Health, Springfield, Ill., Junior Bact'

Harriet M. Goodman, 16 Seaman Drive, Los

Brunswick, N. J., Bacteriologist, E. R. Squibb & Sons
 Glen H. McLaughlin, 303 E. 9th, Austin, Tex., Water Analyst, State Dept. of Health
 Juan A. Montoya O., M.D., 615 N. Wolfe St., Baltimore, Md., Student
 Carolyn Oldenbusch, 72 Marlborough Rd., Brooklyn, N. Y., Bacteriologist, Dept. of Health
 Andrew J. Pensa, 15 Gelston Ave., Brooklyn, N. Y., Chemist, Dept. of Health
 Ralph H. Tanimoto, 2110-A Date St., Honolulu, T. H., Laboratory Technician, Board of Health
 Joseph C. Wenger, 1801 S. LaCienega, Los Angeles, Calif., Laboratory Technician, Adohr Milk Farms

Vital Statistics Section

Jean C. Bowman, International House, Berkeley, Calif., Student
 Louis Feldman, Opelika, Ala., Statistical Clerk, State Dept. of Health
 Clifford L. Harlan, Rm. 203, City Hall, Peoria, Ill., Statistician, Health Dept.
 Frank S. Morrison, 1665 S. Lincoln St., Denver, Colo., Director, Division of Vital Statistics, State Dept. of Health

Public Health Engineering Section

Inga M. K. Allison, 120 Garfield St., Fort Collins, Colo., Dean, Division of Home Economics, Colorado State College
 Wade H. Bolton, Silver City, N. Mex., District Sanitarian
 John M. David, Statesboro, Ga., Sanitary Engineer, Bulloch County Health Dept.
 Robert A. Dean, Box 354, McRae, Ga., District Sanitarian, Telfair-Wheeler Health Dept.
 Lewis W. de Jarnette, 120 Clairmont Ave., Decatur, Ga., Sanitarian, DeKalb County Board of Health
 Wendell J. Erickson, Loudon Lane, Loudonville, N. Y., Assistant Sanitary Engineer, State Dept. of Health
 Arthur W. Ferguson, 483 Orange St., Macon, Ga., Sanitarian, Bibb and Jones County Health Depts.
 Adolph G. Franksen, 1806 Maple Ave., Evanston, Ill., City Food and Dairy Inspector
 Gilbert R. Frith, 1425 McPherson Ave., S.E., Atlanta, Ga., Assistant Engineer, State Board of Health
 Lawrence B. Hall, C.P.H., P. O. Box 103, Swainsboro, Ga., Assistant Engineer, State Board of Health
 Eugene C. Harrison, 416 W. Poplar St., Griffin, Ga., County Sanitarian, Spalding County Health Dept.

Carl E. Henderson, 110 W. Shaw, Carlsbad, N. Mex., District Sanitarian
 Patrick L. Hughes, 423 Williams, Waycross, Ga., Assistant Division Engineer, State Health Dept.
 Erich W. Kearney, P. O. Box 34, Morganton, N. C., Assistant Engineer, State Board of Health
 Breadon W. Kellogg, 1578 Florence Ave., Evanston, Ill., City Sealer
 William A. Legwen, 501 Greene, Augusta, Ga., Sanitary Engineer, Richmond County Health Dept.
 Richard E. Lindsay, 1024 Noyes St., Evanston, Ill., Housing and Sanitation Inspector, Board of Health
 Charles W. Matheny, Jr., Laurens County Health Dept., Dublin, Ga., County Sanitarian
 James H. Menefee, 814 Monroe St., Jefferson City, Mo., Sanitary Engineer, State Board of Health
 James N. Newman, 65 E. Spring St., Gainesville, Ga., Sanitarian, Hall County Health Dept.
 Walter P. Rial, Shanghai Waterworks Co., Ltd., Shanghai, China, Engineer-in-chief
 L. Glen Shields, 555 Clinton, Detroit, Mich., Associate Sanitary Engineer, City Dept. of Building
 Elmer C. Slagle, Rm. 115, Court House, Duluth, Minn., Public Health Engineer, District #4, Minnesota Dept. of Health
 Henry B. Starr, Jr., 6 Hardeman Bldg., Macon, Ga., Assistant Engineer, State Dept. of Health
 Clarence J. Velz, 327 North Ave., Fanwood, N. J., Senior Engineer, Region #1, FPWA
 John E. Waaser, 488 Fairbanks Ave., Oakland, Calif., Student—Sanitarian
 C. H. Watson, 1228 E. Center, Pocatello, Idaho, Sanitarian, State Dept. of Public Welfare
 Dudley M. Williams, Box 1482, Santa Fe, N. Mex., Student at present at Univ. of Calif.
 Myron J. Woodman, 1123 Noyes St., Evanston, Ill., City Food and Dairy Inspector
 Hallock W. Woodworth, D.D.S., 816 Oregon Bldg., Portland, Ore., Assistant State Director, Community Sanitation, U. S. Public Health Service

Industrial Hygiene Section

William R. Bradley, 1151 Taylor Ave., Detroit, Mich., Junior Sanitary Engineering Aid, Dept. of Health
 Frank N. Chirico, 210 Commonwealth Bldg., Harrisburg, Pa., Chemical Engineer, Division of Industrial Hygiene, State Dept. of Health

Allan E. Dooley, 210 Commonwealth Bldg., Harrisburg, Pa., Senior Chemist, Division of Industrial Hygiene, State Dept. of Health
 Nathan Gales, 2492 DeVoe Terrace, New York, N. Y., Chemist, Dept. of Health
 Walter D. Higgins, M.D., 6 Park St., Peabody, Mass., Industrial Surgeon
 Julia L. Matthews, Ph.D., 210 Commonwealth Bldg., Harrisburg, Pa., Senior Chemist, Division of Industrial Hygiene, State Dept. of Health

Food and Nutrition Section

Frances B. Bowen, St. Luke's and Children's Hospital, Philadelphia, Pa., Dietitian
 Willard H. Boynton, 310 Cedar, New Haven, Conn., Student
 Elmer E. Harter, Jr., Dept. of Agriculture, Harrisburg, Pa., Director, Bureau of Foods and Chemistry
 Morris B. Jacobs, Ph.D., 355 Bradford St., Brooklyn, N. Y., Chemist, Dept. of Health
 Cecilia Schuck, Ph.D., Purdue University, W. Lafayette, Ind., Instructor in Nutrition

Child Hygiene Section

Hugh J. Bickerstaff, M.D., State Dept. of Health, Atlanta, Ga., Assistant Director, Child Hygiene
 Lela Ewert, 510 W. Palm Lane, Phoenix, Ariz., Physical Therapy Technician, Crippled Children's Division, State Board of Social Security and Welfare

Public Health Education Section

Delmar I. Allman, Dr.P.H., 136 N. 9th St., Corvallis, Ore., Associate Professor of Hygiene and Physical Education, Oregon State College
 Doris G. Chandler, C.P.H., 171 Haili St., Hilo, T. H., Executive Secretary, Tuberculosis Society of Hawaii
 Charles M. Cree, State Dept. of Public Health, Santa Fe, N. Mex., Director, Health Education

SKIN IRRITANTS REPORT AVAILABLE

HENRY Field Smyth, M.D., Dr.P.H., of the University of Pennsylvania, Philadelphia, Pa., has prepared a report representing a combination of the last three Skin Irritants reports presented to the Industrial Hygiene Section, A.P.H.A., and covering a 9 year period from 1926 to 1934, completely indexed by author and subject.

The U. S. Public Health Service has had these reports mimeographed, comprising 211 pages, and a limited number of copies are available.

Those interested may obtain copies by writing to J. J. Bloomfield, P. A. Sanitary Engineer, National Institute

of Health, U. S. Public Health Service, Washington, D. C.

PUBLICATIONS NEEDED

THE Association stock of these issues of the *Journal* is almost depleted:

January,	1937
February,	1937
July,	1937
January,	1938

If any members can spare copies of these numbers, the Executive Office will much appreciate it if they will kindly send them to headquarters, at 50 West 50th Street, New York, N. Y.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Joint Vocational Service, 122 E. 22 Street, New York, N. Y., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS WANTED

HEALTH OFFICERS

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; now employed. is available for venereal disease control officer. A363

Physician, M.D., Johns Hopkins; public health course at Michigan; experienced in school and city health work, will consider an administrative post in eastern United States. A354

Physician, M.D., Northwestern University; Dr.P.H., Yale; will consider appointment in general administration, infant welfare or epidemiology. A300

Physician, M.D., Tufts; C.P.H., Johns Hopkins; administrative experience large city health department, will consider position as health officer or epidemiologist. A362

Physician, M.D., C.P.H.; 2 years' experience as district health officer, anxious to do venereal disease control work or epidemiology. A345

CHILD HYGIENE

Experienced physician, M.D. and Ph.D., University of Minnesota, specially qualified in maternal and child hygiene, directing state and local programs; will consider position of better sort. A238

HEALTH EDUCATION

Young woman, Ph.D., Yale University, experienced in the field of bacteriology and immunology, will consider position in health organization or education. M324

Young man, at present college teacher of hygiene and physical education and experienced in university medical services, desires position as executive in public or private health organization. M357

LABORATORY

Young man, A.B. in Chemistry, Phillips University; M.S. in Public Health Laboratory Work, University of Michigan; desires position in state or city health department laboratory. L304

Young woman, M.S., University of Michigan, experienced in biochemistry, bacteriology, water analysis and blood work, will consider research position. L322

Man, with Bachelor of Bacteriology degree, medical courses at University of Maryland for 4 years, seeks position as bacteriologist with investigation work, as laboratory director or as instructor in public health. L281

MISCELLANEOUS

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

Young man, Sc.D., Johns Hopkins; experience in public health and research bacteriology; will consider position in public health or university teaching. L312

Graduate Sanitary Engineer with service under U.S.P.H.S. and State Departments of Health, specially interested in filtration plant design and operation and shellfish sanitation, seeks employment. E356

Young man, M.S.P.H., Michigan; B.S., Muskingum College; desires position in county unit or as sanitarian for city. Seven years' teaching experience. Interested in case work. M364

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

While the following list does not show all universities and technical schools offering summer courses in public health, it represents those who have replied to a questionnaire sent out by the American Public Health Association.

American National Red Cross

Courses in Teacher Training for Home Hygiene Instruction:

- University of California, Los Angeles, Calif.—June 25–August 5
- Colorado State College, Fort Collins, Colo.—July 9–August 19
- Peabody College, Nashville, Tenn.—June 6–July 13
- University of Pennsylvania, Philadelphia, Pa.—June 27–August 9

The National Society for the Prevention of Blindness, Inc., New York, N. Y.

Sight-saving classes:

- State Teachers College, Buffalo, N. Y.—July 5–August 12
- Teachers' College, Columbia University, New York, N. Y.—July 6–August 13
- Tulane University, New Orleans, La.—June 13–July 23
- University of Cincinnati, Cincinnati, Ohio—June 20–July 26
- University of Hawaii, Honolulu, T. H.—June 27–August 5
- University of Washington, Seattle, Wash.—June 20–July 20
- Wayne University, Detroit, Mich.—June 27–August 5

University of California, Berkeley, Calif.

June 27–August 5

- General Bacteriology
- Child Development
- Physiology of the Growth and Development of Children
- Administration of the School Health Program

- Principles of Health Teaching for Nurses
- Administration and Organization of Public Health Nursing
- Principles and Practice in Public Health Nursing
- Introduction to Educational Psychology
- General Psychology
- Elementary Epidemiology *
- Elementary Public Health *
- Public Health Administration *
- Communicable Diseases *

* These four courses are offered in the Inter-session, May 16–June 24

University of California at Los Angeles, Los Angeles, Calif.

June 27–August 5

- Elementary Bacteriology
- Growth and Development of the Child
- Adolescence
- Mental Hygiene
- Administration of the School Health Program
- Principles of Teaching as Applied to Home Hygiene Courses
- Methods in Teaching Home Hygiene Courses with Practice Teaching
- Essentials of Nutrition
- General Psychology
- Educational Psychology
- Public Health and Preventive Medicine
- Principles and Practice of Public Health Nursing
- Social Case Work as Related to Public Health Nursing
- General Zoölogy
- Social Pathology

The Catholic University of America, Washington, D. C.

SYPHILIS COURSES

ONE DAY institutes on syphilis for practising physicians will be held by the Medical Society of the State of New York in coöperation with the State Department of Health.

The courses will include instruction in the pathology, etiology, diagnosis, and treatment of syphilis, and the organization and administration of syphilis control programs will be outlined. These institutes will be conducted in the following cities:

Albany—May 26–27

Binghamton—May 24–25

Jamestown—May 23

New York—May 23–24

Syracuse—May 18–19

Watertown—May 20

Physicians wishing to attend any of these institutes should file applications with the District State Health Officer, or: Thomas P. Farmer, M.D., New York State Medical Society, 608 East Genesee Street, Syracuse, N. Y.

BIRTH REGISTRATION CIRCULAR

A CIRCULAR entitled "What Happens When Birth Registration Goes Amiss" has been issued by the Maryland State Department of Health, Baltimore. It is being sent to all physicians, midwives, and public health nurses in Maryland.

NATIONAL HEALTH CONFERENCE

MISS Josephine Roche, Chairman of the President's Interdepartmental Committee to Coördinate Health and Welfare Activities, recently announced that development of a national health program will be studied at a forthcoming public conference to be held in Washington.

She said the conference had been arranged at the suggestion of President Roosevelt. In a letter to her, he suggested:

"... that your committee give consideration to the desirability of inviting at some appropriate time representatives of the interested public and of the medical and other professions to examine the health problems in all their major aspects, and to discuss ways and means for dealing with these problems."

Invitations, it was said, would be sent to representatives of the medical and other professions and many other groups.

DEATH CERTIFICATES FOR NEW YORK

NEW death certificate forms are being prepared, Health Commissioner John L. Rice, of New York, N. Y., has announced.

These forms have a separate section devoted entirely to causes of death, which information is to be kept strictly confidential and may not be used in court cases.

The Queens County Medical Society and other county medical groups aided in drawing up these forms, which are expected to lead to more honest reporting on deaths.

CHICAGO TUMOR INSTITUTE

THE Chicago Tumor Institute was opened March 21.

It offers consultation service to physicians in the diagnosis and treatment of cancer and radiation facilities for cancer patients.

The Institute also proposes to conduct research and to offer training to physicians who may wish to qualify as

specialists in the study and treatment of this disease.

WESTERN BRANCH A.P.H.A.

THE Ninth Annual Meeting of the Western Branch American Public Health Association will be held in Portland, Ore., June 6-8, with headquarters in the Hotel Multnomah.

There will be papers on public health administration, a symposium on syphilis, a panel discussion on public health nursing functions, papers on high school and college hygiene, a discussion on plague, and papers on public health laboratory procedures. Concurrently with the Western Branch meeting will be the Annual Conference of State Supervisory Nurses, the Annual Conference of the City and County Health Officers of Oregon, the Annual Meeting of the Washington State Public Health Association, the Annual Meeting of the Oregon Nutrition Council, and the Conference of the Pacific Coast Branch of State Registration Executives.

There will be visits to various points of interest within the city and an excursion to Multnomah Falls and Bonneville Dam. The program committee expects the meeting to be the most successful yet held in the history of the Western Branch, both from the standpoint of scientific material to be presented and the entertainment to be given the delegates and guests.

CONFERENCE OF STATE AND PROVINCIAL
HEALTH AUTHORITIES ELECTS
NEW OFFICERS

AT the annual session of the Conference of State and Provincial Health Authorities of North America, held in Washington in April, the following officers were elected:

President—Felix J. Underwood, M.D., Executive Officer, State Board of Health, Jackson, Miss.

Vice-President—John T. Phair, M.B.,

C.P.H., Chief Medical Officer of Health, Provincial Department of Health, Toronto, Ont.

Secretary-Treasurer—A. J. Chesley, M.D., State Health Officer, St. Paul, Minn.

HEALTH OFFICERS HONORED

THE State and Provincial Health Authorities of North America, on April 10, honored Health Officers from the United States and Canada who had served for 25 years or longer. Among present and former members of the conference honored were the following:

Cornelius A. Harper, M.D.
Thomas R. Crowder, M.D.
Henry E. Young, M.D.
James A. Hayne, M.D.
Frederick E. Trotter, M.D.
Theodore B. Beatty, M.D.
Arthur T. McCormack, M.D.
Charles F. Dalton, M.D.
William F. Cogswell, M.D.
John A. Ferrell, M.D., Dr.P.H.

KANSAS COUNTY HEALTH OFFICERS

ANNOUNCEMENT has been made of recently appointed county health officers in the State of Kansas. They are:

Edwin R. Hill, Jr., M.D.—Lyons, Rice County
August A. Meyer, M.D.—Alma, Wabaunsee County
Orlin P. Wood, M.D.—Marysville, Marshall County
Alfred J. Horejsi, M.D.—Ellsworth, Ellsworth County
Benjamin Brunner, M.D.—Wamego, Pottawatomie County
Raymond W. Moore, M.D.—Eureka, Greenwood County
Frank A. Trump, M.D.—Ottawa, Franklin County
Franklin R. Croson, M.D.—Clay Center, Clay County
Benjamin L. Phillips, M.D.—Paola, Miami County
Leon W. Zimmerman, M.D.—Liberal, Seward County
Ivan B. Parker, M.D.—Hill City, Graham County

Reappointment has also been announced of the following county health officers:

Spencer B. Dykes, M.D.—Esbon, Jewell County

Robert J. Lanning, M.D.—Junction City, Geary County

Donald A. Bitzer, M.D.—Washington, Washington County

WISCONSIN APPOINTMENTS

THREE new officers were recently elected to the Wisconsin State Board of Health. They are:

President—Dr. John J. Seelman, of Milwaukee

President-elect—Dr. William W. Kelly, of Green Bay

Vice-President—Dr. Joseph Dean, of Madison

FRENCH INSTITUTE FOR THE PREVENTION OF OCCUPATIONAL DISEASES

IN December, 1937, the Minister of Labour established the Institute for the Study and Prevention of Occupational Diseases, in Paris.

This Institute, the first of its kind in France, includes not only a modern, well equipped examination room, but also a laboratory permitting extensive chemical and toxicological research and a special photographic laboratory.

A library offers to its readers literature, bibliographies, and all specialized publications in French, English, Dutch, German, and Russian, as well as the publications of the International Labour Bureau. A complete catalogue classifies, under the various headings, all the published articles dealing with the subject of occupational pathology and hygiene.

The Institute, directed by Dr. G. Hausser, includes on its scientific board such well known French scientists as Professors Balthazard, Tiffeneau, Duvoir, Etienne-Martin, Fabre, Kohn-abrest, Laugier, Godard, and Mazel.

A publication appearing every two months, *Archives des Maladies Professionnelles D'Hygiene et de Toxicologie Industrielles*, will include extensive

scientific tracts and a complete bibliographical section.

MICHIGAN BLOOD TESTS

PREMARITAL blood tests in the State of Michigan disclose an average of 45 cases of syphilis a month among applicants for license to wed, according to a report by State Health Commissioner Don W. Gudakunst.

CHANGES IN CALIFORNIA

THE City of India, Calif., has transferred its public health administration to the Riverside County Health Department. The Santa Cruz County Health Department is now administering the public health affairs of the City of Santa Cruz.

ILLINOIS TO STANDARDIZE LABORATORY PROCEDURES

THE Illinois State Department of Health has appointed a special committee to standardize diagnostic laboratory procedures. The list of committee members includes the following names:

Dr. Lewis R. Hill, Assistant Professor of Bacteriology and Preventive Medicine, Loyola University College of Medicine, Chicago

Dr. John L. White, Chief, Bureau of Laboratories, Board of Health, Chicago

Dr. Lloyd Arnold, Professor of Public Health, University of Illinois College of Medicine, Chicago

Dr. Reuben Kahn, Director of Laboratory, University Hospital, University of Michigan, Ann Arbor

LOUISIANA OYSTER RULING

THE Louisiana State Board of Health has ordered that all shipments of shell oysters without identification tags be discontinued. This is in accordance with a recently revised federal law. Dealers will supply these tags to the oyster fishermen and thus facilitate the tracing of oysters to the bedding grounds should any illness result from their use.

NORTH CAROLINA PNEUMONIA COMMISSION

APNEUMONIA commission has been established by the North Carolina State Board of Health in coöperation with the Medical Society of North Carolina and Duke University School of Medicine. This commission is under the chairmanship of Dr. Hubert B. Haywood, of Raleigh.

VETERINARIANS TOUR

THE official European tour of the American Veterinary Medical Association, to attend the Thirteenth International Veterinary Congress, to be held in Zurich and Interlaken, Switzerland, August 20-27, 1938, has been announced. The sailing date is July 13, return September 15.

A comprehensive itinerary, of general and professional interest, has been planned. Preparations have been made to receive the delegation at various institutions of importance. Dr. Adolph Eichhorn, of Pearl River, N. Y., will be in charge of the professional program, as previously.

Rates and other information will be furnished by Treasure Tours, Inc., 70 West 40th Street, New York.

DEATH

DR. BERTHA KAPLAN SPECTOR,† research associate in medicine at the University of Chicago, Chicago, Ill., died March 26. She was known for her work in amebic dysentery.

PERSONALS

Central States

ROBERT H. BELL, M.D.† Health Officer of Carlinville, Ill., has been appointed full-time Superintendent of the District Health Unit composed of the Counties of Scott, Morgan, Greene, Calhoun, Jersey, and Macoupin.

JOSEPH BLICKENSERFER, M.D.,*

* Fellow A.P.H.A.

† Member A.P.H.A.

Health Officer of New Philadelphia, Ohio, was honored with a testimonial dinner by the Tuscarawas County Medical Society, January 14, celebrating his completion of 50 years of practice.

DR. REUBEN J. HARRINGTON, of Muskegon, Mich., has been appointed Health Officer of Muskegon County.

THURMAN B. RICE, M.D.,† Professor of Bacteriology and Public Health at Indiana University School of Medicine, has been made Chairman of the University's newly formed Department of Bacteriology and Public Health; and DR. FRANK FORRY, Professor of Pathology, has been appointed Chairman of the new Department of Pathology.

Eastern States

EARLE G. BROWN, M.D.,* former State Health Officer of Kansas and recently Director of Health and Welfare in Arlington County, Va., has been appointed Commissioner of a newly established health unit in Nassau County, New York, N. Y.

DR. JOHN L. LAIRD has been appointed Chief of the Division of Laboratories in the Philadelphia (Pa.) City Department of Health.

FREDERICK W. NORDSIEK, S.B.,† has become associated with the Department of Nutrition of the American Institute of Baking, New York, N. Y. For the present, he is continuing as Secretary of the New York Diabetes Association.

BOSSE B. RANDLE,† of New York, has been appointed Director of Public Health Nursing in the new Nassau County Department of Health, Mineola, L. I. Miss Randle has recently been on the staff of the New York State Department of Health and Teachers College, Columbia University.

* Fellow A.P.H.A.

† Member A.P.H.A.

DR. EVELYN F. H. ROGERS, of Bedford Hills, N. Y., has been appointed Epidemiologist-in-training in the New York State Department of Health, and after a year's study will be assigned to the Division of Maternity, Infancy and Child Hygiene.

DR. ABEL WOLMAN, Chief Engineer, Maryland State Department of Health, Baltimore, Md., and President-elect of the American Public Health Association, will speak on the subject "Benjamin Franklin, Printer and Businessman," at the Dedication Program of the Franklin Institute, Philadelphia, Pa., on May 21.

Southern States

WOFFORD E. BALDWIN, M.D.,† formerly of Due West, S. C., has been appointed Health Officer of Dorchester County.

DR. FRANK M. ROGERS, formerly of Coleman, Ga., has been appointed Health Officer of Crittenden County, Ky., with headquarters at Marion, Ky.

DR. ELMER K. UMBERGER, formerly of Trinity, Tex., has been appointed Health Officer of McCreary County, Ky.

Western States

DR. JAMES EDDY ARNOLD, of Miles City, Mont., has been appointed Village Health Officer, and School Physician for Mountain Iron, Minn.

DR. MARGARET E. HATFIELD, of Janesville, Wis., has been appointed Health Director of Rock County, as part of an enlarged health program made possible by a federal grant. Dr. Hatfield has been serving part time in this position.

EDYTHER HERSHEY, M.D.,† has become Director of the Division of Child Welfare of the Montana State Board of Health, Helena. Dr. Hershey has for some months been associated with

the Children's Bureau, Department of Labor, Washington.

DR. LYNN J. LULL, formerly in private practice in Olathe, has been appointed Health Officer of the first full-time county health unit in Colorado recently opened in Otero County, with headquarters in La Junta. The unit is maintained jointly by the county and the state in coöperation with the Otero County Medical Society.

DR. MARCUS W. PASCOE has been appointed Health Officer of the city of Shafter, Calif., in Kern County, recently incorporated.

DR. FELIX R. ROSSI, JR., has been appointed Health Officer of Fairfield, Calif., to succeed DR. CARLTON C. PURVIANCE.

Canada

A. GRANT FLEMING, M.D., D.P.H.,* of McGill University, Montreal, Que., has been appointed a member of the Medical Research Committee formed by the National Research Council of Canada, to study the organization of medical research in Canada.

Philippine Islands

DR. EUSEBIO D. AGUILAR, of Manila, P. I., has been appointed Director of the Bureau of Public Welfare for the Islands.

DR. GREGORIO LANTIN, of Manila, has been made head of the medicolegal section of the Department of Justice.

* Fellow A.P.H.A.

† Member A.P.H.A.

Problems of a Housing Enforcement Program

L. M. GRAVES, M.D., AND ALFRED H. FLETCHER, F.A.P.H.A.

*Superintendent; and Sanitary Engineer, Department
of Health, Memphis, Tenn.*

THE diagnosis of the problem of providing decent and sanitary homes for the lowest income group seems to be definite and clear-cut, and yet its solution is many sided. The diagnosis is poverty—poverty of the tenants and poor income to the owners of the slum dwellings. The solution, however, is not simply that of publicly subsidized housing, enforcing sanitary and housing ordinances, slum clearance, great private housing developments—nor all these together.

The solution in its entirety must include provisions for people who are poor; those who have no steady jobs; those on relief; those who are old or blind; those whose husbands may be habitual drunkards or known by social agencies as "good for nothings"; those whose income will permit the payment of only \$1 a week rent for the entire living unit whether they need 1 room or 5 rooms; those who can pay only \$2 a week rent; and those who can pay only \$3 a week rent for the entire living unit. In Memphis this group includes approximately 50 per cent of the population, 80 per cent of this 50 per cent

being negroes. These are facts and not estimates.

It is the problem of housing poor people, then, which to public health departments and possibly to other interests is the most important of all. Without an attack on this lowest income group, there will be no permanent, substantial, public health improvement. Sanitary facilities in the home cannot be rented or maintained under present conditions by poor people. There is no agency or program now aimed, at least not so as to hit the bull's-eye, at this lowest income group. Some, in fact most, of the above listed groups in which the greatest housing needs exist, are not eligible for housing in federal housing projects.

There is some truth in the oft repeated statement that

... new large scale good housing built for the large middle class income groups will release moderately good housing for occupancy by the next lower income groups, bringing about a general upward movement that will empty slum properties for the wreckers.

However, studies of the slums in

Dilapidated Houses in the \$1 to \$1.50 a Week Rental Class

Memphis indicate that this oft repeated quotation is not complete and should be amended to read:

... new large scale good housing for the large middle class income groups will release moderately good housing for occupancy by the next lower income group, bringing about a general upward movement of people that will empty many slum properties for the wreckers and will thus take the cause of slums into slightly better housing to turn it into a slum for future emptying.

A slum is a slum because there is no income, or insufficient income to build or maintain the housing in a decent or sanitary condition. An upward movement of poor people into a better housing area can bring blight and disaster to any district with distressing rapidity. In the long run, \$1 a week will rent a \$1 a week house and \$2 a week will rent a \$2 a week house.

In trying to arrive at the solution, it should be recognized that an average figure or picture of housing or slums for the United States may be misleading for any individual section, or city of the United States. An average picture of conditions for the country as a whole, based on actual facts and not estimates and guesses, may indicate that 9.6 per cent of the shortage in non-farm family dwelling units exists in the rental group paying less than \$10 a month rent, while a picture of conditions in Memphis indicates that this figure if used to show needs for housing is grossly misleading. Eight and six-tenths per cent of all dwellings in the city are dilapidated to the point that it would not be practical to attempt patching or remodeling to meet a minimum standard. These dilapidated dwellings are occupied by the people in

† "The housing index is a numerical value computed for each dwelling and for each block of dwellings, and indicates that the block averages a certain per cent of a minimum standard. The 0 to 29 per cent group, for example, includes all blocks whose average housing index for all dwellings in the blocks is less than 30 per cent of a minimum standard. The minimum standard arbitrarily adopted for Memphis is a dwelling that is constructed reasonably tight to protect the occupants from the weather; screened for protection against flies and mosquitoes; provided with inside private wash-down toilets; a water faucet and sink connected to the sanitary sewer; served by the municipal water supply; provided with adequate natural light and ventilation; having adequate provisions made for the use of heating facilities; facing a street and in a reasonable state of repair."

"The key facts for judging the dwellings surveyed are: (1) Location, condition, and use of toilet; (2) location, condition and use of water and sink; (3) condition of screens, roofs, floors, walls, ceilings, and chimneys; (4) the number of families provided for by the dwelling; (5) the number of persons housed per room; (6) the position of the dwelling on the lot (front or rear).

These factors when assigned more or less arbitrary numerical values, with deductions for unsatisfactory condition of the various items, give a picture of the degree of bad housing in comparison with the accepted minimum. The resulting figure for a dwelling is called the sanitary rating or factor. By grouping dwellings into blocks of dwellings, and combining with this figure the value referred to as a rear dwelling factor, a picture is obtained of conditions as they vary from block to block and area to area.

The scoring system is based on the allowance of such credit for the number (and in some cases the convenience) of water supply facilities and toilets, as well as for the general structural condition of the dwelling and for the number of persons housed per room. Deductions are made, depending on the degree of unsatisfactoriness of these items." The system of grading is described in detail in "A Yardstick for Slums," by Alfred H. Fletcher, *Engineering News Record*, August 26, 1937.

the \$10 and under rent group. Seventy-three per cent of the colored and 6 per cent of the white population, or 34.5 per cent of the total population, live in the poorest of substandard housing and pay less than \$9 a month rent. Other figures prove beyond a doubt, if need is the criterion used, that the greatest need for housing in Memphis is in the \$10 a month or less rent group. This group is not, of

course, of interest to private capital since the returns are not sufficient for the most part to meet expenses.

MEMPHIS PROGRAM

In an attempt to develop a fundamentally sound housing enforcement program, the Department of Health has made a series of studies as to the make-up of the Memphis slums. The first survey in 1933 and 1934 which

covered the entire city, seemed to show a definite relationship between outdoor communal toilets and typhoid fever, and between housing when grouped according to a housing index and infant mortality. The second study in 1936 and 1937 indicated that a slum is not uniform and may be classified into varying degrees of "slumness," with cores of the very worst type of slum in the center or centers, and varying degrees of progressively better slum housing radiating out from the centers or cores to the rim or blighted area. This blighted rim serves as a barrier between the slums and standard housing areas.

Table I summarizes the results of the 1936 and 1937 study, which was previously discussed in an article by the authors,¹ when the study was about 40 per cent completed. This table presents data from approximately 80 per cent of the total substandard housing areas of Memphis.

This two year summary verifies the conclusions of the 1936 report that,

The law of supply and demand is plainly indicated. As the rents decrease the housing gets worse, the vacancies increase, crowding increases, and rooms per unit decrease. It would seem to point the way to where to apply enforcement proceedings in order to get the greatest returns for effort expended. Private capital getting reasonable rents and not furnishing a minimum standard house should be forced, and should welcome this enforcement on all owners without exception, to meet the standard in order to bring all houses in the blighted areas up to a decent standard. However, any effort to enforce minimum standards in the very low rental slum areas where the existing conditions are very bad can result only in slum clearance. This effort is worth while only where there is a sufficient per cent of vacancies, and should be directed toward the elimination of the worst dwellings.

FUTURE PLANS

The question may well be asked, as a result of these studies, what are the plans for the future housing enforcement program of the Department of

Health and what will this program accomplish in the way of improving existing conditions? As a result of these studies up to the present time, when viewed from a public health standpoint, several fundamental facts stand out:

1. The poorest people live in the poorest houses for which the lowest, if any, rents are collected.

2. There is a definite correlation between rents paid and the score made by the dwellings as judged from the standpoint of housing conditions by the Department of Health.

3. In view of the facts upon which the second fundamental statement made above is based, there seems to be some basis for the assumption that much of the public resentment, as well as the resentment of students of housing, against the greed and selfishness of owners of slum housing is unwarranted. The number of conveniences and sanitary facilities and their maintenance improve where economic rents are paid and decrease directly as rents decrease.

4. It is felt that if a planned concerted drive is made for the strict enforcement of a housing ordinance on the section of the slum paying the best rents, much permanent good can be accomplished in securing minimum standard housing and minimum standard housing areas or neighborhoods. Such a program should and will enlist the hearty cooperation of property owners who will benefit by this uniform enforcement for a neighborhood.

The blighted area or outer rim of the slum characterized by higher rents and better sanitation is undoubtedly the most promising field for securing improvements by an energetic enforcement program. Owners are better able to meet these demands because of better returns, and the general improvement of the area as a unit will be helpful in attracting paying tenants as the dilapidated, insanitary houses in this area are brought up to the minimum standard or are vacated and torn down. Of course, the tenant paying less than an economic rent will be forced to pay more or move. A gradual screening or squeezing program of this sort will

Memphis Houses with Outdoor Communal Toilets and Water

Houses on the South Side of West Memphis

eventually progress to the point where the owners will find it uneconomical to meet the demands of the Department of Health and houses will be vacated and in many cases torn down as the demands are enforced. This point will be reached when the "illusive sharp dividing line which is obviously impossible to determine" is reached. It seems that few cities have used the enforcement weapon in the most strategic manner in improving and decreasing the size of their slums. It is planned to continue the enforcement program in Memphis as initiated early in 1936 along the lines suggested above.

ENFORCEMENT AGENCIES AND PUBLICLY SUBSIDIZED HOUSING AGENCIES BOTH WORKING ON TOP SECTION OF SLUMS

It may be noted here that the enforcement agencies and the publicly subsidized housing programs are both working on this top section of the slums. The term "subsidized housing agency" as

used in this paper refers to any agency that does now, or might be set up in the future to assist tenants individually, or as a group, in obtaining a minimum standard house by subsidizing their rent, either indirectly through capital grant subsidy or annual rent subsidy to the tenant, or indirectly through individual rent subsidy to the individual owner of houses rented to eligible tenants, or in any other similar manner.

In an attempt to visualize the housing problem in Memphis and to illustrate the present weakness in the method of attack, two charts have been prepared showing the population of Memphis as a bar or a column and showing the per cent of people in Memphis in certain classes or groups as per cents of the length of the bar. One of these charts is based on figures from the 1933-1934 housing survey of the entire city and the other is based on figures from the 1936-1937 studies of the slums and blighted areas of Memphis.

Chart I representing the 1933-1934 figures, indicates that over one-half of the population of Memphis pay less than \$3 per week, or \$13 per month rent for the entire living unit. It can also be noted that a very large part of this group paying such a low rent are negroes and that almost the entire negro population fall within this very low rental classification. Our housing problem, it can be seen from this, is largely a problem of housing the negro whose income is exceptionally low. Less than one-fourth of the negro population pay as much as \$2 a week rent. If \$5 or \$6 a room per month is the rental set for the federal housing projects, then the zone from which occupants of these two projects will be drawn will undoubtedly be somewhere near as shown on Chart I, *i.e.*, in the neighborhood of the 54 per cent line. The public health need, however, for subsidized housing is greatest in the bottom section of the bar where housing conditions are worst.

CHART I—Rent Classification Based on
Housing Survey of Memphis,
1933-1934

This is where the rents collected are the lowest, since the people living here are the poorest. In addition, the enforcement agency can best handle, in fact, can only handle the problem for permanent and effective results in the top section of the slums.

Chart II using the 1936-1937 figures, outlines a rental classification of 118,142 people with the survey estimated as approximately 80 per cent completed. This represents approximately 30,000 dwellings. It can be seen that the average rent paid by the three lowest classifications which is 66 per cent of the estimated 50 per cent of the population who live in the substandard areas is less than \$3 per room per month.

The rental zone for the federal housing projects is shown as just above the 50 per cent line, since rentals in the federal projects are expected to be in the \$5 and \$6 per room per month class. As pointed out in the discussion of Chart I the greatest public health need is in the bottom section of the bar or population where housing conditions are worst. Here the rents are lowest because the occupants are poorest.

It should be evident, therefore, that publicly subsidized housing and enforcement programs are both working on the same group and, if an energetic publicly subsidized housing program is carried on, the housing enforcement agency will probably have to withdraw from its program. The drawing or fear of drawing the cream of the paying tenants away from private owners of houses catering to this group will make it almost impossible to get their cooperation because of what will be referred to as unfair competition. The Department of Health will then have to and probably should confine its activities to alleviating complaints as best it can and carrying on a generally admitted impossible, ineffective, educational campaign of teaching slum dwellers to live healthfully without ade-

quate and satisfactory sanitary facilities. It may be said here that this paper should in no way be considered as criticism of the two federal housing projects in Memphis, but as pointing to the great need for housing for the "forgotten children" of families unable to pay an economic rent and living under the worst conditions of insanitation and dilapidation.

COÖPERATIVE PROGRAM DESIRABLE

On the other hand, a coöperative program would seem to promise the most rapid and effective housing program that could be devised. The enforcement agencies could concentrate on the top section or blighted areas of the slums and work down the scale as far as possible, requiring minimum standards in these better sections of the slums where rents are paid and condemning all dilapidated and non-conforming houses. Then the publicly subsidized housing program could supply houses for the group that pay almost no rent, for those on relief, or for

CHART II—Rent Classification Based on Survey of Substandard Housing Areas of Memphis, 1936-1937

those who can pay only at times. Publicly subsidized housing could have as its goal, then, the lowest 5, or 10, or even 15 per cent without worrying about this "illusive sharply dividing line which obviously cannot be determined." The dividing line in the lowest 15 per cent can be taken as zero and would be a logical base line from which to start developing a publicly subsidized housing program. It seems entirely possible then for the enforcement agency to start at the top of this slum dwelling group, let us say 30 per cent of our population, and by working down the scale could actually force minimum standards to be met by some 10 or possibly 15 per cent of our population, so that the enforcement program would meet the publicly subsidized housing program half-way between the upper and lower lines.

HOUSING FOR RELIEF WORKERS

The second of the last two housing studies in Memphis was made of the Works Progress Administration work relief rolls and the general direct relief rolls as of June, 1937. It was found that approximately 80 per cent of these WPA clients and 86 per cent of the general direct relief clients, including both white and colored, live in the slums of Memphis. This statement is based on the fact that they live in blocks which rate less than 80 per cent of a minimum standard for decent housing as determined by the Department of Health.² It should be pointed out here that the Memphis Health Department minimum standard, which is the standard referred to throughout this discussion, is considerably lower than the federal public housing minimum standard. The Memphis Health Department minimum is possibly lower than the average citizen would consider essential to decent living. It does not include electric lighting or gas connections, running hot water, any system

of heating except flues so located that the occupant can install stoves and have flues for proper venting. It also does not include a bathtub and other items included in the present publicly subsidized housing projects. The results of the study are summarized in Table II.

It may be pointed out that although a high per cent of both white and colored people on work relief live in the poorest types of housing, the per cent of colored living in the two lowest groups is almost 3 times the per cent of whites living in the same types of housing. This trend continues in the group on direct relief although the difference in the per cent falling in the lowest classes between colored and whites is not as great. The rates of both white and colored on direct relief in the groups living under the worst housing conditions are approximately 5 points higher than the same groups on work relief.

HOUSING FOR RELIEF CLIENTS IMPORTANT

Of course, the question may arise in the minds of many as to whether we will always have people on relief. No doubt the relief load will vary considerably, with a minimum load during good times and a maximum load during depression. It is possible, therefore, that for the very lowest group or for the relief group the present program of publicly subsidized housing is not the solution. Nevertheless, from a public health standpoint, this is the most important group to be provided for, and unless the present program is changed considerably the Department of Health will be hindered rather than helped in its effort to provide better sanitary conditions for slum dwellers.

It might be found desirable to see to it that those on relief be furnished minimum standard housing as a part of their relief through government lease-

† 100 per cent of the families on the rolls surveyed.

ing of approved, privately owned houses. This method would result in much repair and improvement work both on the houses and in the spacing of groups of houses. An added advantage in this plan would be the elasticity of leasing the number needed to care for the relief load. As the clients leave for private employment, the demand for private houses increases and the need for leased houses decreases. Another

problem at this bottom section of the slum may be the mentally deficient ones or families in which the breadwinner is worthless, shiftless, lazy, given to drunkenness, and otherwise unfit to provide for the family. Some type of institutionally directed self-supporting project may be the answer to this problem.

There are in every city—and Philadelphia is no exception—many families who have be-

come so degraded they do not know how to live in a hygienic way. There are problem families who need case work treatment. Nine out of 10 families will respond to good housing, but no amount of good housing will lift others out of the depth into which they have fallen. Some are mental cases, some health cases, some are degenerates. They would bring even good houses down to the level of the slum houses. For the sake of society they must be reclaimed or segregated under municipal control. Until they and others less subnormal who persistently practice sloppy living are forcibly restrained from fouling the houses they occupy, they will continue to make slums. Such families should be subjected to the compulsion of instructive inspection, and when such educational approach proves inadequate they should be removed to municipal colonies, forced to labor in the open, given medical and social treatment, and be allowed to leave such control only when they have demonstrated they can so maintain hygienic living that they will not be a menace to society.³

These suggestions are made to indicate possibilities rather than to attempt to solve a most difficult problem. The solution of this, however, is most important from a public health point of view and if not definitely included in the housing program, will discourage public health workers in trying to realize any benefits, and, it would seem, will take from the housing program most of the public health arguments used to justify it.

PRESENT GOVERNMENT HOUSING SUCCEEDS OR FAILS IN ITS OBJECTIVES

If the present publicly subsidized housing program is designed to help the man who has a house to live in that does not leak, has a private toilet and running water, has screens and windows, etc., but who lacks hot water or steam heat, plenty of yard space and grass and flowers, gas, mechanical refrigeration, and other necessities for an abundant living, at a reasonably low cost, then it has been successful in achieving that goal.

If, however, the publicly subsidized housing program was designed partly at least to improve the sanitary conditions for people living without private toilets, without running water, without screens and windows, with leaking roofs, etc., then the program to date is a partial failure.

As worked out to date, it is providing a more abundant living for the low wage earner who is able to have a decent sanitary home without many conveniences only through sacrificing, but does nothing for the man or his children who live in a dilapidated, insanitary, poorly maintained house.

OBSERVATIONS AND CONCLUSIONS

1. The solution to the problem of providing decent and sanitary homes for the lowest income group is many sided, with poverty standing out as the prime underlying cause.

2. The contention that building houses for the middle class in order to help people in the slums is fallacious in Memphis.

3. The poorest people must of necessity live in the poorest houses and wherever the poorest people live they will sooner or later produce the poorest houses because of the inevitable lack of sufficient funds to maintain the minimum requirements. It may be conversely expressed as "any raising of the standard of existing housing must be followed by a corresponding increase in rents if the improvements are to be permanent."

4. The owners of slum dwellings maintain these dwellings under existing conditions, in general, in as sanitary and as decent a state of repair as is justified by the low rent collected.

5. The Department of Health, as the enforcement agency, can work on the top rental section of the slum dwellers, which is the same section that publicly subsidized housing projects are designed for. A coöperative program with publicly subsidized housing projects working on the lowest group and with the enforcement agencies working on the top group of slum dwellers, is desirable.

6. Poverty and relief are very closely associated, but people falling in these classifications are not eligible for housing in federal housing projects and are not amenable to improvement of housing standards through enforcement. There is no agency or program

now directed toward the relief of this group in the way of providing them with decent sanitary housing.

7. Eighty per cent of the people on work relief and 86 per cent of the people on direct relief live in the slums of Memphis.

8. Unless the publicly subsidized housing programs are redesigned or expanded in order to supply decent sanitary housing for people in the worst sections of the slums, the program will not enlist or deserve the continuing active support of public health departments, or officials even though they will surely not oppose it.

9. If subsidized housing does not include the lowest 10 per cent, then health departments can only attempt the impossible process of trying to educate slum dwellers to live healthfully in the slums without adequate or properly maintained sanitary facilities.

Medical Writing

"IT is, indeed, a pity that this golden age of medicine does not coincide with the golden age of literature. Many important facts and ideas are buried, or at least in part concealed, by verbose or clumsy or otherwise inferior writing. In this matter the early education and environment of the doctor are often at fault. Not only has much of the fundamental cultural training of the youth been neglected, but even the rudiments of penmanship, spelling, grammar, and literary style are often too hastily covered to establish good habits in the student of the present generation. It has become almost a commonplace that the average doctor writes illegibly, spells atrociously, constructs barbaric sentences and paragraphs, and has an uncouth literary style. Since it is impossible to tell in childhood who will be the writers of medicine in the next

generation, it would be wise to require of applicants for admission to the medical schools in the future a truly classical as well as a scientific fundamental education. The inclusion of Greek and Latin in language and literature, French and German, English in all its aspects, and history and archaeology in the pre-medical curriculum might easily make the difference between enjoyment and profit on the one hand and disappointment and neglect on the other, both in the reading and in the writing of important medical scientific papers and treatises. More and more we shall realize the truth of this, and shall strive to emerge from the barbarism of the medical literature of today to a higher level." — Gerrish Memorial Lecture: *Doctors and Books.* *New England J. Med.*, 218:338-343 (Feb. 24), 1938; *J. Assoc. Am. Med. Colleges*, May, 1938.

The Epidemiology of Trichinosis*

C. D. BARRETT, M.D., F.A.P.H.A., AND RICHARD SEARS, M.D.

*Director, Bureau of Communicable Diseases; and Field Epidemiologist,
State Department of Health, Lansing, Mich.*

WORK done by recent investigators places squarely before public health workers the question—Is trichinosis a serious public health problem, and if so, what can we do about it? The data submitted in this paper do not answer either of these questions, but we hope they show some of the intricacies of the problem and throw some light on what needs to be done and what information needs to be assembled.

Hall and Collins¹ have reported that in a group of 1,778 autopsies which they believe constitutes a fairly composite sample of American people, not less than 12½ per cent showed infestation with trichina. Dr. C. V. Weller, pathologist at the University of Michigan Hospital, recently informed us in a personal communication that from the first 25 examinations made, using a 50 gm. diaphragm digestion method advised by McCoy,² he found 5 positive for trichinosis, while, in the second 25 no positives were found. Dr. Weller is continuing his study in order to have a larger group on which to base conclusions.

The writers' interest in trichinosis has been stimulated by discovery, within a year, of 2 relatively large outbreaks, the first in the vicinity of Rogers City, Mich., during January

and February, 1936, for which we have histories for 32 cases; the second in Capac, Mich., for the most part in December, 1936, and for this we have data for 72 cases. Capac and Rogers City are approximately 200 miles apart and have nothing in common other than that they are small towns in rural areas in Michigan. The distance of these towns from our office and the lack of hospitalization have made it difficult to study the outbreaks as thoroughly as desired.

The Rogers City outbreak occurred among a few related families and their friends, who ate sausage prepared on a farm, the owner of which was father or grandfather to most of the cases. Three of the families involved visited the "old folks" and all but 2 persons ate uncooked smoked sausage. These were the only 2 who escaped illness. Although unfortunately no eosinophil counts were made, clinical symptoms in all individuals diagnosed were quite typical. Diagnosis was confirmed by finding the organism in a sample of the sausage in question.

In the Capac outbreak we have been able to make a more complete study. Detailed histories have been obtained, based on several interviews of each case. Eosinophil counts were secured on the majority of cases from 1 to 3 months after onset. Intradermal tests as proposed by Bachman³ were made on the majority approximately 8 months

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

after onset. Diagnosis was confirmed on 2 cases by autopsy specimens. The diagnoses were well established in all but 2 or 3 cases. Tables have been compiled showing these data for the Capac outbreak.

The town of Capac consists of about 800 people. It is the trading center for a rural population of some 2,000 or

3,000. The fresh meat supply is almost entirely distributed through 2 retail stores, both securing their pork and beef from local farmers.

Table I shows data concerning pork eaten by those who became ill and by other members of the household. Table II gives information concerning the hogs marketed in Capac during the

* Dealer Y had no record of number of hogs purchased from each farmer but "usually bought a hog at a time."

month preceding the outbreak. A study of these data indicates that the pork causing the trouble was that handled by Dealer X, who sold perhaps 75 per cent of the pork consumed in Capac. Of the 72 cases, 65 gave a history of having eaten some kind of pork from Dealer X during the month preceding onset. Three stated that they had had pork only from Dealer Y. Some maintained that they had not eaten pork at any time for one month preceding onset. Sixty-one of the 72 cases ate sausage and 12 of these admit having eaten raw sausage; 12 are uncertain as to how well the sausage was cooked, while 37 housewives who cooked the sausage contended it was well done. Two members of Dealer X's family were cases, likewise 2 members of the family of a man who had a financial interest in Dealer Y's business and, therefore, customarily bought meat from him but who on one occasion bought X's sausage.

In Table III are listed the 45 families in Capac having one or more cases. In these households there were 72 or 73 individuals with trichinosis and 93 or 94 persons who escaped any noticeable symptoms. Eighteen of the 94 were skin tested and all found negative to 1:10,000 antigen. Of the 45 families there were 32 with 1 case only, and of these 32, 19 were females who may have tasted sausage in its preparation. A comparison of the 94 well individuals (Table I) in these households shows a lower percentage of them having pork or sausage than of those who were cases. None of the well individuals admit eating raw sausage and only a few were not sure that it was well cooked.

REASON FOR CAPAC OUTBREAK

The Capac outbreak was an unusually large one, but the exact source or reason for the outbreak is not evident. A study of the chronological

the second October 8. The third case with recorded onset of October 15, is of uncertain onset and questionable diagnosis. The first 2 cases are definite but cannot be accounted for as a part of the outbreak proper, the first of which may be said to be that with onset November 30.

Hogs killed and marketed during November and perhaps December must account for the majority of cases. The hog purchased by Dealer X on Novem-

ber 15 from Farmer D (see Table II) was a sow of considerable age and size and was made entirely into sausage. Perhaps this one animal accounts for most or all of the cases following that date. Those cases preceding this time may be the normal sporadic incidence common to such communities. The outbreak occurred in two waves with an intermission of several days which is unexplainable. The sausage made from this one hog probably was the

main supply sold in Capac during a period of several weeks beginning near the end of November.

CLINICAL SYMPTOMS AND SEVERITY OF CASE

The cases in the Capac outbreak have been analyzed as to clinical symptoms and in Table IV-A the different combinations of these symptoms is shown together with degree of eosinophilia. Not always is the "text-book picture" present, namely, gastrointestinal symptoms, edema and muscle pains. When gastrointestinal symptoms are present they do not always precede other symptoms.

Six of the 72 cases were fatal. Thirty-five of the non-fatal cases gave histories of diarrhea, the duration of which for 9 was less than a week, for 15 over 2

weeks, and for 8 over 4 weeks. In 48 cases there were muscle pains and in 20 of these such pains lasted for over 2 months. There was edema present in 46 cases lasting for less than 1 week in 18, and more than 2 weeks in 11 cases. Fifty-five of the 66 non-fatal cases spent time in bed due to illness, and for only 7 of these was this time less than 1 week. In 17 cases the time in bed exceeded 1 month. Fifty-three cases were in persons employed, including housewives, and of these 46 lost more than 4 weeks' work because of illness. In only 2 cases was the time lost from work less than 1 week (see Table V).

We were struck by the many complications and serious debility following the acute symptoms. Because of inability to follow closely each case

TABLE V—(Capac Outbreak)

Severity of Cases

*Number of cases according to duration of symptoms, time in bed, and time off work
(Including only those cases for which data are complete) **

	2-6 1 Day	1-2 Days	2-3 Wks.	3-4 Wks.	4-5 Wks.	5-6 Wks.	6-8 Wks.	2-3 Mos.	3 Mos. Plus	Total

Time off work	0	2	0	2	3	15	5	4	10	54

* Not including six fatal cases

we were able to tabulate in Table VI only what we believe is a very incomplete list of such complications. Eight months after onset it was common to find individuals who could not do their work because of lack of physical endurance. In a number of cases, a heart which may have been abnormal before the trichinosis, did not develop decompensation until afterward. Nervous instability occurred frequently, some patients trying to express this by saying, "I feel I can't hold myself, I just want to fly to pieces." In one instance the father of a case thought his daughter was becoming insane. On the basis of duration of symptoms and loss of time from work we have arbitrarily grouped the 72 cases as to severity as follows:

TABLE VI—(Capac Outbreak)

*Cases with Symptoms or Complications in
Addition to Diarrhea, Edema or
Muscular Pains (Partial List)*

Special senses affected	2
Symptoms suggesting involvement of central nervous system	4

* One case ruptured appendix

6 fatal, 33 severe, 20 moderate, 13 mild.

EOSINOPHILIA

We believe the eosinophil count to be the most useful laboratory aid to diagnosis—during the early stages. Although not always diagnostic it probably would be so in a very high percentage of cases if blood smears were made at frequent intervals from onset throughout the acute illness. However, severe cases may have a low count. The time after onset when the blood smear is taken is a factor in the degree of the eosinophilia found. Table VII, although giving few data, tends to indicate that the eosinophilia decreases 5 or 6 weeks after onset. In Table IV-A we have attempted to show a relation of degree of the eosinophilia to symptoms, in Table IV-B to severity of case, and in Table IV-C according to time after onset. There is also shown a control group, Table IV-D, of eosinophil counts taken from a random sample of the population of Capac excluding households having cases. Data in Table IV-C confirms that in Table VII indicating a slight rise in the degree of eosinophilia from first to fourth week. There was no apparent association of the eosinophilia with any particular symptom nor did the severity of the case appear to coincide with the degree of the eosinophilia.

TABLE VII—(Capac Outbreak)

INTRADERMAL TESTS

Skin tests were used on 74 cases occurring in Rogers City and Capac as well as on a number of other cases and controls. Our antigen was prepared in the laboratory of the Michigan Department of Health by C. B. Line, veterinary pathologist. The method of preparation was a slight modification of that used by Bachman.⁴ The antigen was diluted to 1:500 and 1:10,000, and a control solution was made, using the same diluent without the antigen. Tests were made on 38 Capac individuals as controls who at the time presumably had no clinical evidence of trichinosis. Of the 38 there were 28 negatives, 1 doubtful, 3 mild positives, and 6 pronounced positives.* On rechecking, however, it was found that at least 3 of the pronounced positives and 1 of the mild positives definitely had clinical symptoms attributable to trichinosis. Twenty-one of the Rogers City cases were tested with the 1:10,000

dilution 18 months after the onset, and 17 were found positive. Fifty-four individuals in the Capac outbreak have thus far been tested with the 1:10,000 dilution, about 8 months after onset. All tests were observed for a minimum of 20 minutes. A few of those negative to 1:10,000 were retested with 1:500. The results of the 54 tests according to degree of reaction and clinical severity of case and according to eosinophilia are given in Tables VIII and IX. The few individuals found to be negative or doubtful reactors to the 1:10,000 dilution, and who were retested to 1:500 are indicated. There may be some relation between severity of clinical symptoms and degree of sensitivity to the protein of the organisms as measured by the skin test. More data on this point are needed. Sufficient time has not elapsed for our tested cases to be of value as an indication of duration of sensitivity to the trichina antigen. Thieler,⁷ Augustine, and Spink⁵ found 5 out of 7 cases positive up to 7 years after infestation while Heathman⁶ found 7 persons negative 6 to 10 years after infestation. It is important to know whether, many years after a clinical case of trichinosis,

* Our classification was as follows: Reactions showing 1 cm. or more of edema together with 2 cm. or more of erythema have been called pronounced, those with 0.5 to 1.0 cm. of edema with more or less erythema as mild, and those with any reaction less than this but differing from the control as doubtful.

TABLE VIII—(Capac Outbreak)
Degree of Skin Reaction in Relation to Severity of Case
 (Antigen diluted 1-10,000)-

<i>Degree of Reaction</i>	<i>Number of Cases According to Severity of Symptoms</i>			
	<i>Mild</i>	<i>Moderate</i>	<i>Severe</i>	<i>Total</i>
Negative	2	3	1	6
Doubtful	0	0	1	1
Mild positive	3	3	6	12
Pronounced positive	4 *	12 †	19	35
Total	9	18	27	54

* This number includes 1 case which did not react to the 1-10,000 dilution but gave a pronounced reaction to the 1-500 dilution.

† This includes 2 cases one of which gave a negative reaction and the other a doubtful reaction to the 1-10,000 dilution, but both gave a pronounced reaction to the 1-500 dilution.

the sensitivity to the antigen may be measured by the skin test or perhaps with the blood precipitin tests as proposed also by Bachman. We have done only 6 blood precipitin tests of which 2 were positive, these 6 having been positive to the intradermal test. The skin test is the more convenient procedure of the two. It usually becomes positive about 2 to 4 weeks after onset. This has been confirmed by McCoy, Miller, and Friedlander⁷ and Spink and Augustine.⁸

In Table IX has been assembled data showing degree of eosinophilia together with degree of reaction to the skin test. In 1 case with 3 per cent or less eosinophils there was a pronounced re-

action to a 1:10,000 dilution of antigen. Seven cases with an eosinophil count of from 4 to 9 per cent showed a pronounced skin reaction. Of these 7, 2 were first found negative to a 1:10,000 dilution and pronounced positives only to the 1:500 antigen. The other 5 showed pronounced reactions to the 1:10,000 dilution.

On the other hand, there were 4 with eosinophil counts in the group of 10 to 29 per cent which were negative to the 1:10,000 dilution, and 1 which was re-tested and found negative to a 1:500 dilution. All of those with very high eosinophil counts gave pronounced reactions to the 1:10,000 dilution.

Most of the eosinophil counts were

made from 4 to 6 weeks after the onset, while the skin tests were made approximately 8 months after.

INCUBATION PERIOD

In 25 of our cases we were able to determine with a fair degree of accuracy the date on which the sausage was eaten and the date on which first symptoms were noted. The mean incubation period for these 25 cases was 9.1 days, the median was 7 days. The longest incubation period was 17 days and the shortest 2 days. There were 4 persons in one family who ate sausage on the same day, 2 of whom definitely noted gastrointestinal disturbances 48 hours later; the other 2 after 7 and 12 days. For those cases other than the 25 already mentioned it was more difficult to ascertain the time of infestation or a definite onset, but it was certain that some of them had longer periods of incubation than 17 days. One case had an incubation period of not less than 30 days, possibly 35. Drake, Hawkes, and Warren⁹ have determined the incubation period in 14 cases as varying from 4 to 27 days.

NATIONALITY

The question of nationality and food habits is often referred to in considera-

tion of outbreaks of trichinosis. Hall¹⁰ contends that in the United States most cases occur among Americans not of German descent although he admits the attack rate may be higher among Germans. In Rogers City all the 32 cases were of German descent. In Table X we have classified the Capac cases as to nationality, considering all of those as Americans whose parents were born in this country. It will be noted that more than 50 per cent were German on the basis of this classification and it may be further stated that 22 of those listed as American were of German descent of the third or fourth generation. Germans appear to have a liking for smoked, raw or rare sausage. On the basis of our experience, this dietary habit is the cause of higher incidence among these people.

SEX, AGE, AND OCCUPATION

The Capac cases are classified as to sex and age in Table XI and as to occupation in Table XII. Also in Table XI is given classification as to sex and age of well individuals in households with cases. There is perhaps no particular susceptibility of either sex or any age group. Perhaps men eat more meat and more sausage. If so, this is offset by the fact that women who are

preparing meals often taste the raw sausage for seasoning. Children appear to have milder cases and in the Capac outbreak there was a somewhat greater number of those under 20 in households with cases who escaped having the disease than of the older ages. May this not be due to the fact that parents discourage eating of much sausage by children? Occupation appears to have had no significance in the Capac cases.

GENERAL INCIDENCE

Little is known at present as to the real incidence of trichinosis. Relatively very few cases are diagnosed and officially reported to health departments. Aldridge¹¹ could find, as officially reported cases, in all state health departments a total of 1,550 cases from 1842 to 1914. The *Public Health Reports* have listed for 1930–1934 inclusive a total of 1,480 cases occurring in 21 different states, for the year 1935, 591 cases in 18 states, and for the year 1936, 297 cases in 13 states. Mild clinical cases may be difficult to recognize but from our experience we believe physicians should diagnose without much difficulty such cases as constituted the majority in the two outbreaks we have reported. Prolonged diarrhea particularly with a greenish stool which cannot be otherwise accounted for should always call for an eosinophil count. Likewise, cases with muscle tenderness and pain should have an eosinophil count. It is true that many physicians are not aware that the trichinosis case should be reported. We have discovered recently quite by chance 3 cases in a

Lansing hospital and since we have been interested in this disease, quite a number of cases have come to our attention.

IMMUNITY

There is little evidence as yet to show whether humans develop an immunity to trichinosis as a result of small and repeated infestations. McCoy² claims some experimental immunity in rats. Swartz¹² maintains that one attack of the disease does not confer immunity. If there is such a thing as immunity this would tend to explain the large number of infestations found in autopsies and the relatively small number of cases diagnosed during life. During our investigation in Capac a few individuals were found who showed either a high eosinophil count or a positive antigen skin test, or both, but who had no ascertainable symptoms.

INCIDENCE IN HOGS

In consideration of the problem of human trichinosis, study must be given to the incidence among hogs. No doubt infestation varies greatly according to locality and to manner of feeding. One hundred examinations of pig diaphragms made in the laboratory of the Michigan Department of Health were all found negative. Fifteen of these were fed on slaughterhouse offal. Ninety-four examinations of diaphragm tissue of farm hogs were made recently by Dr. William Thorpe and Hans Ruhland of the Department of Animal Pathology of Michigan State College and all found negative.

Hall¹³ has collected data indicating that about 1 to 1.5 per cent infestation

exists in grain fed hogs for the country as a whole, and 3 to 5 times that much in garbage fed hogs. Hall outlines a suggested control program for human trichinosis based largely on restrictions of garbage feeding of hogs.

REMARKS AND SUGGESTIONS

It is the hope of the writers to continue the study of trichinosis, particularly as to endemic incidence and the amount of human disability the disease may cause. We believe our data thus far will help to reveal the significance of the antigen skin test and the eosinophil count, to add to our knowledge of the symptomatology. There are given the epidemiological characteristics of two large outbreaks. We make no other conclusions but desire to offer a few remarks and some suggestions based on a study of the literature and our own experiences.

1. *Incidence of Infestation*—Further work should be carried on in the study of autopsy material to determine the incidence of human infestation in various parts of the country. Figures presented thus far by various workers indicating 10 to 15 per cent infestation need to be corroborated. Pathologists may perhaps collect data as to degree of infestation and this may be correlated with any evidence of clinical symptoms during the life of the individual.

2. *Clinical incidence*—The clinical incidence as manifested by cases with more or less severe attacks incapacitating the individual for a time and perhaps leaving permanent disability may be far less than the percentage of individuals infested as shown by autopsy studies. Certainly the percentage of such cases is, however, greater than that which is known at present. The help of various public health workers is needed to determine the real incidence of clinical trichinosis.

a. The Practising Physician—Physicians should be informed that trichinosis may be quite common. They should be instructed as to the symptoms of trichinosis and its many manifestations. If one is on the alert the average case should not be particularly difficult to recognize. The eosinophil count is not used frequently enough. Diagnosed cases should be officially reported.

b. The Health Officer—The health officer should publicize the disease using the utmost conservatism to avoid arousing the undue fear of the public. He should collect all reports and epidemiological data concerning cases and outbreaks, ask that eosinophil counts be made, and have intradermal tests performed.

c. The Laboratory Research Worker—It is at present difficult to secure reliable trichina antigen. Some standardization is needed, also further work to show the significance and possibilities of the intradermal and precipitin tests.

d. Epidemiologists—Epidemiologists should assemble and analyze data collected by local health officers. They may also make group studies on different samples of population using the intradermal and precipitin test. They can correlate data as to incidence among hogs, and finally from all of the facts attempt conclusions.

3. *Incidence in Hogs*—Veterinary-pathologists and departments of agriculture should collaborate in the study of trichinosis by determining more completely the incidence among hogs in various parts of the country; likewise for hogs according to manner of feeding.

4. *Control*—Only if the above questions have been answered can the real solution to control be known. It may be one of control of the garbage fed hog or it may be education of the public as to the danger of raw or partially cooked pork. Perhaps such education should be directed especially to those persons with dietary habits peculiar to certain nationalities.

CONCLUSIONS

The problem of trichinosis has been reopened by data recently assembled. It requires further study. Trichinosis may be a public health problem of considerable magnitude. It cannot be dismissed as a "rare disease."

Legislative Enactments in the Province of Ontario

THE following items are supplied to the *Journal* by B. T. McGhie, M.D., Deputy Minister of Health and Hospitals of the Ontario Department of Health:

The sale of unpasteurized milk in any city or town in Ontario is prohibited by an amendment to The Public Health Act. This legislation can be extended to other areas of the Province from time to time by Order-in-Council.

Authority has been given to the department to make regulations for the qualifications of medical officers of health. An act provides that a medical officer shall cease to hold office at 70 years, unless the municipal council with the approval of the Minister continues him in office from year to year to the age of 75.

Wide powers are given to the local health authorities to deal with typhoid and paratyphoid carriers. When a person is deprived of his means of livelihood by reason of an order of a med-

ical officer of health, the Province will pay him compensation, the amount to be determined by regulations.

A Cancer Remedy Act has been enacted providing for the appointment of a commission by the Government of Ontario with power to require any person in the Province to submit to the commission any substance or method of treatment used for cancer. The commission may thereupon investigate the merits of the remedy and may issue a public report of its findings.

Far-reaching changes have been made in the system of financing tuberculosis sanatoria. These were formerly maintained by municipal and provincial grants for each needy patient. Municipal liability has now been abolished and the total cost will be defrayed by the Province. It is expected that as a result there will no longer be any financial restraint upon the admission to hospitals of persons suffering from tuberculosis.

Nutrition Program in a State Health Department*

WOODBRIIDGE E. MORRIS, M.D.

Director, Division of Maternal and Child Health, State Board of Health, Dover, Del.

A PROGRAM of public education in the dietary improvement of health was conducted during the 1936-1937 school year in Kent County by the Delaware State Board of Health, in coöperation with the State Board of Education and the State Extension Service in Agriculture and Home Economics. Credit for its execution should go in large measure to the enterprise, ability, and enthusiasm of Pearl MacDonald, State Nutritionist, whose services we were enabled to share on a half-time basis by the generosity of the University of Delaware. I wish here to express our gratitude to those whose previous efforts in this field have stimulated and guided ours. I present this account to you with the hope that our organization, methods, and experiences may have some practical value to others who contemplate, or who are engaged in similar undertakings.

Let me tell you first what we did, then how we did it, and finally why we did it.

Kent County was chosen for the demonstration for several reasons. With a population of 32,000, it contains only 4 communities which might

be termed towns, or a total urban population of perhaps 9,000. It has 20 per cent negro population, the highest in the state. The death rates, except that for diphtheria, are generally higher in this than in the other counties. The 1933 maternal mortality was 168, the infant mortality was 81, the tuberculosis rate was 101. For this same year, the state maternal mortality rate was 61, the infant mortality rate 66, the tuberculosis rate 64.

Our objective was to make people realize the value of adequate nutrition to their children. The public was reached through posters, news stories, meetings, demonstrations, and circular letters to the parents of school children.

The posters used were a series obtained from the National Dairy Council, which kindly consented to our changing the verses so as to emphasize the protective foods. The news stories were printed in the Wilmington daily papers (the only dailies reaching the area) and in the weeklies issued in the county.

Seventy-two meetings were held—with parents in schoolhouses, with teachers or principals or both at these or at special conferences, and with Home Demonstration clubs, Parent-Teacher Associations, women's clubs, men's service groups, and granges (Pomona and subordinate). Through

* Read at a Joint Session of the Child Hygiene, Food and Nutrition, and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

these, the key people of the county were reached. That they were interested was indicated by the scores of questions they asked.

May I mention here a mistake I think we made in these meetings. We did not serve refreshments. Where they were on the program anyhow, attendance was nearly always much greater. A mistake we avoided was sending people away altogether empty-handed; mimeographed sheets were given out on the importance of good foods and on ways to prepare them in attractive variety. Each person was asked to take two or three of these home, to give to the neighbor who could not come.

In demonstrations, we reinforced the effort which the Home Demonstration Clubs have been making for some years. Miss MacDonald held a special leader-training meeting on Better Breakfasts for Children. The 30 who attended gave demonstrations, in turn, to 364 women in the 23 clubs of the county. In one club, every member "adopted" a young mother in the neighborhood and passed on to her nutrition information given at the meetings.

Apart from the state-wide breakfast survey which I shall describe, 260 Home Demonstration Club members conducted a home breakfast study of their own, on 651 adults and 256 children. It showed them that too little milk, fresh fruit, eggs, and whole grain products were used.

The Parent-Teacher Associations arranged garden-planning and canning meetings in 29 communities. Twelve were colored groups. Total attendance was 537. Six groups agreed to can extra vegetables to be used this year for a hot dish for the school children's lunch.

A hot dish for lunch was served at twelve one-room and two-room schools where it had not been attempted before. In the larger schools, having

cafeterias and a special school nurse, Miss MacDonald coöperated by helping the children to select good food for their money.

The principal of one small school bought four young rats for the children to feed, one pair on meat and potatoes; the other pair on fruit, vegetables, and milk as well.

Our fifth method of reaching people was by the circular letters to 4,400 families having children in school. There is no school census in Kent County. Accordingly, blank State Board of Health envelopes were taken by each district public health nurse to every school in her district. The teachers were asked to hold a letter addressing class. Each child practised writing the name and address of his parents, and finally wrote it on the envelope. The envelopes were collected by the teachers, and brought in to our central office by the nurse. The resulting mailing list proved 99 per cent accurate. The first letter was sent in the very envelope, franked by the state, which bore the child's handwriting.

Four letters were sent out during the year to this list. They were worded simply, and they reached the people who did not attend the meetings. The first stated what good food will do for the school child's health, happiness, and success. It ended: "The best breakfast, for the school child, is child-sized amounts of fruit, cereal, egg or bacon, milk, bread or toast. The school lunch should include one hot dish." It was signed by the State Superintendent of Public Instruction and the Executive Secretary of the State Board of Health.

The second letter enclosed duplicates of the mimeographed sheets handed out at the meetings, and repeated the reasons for giving children the protective foods. The third, signed by the County Agricultural Agent, advocated a year-round home vegetable garden, stated its money value, listed the kind

and cost of seed to be used, and told to whom to write for assistance with details. No direct check has been attempted on the effect of this, because an adequate one was not thought possible.

The fourth mailing was of a booklet, *Thought for Food*. It contained ten different inexpensive breakfasts, the costs and contents of several "pattern" breakfasts, dinners, and suppers, and a specific "Food Cost Guide." It was directly aimed to combat the argument so often heard: "We haven't money enough to buy the foods you say we should."

Early in the program a special personal letter was sent to the practising physicians, describing the nature and purpose of the endeavor, and asking their coöperation.

We realized before we started any of this endeavor that our public health nurses were not equipped to handle the field problems which it would plow up. Hence, as our first step, the state nutritionist gave them a special course, providing them with practical material and a working vocabulary for use in the home. Thus they were of real value to teachers and parents. Problem cases they brought to the nutritionist.

Emphasis throughout was laid upon the breakfast because this is believed to be the worst meal, from the nutrition standpoint, among rural people, and because of the physiological importance to the child of a good breakfast. To determine what our situation actually was, before the public education activity started, a survey of 6,511

TABLE I

Survey of Foods Eaten at Breakfast by Delaware School Children

Foods	6,511 White and Colored Pupils		5,308 White Pupils		1,203 Colored Pupils

school children's breakfasts was made by the Dental Hygienists of the State Board of Health. It was done quietly, in the course of their routine conversation with the individual child, apart from the others. We believe it to be as accurate as such a survey could be. A summary of findings is available to you here at this meeting (Table I).

About half these breakfasts were inadequate, either in quality or in kinds of food necessary for good nutrition. For example, 46 per cent contained no cereal, 63 per cent contained no milk apart from that used on the cereal, 82 per cent contained no fruit, and 2 per cent of the children had come to school with no breakfast at all. On the basis of these figures, together with the knowledge of the Extension Service as to other meals, and our physical findings as to the Delaware school child's general and dental condition (e.g. 88 per cent dental caries), we felt justified in telling the people of Delaware that every other school child was probably, to some extent, malnourished.

Fifteen portable scales, furnished by the Delaware Anti-Tuberculosis Society, were distributed to rural schools isolated from stores where scales are available. Food records, as well as weight records, were kept by teacher and pupil. They stimulated the interest of teacher, parent, and child in the child's own health, and in the importance of food with relation to it. Three hundred sixteen pupils enrolled. The food intake for a complete week at the start, as contrasted with a week at the end, showed better breakfasts in one-third of the records through increased use of milk, eggs, and fruit. Teachers said they noticed improvement in health, and with it, improvement in studies and behavior. The veracity of such reports is always open to question, but they may at least be taken to indicate that health ideas were planted.

The axiom upon which this whole program was conducted was: The health of people varies according to the food they eat. We told the public, "The growth of children, their disposition, their posture, the condition of their teeth are all directly affected by the kind of food they eat and the way they live. When children are properly fed, they are better able to resist or throw off sickness. Also, success in their daily school work is conditioned by their daily food."

It should be noted here that this demonstration was made possible through the funds available to Delaware by the Social Security Act, through the Children's Bureau of Washington, and that Kent County was chosen, as the act requires, as a "predominantly rural area, an area of special economic distress."

As the program has proceeded, there has been an attitude of increasing interest in nutrition in relation to health among school authorities, teachers, community groups, and the laity in general. There has been general public amazement at the results of the breakfast survey, particularly at the unexpectedly small differences between the findings among the colored and among the white.

Continuation of the work is planned. It is to be intensified and enlarged, particularly with regard to the school lunch, and is to include another county, where similar health and economic conditions prevail. One method of extending it will be through the training in nutrition of local health chairmen and leaders of local groups, and then inducing them to reach individual families outside of, as well as within, these groups. A second will be through the associations of producers and distributors of the protective foods which their neighbors are too meagerly consuming—the dairymen, poultrymen, canners, vegetable and fruit growers, and

grocers. Delaware can produce enough of the protective foods so that none of her children need suffer from lack of them. We deliberately employ sensationalism and say that Delawareans are half-starving in the midst of plenty.

Results are expected to lag. It is felt that to change the eating habits of a people is nearly as difficult as to change their religion.

On the other hand, we are convinced that a state board of health can do no more fundamental service toward long-run improvement of the health of future generations than to develop an understanding of the value of a good

diet. We believe Dr. Sherman's motto, quoted in the front of our booklet: "An optimum diet would add not only years to one's life, but life to one's years."

SUMMARY

A program of public education in the dietary improvement of health was conducted during the 1936-1937 school year in Kent County, Dela. The public was reached through posters, news stories, meetings, demonstrations, and circular letters. Emphasis was laid on breakfasts. A survey of 6,511 school children's breakfasts showed half to be inadequate.

Beware of Hollandaise Sauce

WITHIN the past few years Hollandaise sauce has been implicated in several outbreaks of food poisoning in Baltimore and elsewhere in the United States. Where investigated it was revealed in many instances that the sauce involved in the outbreaks contained bacteria which were capable of producing the offending toxin. Unlike some other forms of food poisoning it seems that this special type may appear at any season of the year, in warm weather or in cold.

Hollandaise sauce is one of the few

foods that can neither be successfully refrigerated to retard the growth of bacteria nor heated in order to kill off the organisms. This is because refrigeration hardens the butter in the sauce and causes it to become solid, while heating the sauce coagulates the eggs and causes the mixture to become lumpy. In either process the commodity is rendered unsuitable for serving, so that this product needs to be eaten very promptly after it is made. . . . —*Baltimore Health News*, Baltimore Health Department, April, 1938.

A Tabular Outline for Use in Reporting Hospital Morbidity*

JOSEPH BERKSON, M.D., F.A.P.H.A.

*Division of Biometry and Medical Statistics, The Mayo Clinic,
Rochester, Minn.*

ESSENTIAL to any comprehensive system of keeping account of diagnoses in the record rooms of hospitals is provision for a tabular summary of such diagnoses, of the sort that may be made for annual reports. In a previous article¹ I discussed the relationship of this function to other purposes which must be considered, and described a scheme for adapting the whole system to punch cards. Here I shall deal only with an amplification of that part of the subject which deals with the matter of the enumeration of diagnoses in tabular form.

Much discussion of the question of indexing medical diagnoses is needlessly confused because of failure to distinguish between a number of different problems involved. There is, for instance, the consideration of "nomenclature." Whether a pathologic condition should be called "pernicious anemia," "idiopathic anemia," "hyperchromic microcytic anemia," or "Addison's disease"; whether another condition shall be designated "melanotic carcinoma," "melanotic sarcoma" or "melanoma"; whether, "lymphadenitis" is an acceptable term—are all important questions in relation to the science of

nosology. They are not essential, however, if the task is that of enumerating the individuals suffering from those conditions. There is, again, the subject of *classification* of disease, which also is not a central consideration for the systematic enumeration of diagnoses. Classification is a *scientific* enterprise which proceeds in strictly logical fashion according to some defined, descriptive principle (e.g., "anatomic," "etiologic," "symptomatic"). It deals essentially with the abstract concepts of diseases rather than what is observed in individuals who are subject to them. The disease entity "carcinoma" may be logically divisible into the classes adenocarcinoma and epithelioma; and so far as the science of taxonomy is concerned, these two mutually exclusive classes may be exhaustive. But for statistical enumeration, there will have to be a place for patients with the diagnosis of "carcinoma" (*i.e.*, unknown with regard to whether glandular or epithelial) as well as for "neoplasm" (*i.e.*, unknown with regard to whether carcinoma or sarcoma). On the other hand, for purposes of enumeration a single principle in the ordering of the tabular categories is not a *sine qua non*.

These rather elementary observations are made to forestall hundreds of questions that one may hear discussed when the indexing of diagnoses is the subject;

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

but they do *not* concern us here and it will be well to exclude them explicitly from our present consideration.

What we *are* concerned with is the practical problem of providing an outline in terms of which an enumeration of diagnoses can be made and one that will be satisfactory for *statistical* purposes. A list of rubrics which will be satisfactory in that sense should have certain characteristics: (1) The individual rubrics should be sufficiently broad to make possible the assignment of diagnoses, even if not made with great refinement, yet narrow enough to be usefully discriminating. (2) The number of such rubrics or classes should be reasonably short.

Bolduan has discussed the value that a uniform system of reporting hospital morbidity might have for enlightening questions of interest to public health. In the Division of Biometry and Medical Statistics of The Mayo Clinic we have for the last several years struggled with the problem, with the practical objective of providing a tabular outline that would furnish a reasonably simple and consistent statement of the diagnoses made annually. After considerable experimentation we decided to use as a basis for our outline the *International List of Diseases and Causes of Death*,³ for the reason that that set of rubrics has the widest current use for purposes of statistical enumeration.* However, since our aim was to report morbidity, not mortality, it was necessary to modify it. Certain of the entries in the *International List* refer necessarily only to deaths such as "homicide" and "violent deaths." Other entries had to be changed because they were not as clear or specific

as necessary. In still other cases, when the entries of mortality were translated into diagnoses of morbidity there resulted an overlapping of designations. We therefore modified the entries, but in doing this we proceeded on the principle that the original arrangement and designations be disturbed as little as possible, and in each instance only for definite reasons. In this way we hoped to preserve, so far as was possible and consistent with the purposes in hand, the facility of comparing statistics of morbidity with statistics of mortality, as reported in terms of the *International List*. Yet, for our list a rather considerable number of modifications had to be made. We have now used this set of rubrics for the tabulation of the experience of three successive years, and more than 300,000 diagnoses have been assigned according to it. Yet it is not to be considered as a finished product. In response to repeated requests we are publishing this list now and it is to be hoped that it will be tried by a number of representative hospitals. It would be highly desirable if the experiences of different hospitals were accumulated and from the assembled experience a list to be developed which could be adopted as standard.

The set of rubrics is given in Table I, together with code numbers which can be used in a three-column punch card code or which can be translated into a single-column multiple-punch code. It will be noted that unused numbers are interspersed liberally in the code for additional entries. In parentheses to the right of the entries are given the numbers of the *International List*⁴ which correspond to the rubrics of The Mayo Clinic List. Since a number of the classes of the *International List* have been considerably subdivided and rearranged, various of The Mayo Clinic rubrics correspond to particular diagnoses that may be found in several rubrics of the *Inter-*

* Other individuals, I am aware, have made up similar lists. Specifically, Selwyn D. Collins of the U. S. Public Health Service has used a list, which is a modification of the *International List of Causes of Death*, for the summarizing of morbidity surveys. But the List of The Mayo Clinic is specifically adapted to hospital morbidity, and moreover has had a trial for several successive years.

national List. The outline is not, of course, a list of diagnoses but a list of rubrics into which diagnoses are fitted, though in particular places a rubric may correspond to a single specific diagnosis. It is essentially a statistical and practical instrument, not a guide for scientific diagnosis or an authority for proper medical nomenclature. In practical application there

is used in conjunction with the outline of rubrics an index of diagnoses. Here are arranged, alphabetically, detailed diagnoses with the code numbers corresponding to the rubrics to which they belong, and in this index are incorporated decisions as to the disposition of diagnoses which, from a consideration of the outline alone, would be equivocal.

- 083 Syphilis, tertiary, bone (34)
- 084 Syphilis, tertiary, central nervous system, e.c.e. (34)
- 085 Syphilis, tertiary, e.c.e. (34)
- 095 Syphilis, congenital (34)
- 105 Syphilis investigated, serology positive (34)

- 106 Syphilis, e.c.e. (34)
- 112 Gonococcus infection, joints (35)
- 113 Gonococcus infection, genito-urinary organs, male (35)
- 114 Gonococcus infection, genito-urinary organs, female (35)
- 115 Gonococcus infection, eye (35)
- 116 Gonococcus infection, e.c.e. (35)
- 121 Venereal disease, e.c.e. (35)
- 123 Septicemia (36)
- 126 Yellow fever (37)
- 127 Malaria (38)
- 132 Diseases due to protozoal parasites, e.c.e. (39)
- 134 Ankylostomiasis (40)
- 137 Hydatid cysts (41)
- 140 Diseases caused by helminths, e.c.e. (42)
- 141 Actinomycosis (43)
- 145 Mycoses, e.c.e. (43)
- 146 Chickenpox (44a)
- 147 German measles (44b)
- 148 Mumps (44c)
- 152 Infectious and parasitic diseases, e.c.e. (44c)

II. NEOPLASMS

- 154 Neoplasm, malignant, lip, (45)
- 156 Neoplasm, malignant, tongue (45)
- 159 Neoplasm, malignant, salivary glands (45)
- 162 Neoplasm, malignant, buccal cavity and pharynx, e.c.e. (45)
- 165 Neoplasm, malignant, esophagus (46)
- 169 Neoplasm, malignant, stomach (46)
- 172 Neoplasm, malignant, small intestine (46)
- 175 Neoplasm, malignant, large intestine, except rectum (46)
- 177 Neoplasm, malignant, rectum (46)
- 180 Carcinomatosis, abdominal (46)
- 183 Neoplasm, malignant, pancreas (46)
- 185 Neoplasm, malignant, gallbladder and ducts (46)
- 188 Neoplasm, malignant, liver (46)
- 193 Neoplasm, respiratory system (47)
- 196 Neoplasm, malignant, uterus (48)
- 199 Neoplasm, malignant, ovary (49)
- 202 Neoplasm, malignant, genito-urinary organs, female, e.c.e. (49, 53)
- 205 Neoplasm, malignant, breast (50)
- 210 Neoplasm, malignant, testis (51)
- 213 Neoplasm, malignant, prostate (51)
- 216 Neoplasm, malignant, adrenal gland (51, 53)
- 219 Neoplasm, malignant, kidney (51, 53)
- 221 Neoplasm, malignant, bladder (51, 53)
- 224 Neoplasm, malignant, genito-urinary organs, male, e.c.e. (51)
- 227 Neoplasm, malignant, skin, e.c.e. (52)
- 230 Neoplasm, pituitary (51, 54, 55)

* e.c.e. means except elsewhere enumerated.

- 232 Neoplasm, brain, including cranial nerves, e.e.e. (53, 54d, 55d)
 235 Neoplasm, spinal cord (53, 54e, 55e)
 237 Sarcoma, bone, any part of body (53)
 244 Hemangio-endothelioma and Lymphangio-endothelioma, except brain or spinal cord (53)
 247 Neoplasm, malignant, thyroid (53)
 250 Neoplasm, eyeball and orbit (53, 54e, 55e)
 255 Melanocarcinoma, e.e.e. (53)
 257 Neoplasm, malignant, e.e.e. (53)
 263 Fibroma, uterus (54b)
 268 Endometrioma (54b, c)
 271 Polyp, female genital tract (54b, c)
 274 Neoplasm, nonmalignant, abdominal or pelvic, female, e.e.e. (54b, 55b)
 276 Adenoma, prostate (137)
 278 Neoplasm, nonmalignant, skin (54e)
 279 Lipoma (54e)
 281 Hemangioma and lymphangioma (54e)
 287 Neoplasm, nonmalignant, bone (54e)
 290 Neoplasm, nonmalignant, breast (54e)
 295 Polyp, gastro-intestinal tract (54e)
 298 Polyp, nose (54e)
 299 Neoplasm, nonmalignant, respiratory system, e.e.e. (54e)
 300 Von Recklinghausen's disease (neurofibromatosis) (54e)
 303 Neoplasm, nonmalignant, nerve, e.e.e. (54e)
 306 Neoplasm, e.e.e. (53, 54e, 55e)
 310 Neoplasm, follow-up examination

III. RHEUMATIC DISEASES, NUTRITIONAL DISEASES, DISEASES OF THE ENDOCRINE GLANDS, AND OTHER GENERAL DISEASES

- 312 Acute Rheumatic fever (56)
 317 Rheumatism, e.e.e. (57)
 320 Gout (58)
 322 Diabetes mellitus (59)
 325 Diabetes, e.e.e. (69)
 327 Scurvy (60)
 330 Beriberi (61)
 332 Pellagra (62)
 335 Rickets (63)
 340 Acromegaly, without pituitary tumor specified (65)
 342 Hypopituitarism (65)
 345 Diseases of the pituitary body, e.e.e. (65)
 348 Adenoma, toxic, thyroid (66a)
 349 Adenoma, nontoxic, thyroid (66a)
 350 Exophthalmic goiter (66b)
 353 Goiter, e.e.e. (66e)
 355 Myxedema (66c)
 358 Cretinism (66c)
 361 Tetany, parathyroid (66d)
 363 Tetany, e.e.e. (66d)
 366 Diseases of the thyroid and parathyroid glands, e.e.e. (66e)
 371 Addison's disease (31, 68)
 373 Dysfunction, ovarian (139b)
 375 Endocrine disturbances, e.e.e. (69)
 376 Obesity (69)

IV. DISEASES OF THE BLOOD AND BLOOD-MAKING ORGANS

- 377 Purpura (70a)
 380 Hemophilia (70b)
 382 Pernicious anemia (71a)
 388 Anemia, e.e.e. (71b)
 391 Leukemia (72a)
 393 Lymphosarcoma (72b)
 396 Hodgkin's disease (72b)
 399 Banti's disease (73)
 404 Diseases of the spleen, e.e.e. (73)
 407 Polycythemia vera (74)
 410 Agranulocytosis (74)
 413 Diseases of the blood and blood-making organs, e.e.e. (74)

V. POISONINGS AND INTOXICATIONS

- 416 Alcoholism (75)
 418 Poisoning, by inhalation gas (178)
 423 Poisoning, lead (77a)
 425 Poisoning, e.e.e. (77b, c)

VI. DISEASES OF THE NERVOUS SYSTEM AND OF THE ORGANS OF SPECIAL SENSE

- 428 Encephalitis, e.e.e. (78)
 430 Abscess, brain (78)
 433 Meningitis, e.e.e. (18, 79a, b)
 436 Progressive locomotor ataxia (tabes dorsalis) (80)
 439 Charcot joint (80)
 442 Amyotrophic lateral sclerosis and combined sclerosis (81)
 445 Progressive muscular atrophy (81)
 448 Progressive muscular dystrophy (81)
 451 Syringomyelia (not associated with tumor) (81)
 454 Multiple sclerosis (87b)
 457 Friedrich's ataxia (81)
 459 Ataxia, Marie's (81)
 462 Paralysis and other residuals of cerebral hemorrhage (82a)
 466 Paralysis, central nervous system, e.e.e. (87b)
 470 Paralysis, peripheral nerves (87b)
 472 Diseases of the Spinal Cord and Brain, e.e.e. (81)
 475 Aneurysm, brain (96)
 478 Cerebral embolism and thrombosis, acute, e.e.e. (82b)
 481 General paralysis of the insane (83)
 483 Dementia praecox and other psychoses (84, 87b)
 486 Neuroses, minor (functional complaint) (87b)
 489 Epilepsy, except Jacksonian (85)
 491 Trigeminal neuralgia (87a)
 492 Paralysis, facial (82d)
 493 Paralysis, cranial nerves, e.e.e. (82d)
 494 Neuralgia and neuritis, e.e.e. (87a)
 497 Chorea, Huntington's (87b)
 499 Chorea, except Huntington's (87b)
 505 Idiocy (87b)
 507 Migraine (87b)
 511 Diseases of the nervous system, e.e.e. (86, 87b)
 515 Glaucoma (88)
 517 Cataract (88)
 520 Amaurosis (88)
 523 Trachoma (88)
 525 Errors of refraction (88)
 527 Diseases of the organs of vision, e.e.e. (88)
 529 Otitis media (89a)
 530 Deafness (87b, 89a)
 532 Ménière's disease (89a)
 535 Diseases of the ear, e.e.e. (89a)
 538 Diseases of the mastoid process (89b)

VII. DISEASES OF THE CIRCULATORY SYSTEM

- 542 Rheumatic heart disease (56, 92, 93, 95b)
 545 Hypertensive heart disease (95b)
 548 Subacute bacterial endocarditis (92a)
 550 Angina pectoris (94a)
 551 Coronary embolism and thrombosis (94b)
 553 Diseases of the heart, e.e.e. (90, 91, 92, 93, 94, 95)
 555 Vascular aneurysm, e.e.e. (96)
 558 Arteriosclerosis, e.e.e. (97)
 563 Raynaud's disease (98)
 566 Thrombo-angiitis (99)
 568 Diseases of the arteries, e.e.e. (99)
 571 Phlebitis (100)
 573 Hemorrhoids (100)
 576 Varicose veins (100)
 578 Diseases of the veins, e.e.e. (100)
 581 Lymphangitis (101)
 583 Hypertension, essential (102)
 586 Hypertension, e.e.e. (102)
 588 Anomalies of the blood pressure, e.e.e. (102)
 592 Diseases of the Circulatory system, e.e.e. (103)

VIII. DISEASES OF THE RESPIRATORY SYSTEM

- 595 Rhinitis, vasomotor (104a)
- 598 Rhinitis, except vasomotor (104a)
- 601 Diseases of the nasal fossae and annexa, e.e.e. (104)
- 603 Sinusitis (104b)
- 605 Laryngitis (105)
- 608 Diseases of the larynx, e.e.e. (105)
- 610 Bronchitis (106)
- 613 Bronchopneumonia (107a)
- 615 Lobar pneumonia (108)
- 619 Pneumonia, e.e.e. (109)
- 622 Pleurisy (110)
- 624 Pulmonary embolism and thrombosis (111a)
- 627 Pulmonary edema (111b)
- 629 Asthma (112)
- 631 Pulmonary emphysema (113)
- 634 Abscess, lung (114b)
- 637 Diseases of the respiratory system, e.e.e. (114a, 114b)

IX. DISEASES OF THE DIGESTIVE SYSTEM

- 640 Vincent's angina (115a)
- 643 Tonsillitis (115a)
- 646 Diseases of the pharynx, e.e.e. (115a)
- 648 Infected or impacted teeth (115b)
- 649 Parotitis, e.e.e. (115c)
- 653 Diseases of the buccal cavity and annexa and lip, e.e.e. (115b)
- 655 Stricture, esophagus (116)
- 657 Diverticulum, esophagus (116)
- 660 Diseases of the esophagus, e.e.e. (116)
- 662 Ulcer, stomach (117a)
- 664 Ulcer, duodenum (117b)
- 666 Ulcer, jejunum (123)
- 668 Peptic ulcer, not specified as to location (123)
- 670 Dyspepsia (118)
- 673 Cardiospasm (118)
- 675 Diseases of the stomach, e.e.e. (118)
- 678 Colitis, ulcerative (120)
- 681 Diarrhea and enteritis, e.e.e. (119, 120)
- 684 Appendicitis (121)
- 687 Hernia, inguinal (122a)
- 689 Hernia, abdominal (122a)
- 692 Hernia, diaphragmatic (122a)
- 694 Hernia, femoral (122a)
- 697 Hernia, vaginal (122a)
- 701 Hernia, intestinal, e.e.e. (122a)
- 703 Diseases of the anus and rectum, e.e.e. (123)
- 706 Intestinal obstruction (122b)
- 710 Diseases of the intestines, e.e.e. (123)
- 712 Cirrhosis of the liver, specified as alcoholic (124a)
- 715 Cirrhosis of the liver, not specified as alcoholic (124b)
- 717 Yellow atrophy of the liver (125a)
- 720 Diseases of the liver, e.e.e. (125b)
- 722 Biliary calculus (126)
- 725 Cholecystitis (127)
- 729 Diseases of the gallbladder and biliary passages, e.e.e. (127)
- 731 Diseases of the pancreas, e.e.e. (128)
- 734 Peritonitis, e.e.e. (129)
- 736 Subphrenic abscess (129)

X. DISEASES OF THE GENITO-URINARY SYSTEM

- 744 Nephritis, e.e.e. (130, 131, 132)
- 746 Displaced kidney (133)
- 749 Purulent infection, kidney (133)
- 751 Polycystic kidney (133)
- 755 Diseases of the kidneys and ureters, e.e.e. (133)
- 756 Renal calculus (134)
- 758 Ureteral calculus (134)
- 761 Vesical calculus (134)
- 767 Cystitis (135)
- 770 Fistula, bladder (135)

- 774 Diseases of the bladder, e.e.e. (135)
- 776 Stricture, urethra (136a)
- 780 Diseases of the urethra, e.e.e. (136b)
- 781 Diseases of the urinary system, e.e.e. (136b)
- 782 Calculus, prostate (137)
- 786 Prostatitis (137)
- 788 Diseases of the prostate, e.e.e. (137)
- 791 Orchitis (138)
- 796 Diseases of the male genital organs, e.e.e. (138)
- 805 Diseases of the ovaries and diseases of the tubes and parametrium, e.e.e. (139a, b, c, e)
- 807 Conditions of endometrium, e.e.e. (139c)
- 810 Malposition, pelvic organs, female (139c)
- 816 Multiple pelvic diseases, female (139a, b, c, e)
- 820 Diseases of the uterus, e.e.e. (139c)
- 821 Menopause (139c)
- 825 Mastitis (139d)
- 829 Nonpuerperal diseases of the breast, e.e.e. (139d)
- 831 Vaginitis (139e)
- 835 Diseases of the female genital organs, e.e.e. (139e)

XI. DISEASES AND CONDITIONS OF PREGNANCY, CHILDBIRTH AND PUERPERAL STATE

- 838 Abortion (140, 141)
- 843 Ectopic pregnancy (142a, b)
- 847 Pregnancy, e.e.e., with parturition here (143)
- 848 Pregnancy, e.e.e., with parturition elsewhere (143)
- 851 Placenta praevia (144a)
- 853 Puerperal Hemorrhages, e.e.e. (144b)
- 855 Puerperal septicemia and pyemia (145a)
- 858 Eclampsia (146)
- 860 Toxemia of pregnancy, e.e.e. (147)
- 863 Puerperal phlegmasia alba dolens, embolus, or phlebitis (148)
- 865 Conditions of the puerperal state, e.e.e. (145b, 150)

XII. DISEASES OF THE SKIN

- 868 Furuncle, carbuncle, acute inflammation skin (151, 152)
- 873 Herpes (153)
- 875 Pemphigus (153)
- 878 Scleroderma (153)
- 882 Diseases of the skin, e.e.e. (153)

XIII. DISEASES OF THE BONES AND ORGANS OF LOCOMOTION

- 885 Osteomyelitis (154)
- 887 Paget's disease, bone (155)
- 890 Fracture, acute, skull (194b)
- 894 Fracture, acute, bone, e.e.e. (194b)
- 895 Fracture, old, any bone (155)
- 905 Diseases of the bones, e.e.e. (155)
- 908 Arthritis, e.e.e. (155a)
- 910 Dislocation, joint (156a)
- 913 Sacro-iliac disease (155a)
- 916 Diseases of the joints, e.e.e. (156a)
- 918 Myasthenia gravis (156b)
- 921 Bursitis (156b)
- 923 Myositis ossificans (156b)
- 926 Talipes, acquired (156b)
- 928 Torticollis (156b)
- 931 Dupuytren's contracture (156b)
- 935 Diseases of the organs of locomotion, e.e.e. (156b)

XIV. CONGENITAL MALFORMATIONS

- 938 Hydrocephalus (157a)
- 940 Spina bifida and meningocele (157b)
- 943 Congenital malformations of the heart (157c)
- 945 Branchial cyst (157d)

- 948 Congenital talipes (157d)
- 950 Harelip (157d)
- 953 Hirschprung's disease (157d)
- 955 Hypospadias (157d)
- 956 Undescended testicle (157d)
- 957 Congenital malformations, genito-urinary system, e.e.e. (157d)
- 958 Imperforate anus (157d)
- 961 Congenital defects, e.e.e. (157d)

XV. DISEASES AND CONDITIONS OF EARLY INFANCY

- 963 Normal birth
- 965 Premature birth (159)
- 966 Stillbirth
- 967 Injury at birth, in new born (160)
- 969 Atelectasis, in new born (161a)
- 971 Icterus of the new born (161b)
- 974 Diseases peculiar to early infancy, e.e.e. (158, 161c, d)

XVI. SENILITY

- 976 Senility (162)

XVII. INJURIES

- 986 Injuries by animals (176, 188)
- 988 Injuries, acute, e.e.e. (184-214)
- 989 Injuries, old (posttraumatic and postsurgical conditions included)
- 990 Foreign body, bronchus or digestive tract, including larynx and lung (194a)
- 992 Foreign body, e.e.e. (194a)

XVIII. MISCELLANEOUS

- 994 Follow-up examination, postoperative, except neoplasm—310
- 995 Diseases, e.e.e. (69)
- 996 Hospital investigation
- 997 Negative general examination
- 998 No diagnosis or incomplete examination
- 999 Confidential file

TABLE II
General Summary
Diagnoses in 1936
Total Patients 65,097

Diagnoses	Patients			
	Total	Non-Surgical		Surgical
		Out Patient	Hos-pital	
I Infectious and Parasitic Diseases				
Typhoid fever	2		2	
Paratyphoid fever	2	2		
Undulant fever	19	13	6	
Measles	8	8		
Scarlet fever	49	28	21	
Whooping cough	17	17		
Diphtheria	3		3	
VII Diseases of the Circulatory System				
Rheumatic heart disease	251	212	36	3
Hypertensive heart disease	674	434	237	3
Subacute bacterial endocarditis	21	6	14	1
Angina pectoris	734	636	97	1
XVIII Miscellaneous				
Check-up examination, post-operative, except neoplasm	989	898	37	54
Diseases, e. e. enumerated	2,017	1,703	177	137
Hospital investigation	751		626	125
Negative general examination	1,702	1,702		
No diagnosis or incomplete examination	2,847	2,847		

In making our reports we do not attempt to select from among several simultaneous diagnoses a single "primary" one to be reported, but the same diagnosis is not assigned more than once to a particular patient in any one year, regardless of the number of visits or hospitalizations. In principle there is no limit to the number of simultaneous different diagnoses that may be enumerated; in practice, comparatively trivial diagnoses are not reported and overlapping diagnoses are combined into unit diagnoses referable to a single, definite condition. The cases in each rubric are reported in terms of the total number of patients,

and, of these, the number of outpatients, the number hospitalized surgically, and those hospitalized non-surgically. The form of a report is given in Table II.

Nursing Service Honored

AT the opening session of the National Nursing Biennial Convention, held in the Municipal Auditorium, Kansas City, Mo., April 25, the Walter Burns Saunders Memorial Medal was presented to Helen McDonough, of Pittsburgh, Pa., Chairman of the Private Duty Section of the American Nurses' Association, as representative of all bedside nurses. Dr. Loyal Davis, professor of surgery at North Western University Medical

School, Chicago, Ill., made the award.

The recipient of the medal is decided upon by a Committee of Awards, composed of the presidents of the three national nursing organizations—the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing—and of W. L. Saunders of Philadelphia, in memory of whose father the medal is presented at each Biennial Nursing Convention.

The Acute Diarrheal Disorders*

A. V. HARDY, M.D., DR.P.H., AND JAMES WATT, M.D.

*U. S. Public Health Service, the Indian Medical Service, and the
DeLamar Institute of Public Health, Columbia University,
New York, N. Y.*

OUR anxieties and activities as public health workers appear to be the product of two influences—public concern vigorously expressed, and our own convictions as to the relative importance of various problems. For the former reason epidemic diarrheal diseases demand our attention. The outbreaks are explosive in character, often widely distributed, and the ailments are distressing. A satisfactory explanation and effective preventive measures are demanded. Under these circumstances there is but slight consolation in the knowledge that the epidemic diarrheal disorders are commonly of short duration and rarely hazardous to life. We are, and we must be, concerned with these outbreaks, but we must also evaluate accurately the relative importance of the epidemic and endemic diarrheal disorders.

The study which provides much of the data of this report is being conducted in Bernalillo County, N. M., and adjacent Indian communities, an area with an estimated population of 55,000. During July and August, 1937, there occurred among infants and young children within this region 57 reported deaths from the acute diarrheal disorders. This represents the results of

an endemic disease. Though such a high incidence of these conditions is unusual in this country, it remains true that in 1934 a total of 26,584 deaths in the United States were attributed to "diarrhea and enteritis" and "dysentery." Further, it is readily established that for each fatality there occur several severe cases of non-fatal diarrheal disease in the young or aged, and an even larger number of milder disorders involving older children and younger adults.

Though varying widely in frequency, these are disorders familiar to all areas. They warrant and should now receive the same persistent interest and attention which has already been given with such gratifying effect to typhoid fever.

CLINICAL CONSIDERATIONS

For general clinical purposes the diarrheal diseases may be separated into two groups, those due to proliferative and non-proliferative agents; that is, the infectious and non-infectious disorders. If the latter result from a single ingestion of irritating substance, the condition will persist only for the few hours necessary to evacuate the intestinal tract. The severity will be dependent upon the magnitude of the dose of offending material. The familiar member of this group is staphylococcal food poisoning. Occasionally there is a repeated ingestion of small doses of

* Read before a Joint Session of the Public Health Engineering and Epidemiology Sections of the American Public Health Association at the Sixty-sixth Annual Meeting, October 7, 1937.

toxic material. Clinically these cases can be identified with difficulty, if at all. In outbreaks of this type the diagnostic problem rests chiefly with the epidemiologist. Other varieties of non-infectious diarrheas tend to be milder but more persistent. These may be dependent on dietary factors, as the daily ingestion of excessive carbohydrates by infants and excessive roughage by adults. Constitutional influences may also be concerned—allergic idiosyncrasies, psychic or neurological instabilities, or structural abnormalities. These are the concern of the practising physician whose duty it is to study the peculiar needs of single individuals. No further attention will be given at this time to these clinical entities.

For purposes of this discussion, the infectious diarrheas are defined as those due to the presence and multiplication of microorganisms within the lumen or wall of the intestinal tract. Whether these produce damage by the elaboration of toxic products or by parasitic growth in or on the walls of the tract is of secondary importance. Clinically these disorders tend to begin rather suddenly. The healthy individual as a rule first notes mild abdominal distress followed in a few hours by frequent evacuations and increasing pain. The temperature may or may not become elevated. The stools may or may not become bloodstained. Pus cells may usually be observed but are not always present. In severity and course these disorders are most variable. They may be merely transient and mild annoyances, they may run a stormy and protracted course, or they may be fulminating fatal illnesses.

The differential clinical diagnosis of the diarrheal disorders presents unusual difficulties. There is but one outstanding symptom—diarrhea—and this may arise from a wide variety of causes. The associated complaints, such as

nausea, vomiting, and abdominal pain, are few and have practically no differential value. Physical examination usually reveals little other than the signs of dehydration and some abdominal tenderness. Of some diagnostic significance are the temperature and character of the evacuations, but even these provide uncertain evidence as to etiology. In studying series of cases, the clinical course of the disease and the epidemiological observations provide indications valuable for diagnosis. Utilizing all of these data, we have concluded that the greater proportion, well over 90 per cent, of diarrheal disorders observed in our studies were acute enteric infections. Further than this it was impossible to go without the evidence presented by laboratory studies.

In considering the usual clinical classification and descriptions of the diarrheal diseases, it must be remembered that heretofore with few exceptions only cases severe enough to be hospitalized have been examined etiologically. Thus it has come about that bacillary dysentery has been observed as a serious disease characterized by sudden onset, with fever, abdominal pains, and the frequent passage of bloody muco-purulent stools. Field studies involving the etiological examination of diarrheas of all degrees of severity rapidly reveal an amazing variability in the clinical manifestations of bacillary dysentery, as is also true in amebiasis. The common error of the past has been to consider specific infections only in severer diarrheal disorders. We must carefully avoid this mistake in future.

ETIOLOGICAL STUDIES

That diagnostic laboratory studies of the diarrheal diseases have a proper and important place in the public health program has been both demonstrated and stated by several workers. For various reasons this remains a procedure

called for but infrequently and advocated but rarely. As illustrative of the productiveness of these examinations, let us state our own experience in the study in New Mexico. The positive findings reported include only the already identified strains. It is expected that the further study of additional and less typical organisms will increase somewhat the proportion of positives.

In the first 1,000 stool specimens examined culturally following July 1, 1937, 398 were submitted for the diagnosis of diarrheal disorders. The remainder were studied for epidemiological reasons. Of the diagnostic specimens, 147 (36.9 per cent) yielded organisms of the genus *Shigella*. Excluding cases in which but one stool was submitted and found to be negative, we examined for diagnostic purposes during July and August a total of 192 persons. From 128 (62.5 per cent) of these, *S. dysenteriae* were isolated. Further, of 22 fatal cases studied during the same period, 17 (77.3 per cent) yielded *S. dysenteriae*. Only 3 of the 5 negative fatal cases had as many as the minimum of 3 specimens considered essential for reasonably reliable diagnosis. Any test for a communicable disease which yields this proportion of positives, or even much less, is amply justified.

That stool cultures for diarrheal disorders are productive is clearly apparent, but even more evident are the difficulties involved in a satisfactory application of this procedure. Here we have to deal not with one organism of relatively constant characteristics, as in typhoid fever, but at least two families of organisms, the *Shigella* and *Salmonella*, each with several members varying in type, and with many strains readily tending to reveal varying characteristics in different environments.

We have already found that there is unusual importance in the selection of laboratory procedures. During 1936,

we employed our then favorite medium, eosin-methylene-blue agar. Due to a limited supply of glassware we were restricted to 2 plates per specimen. This year we added 3 other differential media, using now a total of 4 plates per specimen. The proportion of positives found among diagnostic specimens has been more than doubled with a resulting increase of more than 50 per cent in the proportion of positive cases. A small part of this change may possibly be attributed to the influence of experience. A little more may be due to the fact that in 1936 few other cases than those in infants were examined, whereas in 1937 a number of illnesses in adults were reported and usually found positive for *S. dysenteriae*. That these influences are of negligible importance seems apparent since in 114 (57 per cent) of the first 200 positive specimens this year the organisms were found only on 2 of the types of media newly employed. By far the best results have been obtained on desoxycholate citrate agar. This yielded the organisms in 166 (83 per cent) of the 200 positives. The proportions of the other 3 media which yielded positives were plain desoxycholate agar, 33.7 per cent, Endo's agar 30.2 per cent, and eosin-methylene-blue agar 26.5 per cent. The relative value of these media for the isolation of the Sonne variety of *S. dysenteriae* is not yet reliably indicated in our study, but even for this the desoxycholate citrate agar apparently yields quite as good results as the other media employed. The importance of selecting the best laboratory procedures available is evident. Is it not also likely that further advances in the study of the diarrheal diseases may be made if technics are examined critically and revised or devised specifically for these disorders?

That the Flexner and Sonne varieties of *S. dysenteriae* are the major cause of the acute diarrhea in this country

has been as certainly demonstrated in other areas as in New Mexico—for example, in Henrico County, Va., by McGinnis,¹ and in Los Angeles by Kessel.² It seems equally clear that other organisms do give rise to infectious diarrhea.* Occasionally we have been able to incriminate one of the *Salmonella* group and very rarely *Eberthella typhi*. It seems probable that still other organisms are involved but definite incriminating evidence is difficult to obtain and continues to be lacking.

That the etiology of the diarrheal diseases may vary as markedly in different areas, as does the incidence, seems possible. However, our own experience forces us to conclude that the most effective approach to these disorders is to use the best bacteriological methods available for the identification of specific etiological agents.

EPIDEMIOLOGICAL OBSERVATIONS

As illustrative of the methods employed and certain of the interesting observations in the epidemiological study of the acute diarrheal diseases, I am reporting a portion of a not yet completed study in a small village in New Mexico. Findings are somewhat unusual in the richness of the positive observations but conform in type to those in 3 other areas similarly studied.

Chilili is a relatively isolated Spanish speaking community with a summer population of 210 persons. The public health nurse visits the area once weekly. On August 20 she reported that she had found a baby aged 24 days very sick with acute diarrhea, and that 2 other infants were having milder symptoms, which had then persisted for almost a week. The inquiry had also revealed the recent occurrence of

mild diarrhea involving adults in 2 different families. Platings from a diaper brought to the laboratory revealed that the young infant had a *S. dysenteriae* infection. Hospitalization was refused, the course was rapidly downward, and the child died 3 days after first seen.

Inquiry in the 5 families from which cases of acute diarrhea had been reported revealed no common exposures or close relationships. However, a clear record of a communicable disease was given in the family with the fatal case of proven bacillary dysentery. A visiting grandmother had come from the home of a son where 2 adults had recently been troubled with diarrhea. She herself had a mild diarrhea on arrival. Within 10 days 4 of 5 adults and 2 (1 the fatal case) of 3 children had acquired the same disorder. The mother of the young infant was ill for 4 days and in bed for 2; the other adults and a child of 4 years made no complaint beyond the second day.

The people of this area had attained the reputation of being particularly coöperative with the Health Department. A detailed study seemed both promising and warranted. In undertaking this, the object was to collect complete records concerning the occurrence of diarrheal disorders, to obtain stool specimens from all or almost all of the people, and to make a house-to-house sanitary survey of the area. The stool specimens were willingly provided by a large majority of the people. Four families with histories of diarrhea (in 2 instances with proven cases of bacillary dysentery) found it too inconvenient to comply with our request, as did 6 others in which the people had been continuously well. In all, laboratory specimens were obtained from 155 individuals. Three of these were active clinical cases—all proved to be positive for *S. dysenteriae*. Of those who were well at the time of the

* Subsequent serological study of our isolated organisms revealed a substantial number of strains antigenically identical with Clayton and Warren's "Newcastle dysentery bacillus."

examination, 18 (11.6 per cent) yielded the same organism. Including the 3 cases, 20 of the 21 positives were within a delimited area which included about one-half of the residents of the village. These findings are to be compared with the more normal population groups, in which the carriers of *S. dysenteriae* are quite rare. Studies here are unfortunately too meager or uncertain to permit the statement of any numerical proportions.

It is apparent that in this village *S. dysenteriae* had infected a great many—substantially more than these positives which were found as a result of one test only. A further striking feature is that there existed the widest variation in the reaction by different individuals to the parasitic organisms. Adults were either undisturbed or had a mild diarrhea while some children were overcome with a severe, and in 2 instances fatal infection. Observation of severe cases alone would have produced no useful epidemiological evidence; observation of all cases, including the mild transient disorders, would have given a very incomplete picture; but a study of the whole population group did give an epidemiological picture which clearly indicated significant variations in incidence.

In formulating the epidemiological approach to the diarrheal disorders, the varying and usually mild pathogenicity of many of the etiological agents must be appreciated. We have to deal with a group of organisms near the borderline which separates the parasitic and saprophytic agents. Often they may and do assume the rôle of the latter, or at most they may be but mildly pathogenic. Occasionally in susceptible individuals their parasitic properties become fully evident. It is not the latter which we must seek to examine, but rather the spread and history of the organisms in all their relationships.

PREVENTION

A very simple experimental examination of preventive measures is now under way as a part of our studies in New Mexico. For this test a semi-rural area with a population of approximately 1,000 was selected, in which the incidence of acute diarrhea has been consistently high in recent summers. A representative sample of the inhabitants was also examined in 1936 and a relatively high incidence of carriers of *S. dysenteriae* was found. During the winter at public expense the universally insanitary privies were replaced by sanitary ones. Save for the incidental education concerning the maintenance and use of these, no other changes were made. It is safe only to comment that during the summer of 1937 the total incidence of diarrheal diseases was very low and that the carriers of *S. dysenteriae* had declined in number, though still numerous enough to permit ready spread of the specific infection in a favorable environment. Despite the optimism of families concerned and the physicians serving the area, judgment must be reserved. It is noteworthy, however, that no such decline has taken place in areas in which only a portion of the population had been provided with effective sanitary arrangements. Complete sanitation appears to provide effective protection while partial sanitation evidently has little value.

The incidence of typhoid fever has heretofore served as an index of the adequacy of sanitation. It is suggested that in the diarrheal disorders we have a more sensitive measure and the one which may well be commonly employed in the future.

SUMMARY

The prevention of mortality and morbidity from the acute diarrheal diseases remains an important public health problem.

Clinically these disorders may be classified with reasonable accuracy as non-infectious and infectious. The former are usually acute and of very short duration, or mild and quite chronic. The latter vary widely in manifestation. Clinical characteristics do not serve to separate reliably the *Shigella* infections from other infectious conditions.

Cultural studies are essential for reliable diagnosis. Success in this varies widely, depending in large measure on the differential media employed. Attention is called to the value of the desoxycholate citrate agar.

In epidemiological studies designed to determine the incidence or spread of these infections, it is essential that healthy individuals and those mildly ill be examined with the same interest and care as those severely ill.

The major problem in the prevention of the acute diarrheal disorders appears to be the more effective prevention of the dissemination of human excrement.

Carbolized Vaccine for Animal Bites

FOR bitten people treated by one or the other of two methods (carbolized vaccine or Pasteur's method) in 1933, with 100 as the standard, in 1934 there were 93.30 and for 1935 there were 81.10. For patients treated who were bitten by animals known to be rabid in 1933, with 100 as standard, there were 79.80 in 1934 and only 57.20 in 1935.

For the whole period of 3 years, among 5,918 patients treated, of whom 787 (13.20 per 100) were bitten by animals known to be rabid, there

were only 5 failures, 0.08 per 100.

The study of several types of anti-rabic vaccine have led to the conclusion that the carbolized vaccine has an indisputable superiority on account of the ease of preparation and of use, and also on account of the ease of transportation and its keeping qualities. It is the most economical and rarely causes local reactions in the persons treated.—Prof. Petragnani, *Protection Contra La Rage en Italie, Office International D'Hygiene Publique*, Mar., 1938, p. 168.

A Water-Borne Outbreak of Gastroenteritis in a Tennessee Town*

CRIT PHARRIS, M.D., F. W. KITTRELL, AND
W. C. WILLIAMS, M.D., F.A.P.H.A.

State Department of Public Health, Nashville, Tenn.

LATE in the summer of 1936, it came to the attention of the State Health Department that an East Tennessee town of approximately 2,500 inhabitants was experiencing a moderately extensive epidemic of gastro-intestinal disorder and that similar outbreaks of variable severity had been experienced at irregular intervals for several years. The annoyance of repeated outbreaks had finally created sufficient public interest and concern to cause a request for an investigation. The extent and severity of previous outbreaks are unknown since epidemiological and morbidity data for previous years were not reliable.

Unfortunately, neither of the rather well defined outbreaks occurring in June and August, 1936, was reported until after each had practically subsided. The epidemiological approach was not unlike the usual procedure in an investigation of this type. The data included in this report were procured as a result of a house-to-house survey which was made of the entire town immediately after the last outbreak in August. Epidemiological, engineering, and laboratory personnel coöperated in this coördinated study.

The town has municipally owned and operated water and sewerage systems, which serve approximately 95 and 82 per cent, respectively, of the population. General economic, social, and public health conditions were considered fairly typical for a town of this size.

SURVEY FINDINGS

A. Epidemiological

A total of 765 persons, or approximately 31 per cent of the town's population, was found to have had one or more rather well defined attacks of gastroenteritis from May 16 to September 2, 1936. A small number of cases was excluded from the final summary because of the vagueness of symptoms or lack of information suitable for statistical analysis. The morbidity rate for a nearby town was found by actual survey to be 24 cases per 1,000 population as compared to a rate of 312 in the epidemic area. Only 17 clinical cases were found during the house-to-house survey. Efforts to isolate the probable causative organism from these cases were not successful.

More than 90 per cent of the cases gave a history of sudden onset with nausea, vomiting, and epigastric discomfort of variable degree and duration, usually lasting from 2 to 10 hours. The majority of cases gave a

CHART I

CASES OF GASTRO ENTERITIS IN A TENNESSEE TOWN, MAY 16 - SEPTEMBER 2, 1936

history of diarrhea, abdominal pain, distension and mild tenesmus within 4 to 10 hours after onset. These symptoms persisted from 2 to 6 days, depending largely upon the time treatment was begun. Some of the untreated cases reported the passage of small amounts of blood and mucus. Approximately 50 per cent gave a history of a slight elevation of temperature. Weakness was found to be directly proportionate to the severity of the symptoms. There were no reliable data indicating the formation of any degree of immunity against the offending agent, although there were some indications that the first attack was usually more severe than subsequent ones.

The case distribution was uniform throughout the urban and suburban areas receiving city water. Chart I shows the time distribution as determined by the survey. It is of more than passing interest that the peaks of the 3 major outbreaks occurred on Saturdays. We

can only surmise the probable explanation of this phenomenon. Although the survey was discontinued early in September it was later learned that of the 179 students in a local private school served by this municipal system, 62 typical cases occurred during the weeks and week-ends of September 5, 12, 19, and October 17. It was later learned that similar fall and spring outbreaks had occurred in this institution during preceding years with annoying consistency.

All cases were uniformly distributed by age, sex, color and occupation. Careful inquiry failed to incriminate a possible source of infection such as foods, milk, ice, community gatherings, visits out of town, sanitation, etc. The only vehicle common to the majority of cases was city water—actually 89.2 per cent of the cases were found to have used the city water supply almost exclusively, with an additional 8 per cent having used city water most of the time. The uniform distribution of

cases throughout the city, the explosiveness of the major outbreaks, the relative mildness of the attacks, and the uniform distribution by age, sex, and color, together with the known condition of the water supply were sufficient to justify a comprehensive study of the entire water supply system.

B. Engineering

A large spring with a dry weather flow of about 450 gal. per minute and coming from a limestone region containing numerous caverns and sink-holes provided an adequate raw water supply for the town. The concrete storage basin of 50,000 gal. capacity at the spring was inadequately protected against surface contamination. An elevated tank and standpipe holding 75,000 and 325,000 gal., respectively, floated on the system to provide storage and equalize pressure. Chlorine was applied to the pump suction and the water pumped immediately to the distribution system without further treatment.

The State Health Department engineers have since 1931 recognized certain potential dangers of contamination from 4 known cross-connections. Repeated but unsuccessful recommendations have been made for their elimination. The operation records of the system submitted to the State Health Department have been excellent. These records together with routine engineering investigations indicated that the supply was reasonably safe. Daily tests indicated a chlorine residual of 0.2 to 0.4 p.p.m. throughout the preceding 2 years. Daily turbidity tests covering 6 weeks early in 1936 showed excessive turbidity following rains. These readings varied from 5 or less to as high as 340 following a heavy rain on the watershed, but apparently bore no significant relationship to the epidemics. Further studies revealed an actual chlorine residual of only 0.1 p.p.m. in-

stead of the 0.2-0.4 p.p.m. previously reported. The operator's error in reporting chlorine residuals was due to defective color standards and a previously unsuspected chlorine demand of the untreated water. The water level in the tanks was found to be gradually decreased during the week and built up over week-ends, causing the pump pressure to vary from 75 lb. on Mondays to 70 lb. on Fridays. The pump discharged at a rate of 260 gal. per min. at 75 lb. and 310 gal. per min. at 70 lb. pressure. The chlorinator setting was never changed to compensate for this fluctuation, and a chlorine residual of 0.1 p.p.m. on Mondays would have been even less on Fridays, perhaps below the safety margin for adequate disinfection. The chlorine dosage was increased on September 15 to maintain a residual of 0.25 p.p.m. Despite this, epidemic cases continued to occur as late as October 25. More complete investigations indicated that cross-connections probably were not contributing to the local problem.

C. Laboratory

Monthly bacteriological examinations had at no time in the past 2 years given any indication of contamination. At the time the study was begun, 6 stations, 5 on the distribution system and 1 at the untreated source, were selected for the collection of daily samples. Samples for bacteriological and chlorine residual determinations were taken from September 14 through December 14. During this period only 2 samples of the treated water, one on September 24 and one on November 13, showed contamination, and of these only 1 of the 5 10 c.c. portions showed the presence of organisms of the coli-aerogenes group. Two samples, both collected on September 14, showed a chlorine residual of 0.0. The average for all stations during the period was about 0.2 p.p.m. None of the treated samples

taken for bacteriological analysis was dechlorinated before shipment and approximately 18 hours elapsed between collection and arrival at the state laboratory. The untreated samples showed a widely fluctuating coli-aerogenes contamination, varying from an occasional zero to more than 24,000 organisms per 100 c.c. on numerous occasions. The highest recorded finding was 240,000. There was no evidence to indicate that the outbreaks were of chemical origin.

D. Miscellaneous

A terra-cotta sewer outfall serving about 75 homes, with an estimated average discharge of 6 gal. per min., passed within 60 ft. of the spring (Chart II). On November 10, it was noted that there was no discharge of sewage at the sewer outlet. A check of manholes revealed a steady flow at No. 5 but only an intermittent flow at No. 4. Excavation of the sewer outfall between these two points was started immediately, and on November 14 a leak was found about 40 ft. higher than the spring and 200 ft. away. Sewage was flowing through an improperly sealed joint and into a cavern which appeared to lead toward the spring. This leak was stopped immediately. The terra-cotta outfall was later replaced with cast-iron pipe. A storm drain was also found to be emptying into the sewer and apparently was the principal cause of the turbidity previously referred to.

The improvement in bacterial quality of the untreated spring water following this correction is shown in Table I. The reduction in turbidity has been equally noticeable since the sewer was repaired, with only 6 readings exceeding 10 and none exceeding 25.

A connection between the point at which the sewer leaked and the spring was proved by the use of a salt solution. One hundred lb. of salt were dis-

ACCOMPLISHMENTS

A large portion of the terra-cotta sewer outfall has been replaced with cast-iron. The quality of the raw water showed a marked improvement after the sewer defect was corrected. The most dangerous cross-connections, although not implicated in the outbreaks, have been eliminated. Subsequent investigations have revealed that outbreaks of gastrointestinal disorders among those using city water have been conspicuously absent since the sewer line was repaired. It is particularly noteworthy that for the first time in several years spring and fall outbreaks of the disorder have not been experienced in the private school mentioned.

SUMMARY AND CONCLUSIONS

The etiology of the outbreaks is unknown but available evidence indicates that it was most likely transmitted

through the public water supply. Knowledge of possible conditions contributing to the contamination of this particular supply would lead one to suspect that one or more factors may have contributed to the outbreaks. Among them are:

1. Bacteria of the colon-typhoid-dysentery groups in the supply as a result of excessive raw water contamination and an inadequate purification process.
2. Bacteria not found by ordinary methods of water analysis. Samples were not dechlorinated at the time of collection, hence may have become sterilized during the period of transportation.
3. Bacteria not suspected, due perhaps to destruction of indicator organisms before reaching the laboratory.
4. Toxic products created as a result of septic action in the sewage that reached the raw water supply. Based on the probable concentration of such products in the supply, this possibility is considered rather remote. However, the fact that all cases recovered rapidly and without sequelae together with the absence of typhoid and paratyphoid cases in the population group over a period of years gives some support to this theory.

The study suggests: (1) The need of more exhaustive studies in this particular field, particularly as to determination of the causative organism. (2) That the epidemiologist, engineer, bacteriologist and public health administrator have specific responsibilities in coördinated studies. (3) That field laboratory equipment should be made available for studies of this type in event satisfactory laboratory facilities are not readily accessible. (4) That the more common factors contributing to these outbreaks should be eliminated before we seek the indefinite if not hypothetical cause.

Gastrointestinal Disorder Not Proved To Be Water-Borne*

D. G. GILL, M.B., D.P.H., F.A.P.H.A., AND
JAMES G. McALPINE, PH.D.

*Director, Bureau of Preventable Diseases; and Director, Bureau of
Laboratories, State Department of Health, Montgomery, Ala.*

REPORTS of epidemics of intestinal disturbances are quite common. In many instances the causative organism is readily found and the vehicle of transmission is apparent. Other more puzzling outbreaks occur in which presumptive evidence alone is obtained.

It is desired to report an epidemic of the latter type, which is of interest largely on account of the extensive studies that were made and the procedures followed.

Situated on the Chattahoochie River, which separates Alabama and Georgia, are the twin towns of West Point, Ga., and Lanett, Ala., and extending in almost continuous form from Lanett, Ala., are the various mill villages of the West Point Manufacturing Company—namely, Shawmut, Fairfax, Langdale, and Riverview. Reports as to the occurrence of cases of persistent diarrhea in this population of some 25,000 people were made during the latter part of 1935 to both the Georgia and Alabama Health Departments. The first supposition was that the disease was amebic dysentery and many of the cases were reported as such. Early

in 1936 the Health Officer of Chambers County, Ala., reported the disease to be on the increase and this led to an investigation.

LABORATORY PROCEDURES

As a preliminary step it was decided that fresh specimens should be examined from a number of these patients to confirm the tentative diagnosis of amebic dysentery. Owing to the distance from any established laboratory in the state system, a field laboratory was set up and a clinic held on February 12 and 13, 1936. Sufficient equipment was taken to make warm stool examinations and cultural studies for bacillary dysentery, and any pathogenic fungi which might be present. Differential blood counts were run and occult blood determinations were made on all specimens. Careful case histories were obtained from all patients.

Warm stools were examined microscopically for intestinal parasites. Fresh feces were plated on Endo's medium for bacillary dysentery and portions were inoculated into lithium chloride glycerine and streaked on 5 successive days on Endo plates for organisms of the typhoid-paratyphoid group. Liver infusion agar with rice starch and serum was employed for the determination of amebic cysts. Plates

* Read at a Joint Session of the Public Health Engineering and Epidemiology Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

of Sabouraud's maltose agar were streaked for the presence of pathogenic fungi.

During the 2 days, 25 patients and 14 milk handlers were examined. It was soon apparent that *Endameba histolytica* was not present. Cultural results for bacillary dysentery, organisms of the typhoid-paratyphoid group, and fungi were negative. The only finding of note was the presence of an unidentified flagellate in 5 of the 25 patients and in 1 of the 14 dairymen. The differential counts were normal but occult blood was present in a large number of fecal specimens.

Since the flagellate was the only lead it was decided to repeat the clinic and concentrate all efforts on the isolation and identification of this organism. Accordingly, on February 25 and 26, 28 patients, some of whom were the same as in the first clinic, were examined. Direct smears were studied and cultures made on Loeffler's serum saline. Also, smears were stained from iron hematoxylin.

The cultures were brought back to Montgomery where they received intensive study. The organism was definitely identified as *Trichomonas hominis*. Forty-two patients were examined during the 2 visits to Lanett. Of these, 11 showed the presence of *Trichomonas hominis*. Thirteen patients were examined at both sessions, 1 showed the presence of this organism both times, and 1 negative the first time was positive during the second examination. Although our sample of 2 cases is quite small, this does show that there is some intermittency in the discharge of this organism.

On March 6, the Georgia State Department of Health conducted a clinic in West Point. The stools of 13 patients were examined and blood counts made on each. Eosin-methylene-blue plates were streaked on successive days for the presence of members

of the typhoid-paratyphoid-dysentery group; blood agar slants were inoculated for streptococci; Sabouraud's medium was used for the detection of pathogenic fungi, and differential counts were performed. Their findings were as equally indefinite as ours in the first 2 clinics.

Because the pathogenicity of *Trichomonas hominis* is disputed, and this was the only organism found which might be a causative factor, it was decided in a conference with representatives from both the Alabama and Georgia State Departments of Health that consultant assistance was essential. Accordingly, Dr. Justin Andrews, of the Johns Hopkins University, and Dr. A. V. Hardy, of the U. S. Public Health Service, were invited to assist in the next investigation. A clinic was arranged in Lanett March 24 to 26, at which time 95 patients from Alabama and 32 from Georgia were examined. Thirty-five of these were reexamined to confirm their original findings. Fourteen normal individuals were submitted as controls.

The same general methods were employed, with the Alabama technicians doing the direct examinations, and the Georgia technicians being responsible for the bacteriological procedures. Dr. Andrews personally checked all specimens for protozoal content.

The specimens were collected in cardboard ice cream boxes without any preservative, some at the improvised laboratory and others by the nurses in the homes. Because of the promptness with which the cultures were made it was not considered necessary to use a preservative. Most of the specimens were still warm when cultured. All specimens were first subjected to examinations for protozoa and then cultured, the cultures being made on Endo and eosin-methylene-blue plates. At least one plate of each medium was used. Colonies were picked after 24

and 48 hours' incubation. The specimens were not replated, because primary interest was in demonstrating members of the *B. dysentery* group and it was decided that it would not be worth while to keep the specimens after the original plating.

Of the 127 patients examined, only 5 showed the presence of *Trichomonas hominis* and of the 32 who were re-examined, only in 3 was this organism demonstrated. In the normal control group *Trichomonas hominis* was not present. The intensive bacteriological study did not reveal any members of the typhoid-paratyphoid-dysentery group.

The findings from all 4 clinics were inconclusive. Amebic and bacillary dysentery were ruled out. No members of the typhoid or paratyphoid groups and no fungi were demonstrated. *Trichomonas hominis* was found at one of the early clinics, but final results did not incriminate this organism.

EPIDEMIOLOGICAL STUDIES

The symptomatology was that of diarrhea of acute onset, varying from 5 to 25 stools per day unaccompanied by any pain or tenesmus. There was no dehydration or emaciation, although weakness was usual. The feces showed no visible blood, but evident mucus. The severity of the disease varied, but once acquired it persisted over months.

The cases occurred on both sides of the river and in all the mill villages, although the largest number were present in Lanett which merges with West Point, Ga. Several hundred cases probably occurred, but 95 cases were carefully studied on the Alabama side, with an additional 32 from West Point, Ga. The date of onset varied from January, 1935, to the time of investigation in February and March, 1936; but the majority had their beginning after December 1, 1935. Some of the cases seen were, therefore, of

more than a year's duration, while others were of only a few days.

The disease was confined to the white population, but otherwise showed no predilection for any age, sex, or occupation. No evidence could be elicited that contact, travel, banquets, shellfish, common food supplies, patent medicines, fruits or vegetables, played a part. The milk supply for the area came from a number of dairies. The percentage distribution of cases was approximately in proportion to the size of the dairy and no evidence could be found to incriminate milk.

WATER SUPPLIES

The widespread distribution of cases naturally suggested water as the common source.

Lanett and Shawmut are supplied by the same distributing system, taking raw water from the Chattahoochie River and processing it by chemical coagulation, settling, filtration, and chlorination. Fairfax and Riverview have a separate system, but use the same methods. In addition, there is an industrial water supply to the bleachery at Lanett which is not chlorinated, but which has no connection with the regular system.

West Point obtains its supply from a creek on the west side of the Chattahoochie River and north of the city. The water is treated similarly to the Lanett supply and then collected in a brick reservoir which is flooded when the river stage reaches 23 feet, but this was not reached at any time during 1935 or 1936. There are connections between the West Point and Lanett systems so that water can be exchanged if necessary. In practice the exchange has been from Lanett to West Point and on several occasions during the time of the epidemic Lanett water was used in West Point.

Bacteriologic examination of all water supplies was carried out regularly and

at no time was there any evidence of an unsatisfactory finished product.

Follow-up of the Alabama cases revealed that the condition gradually improved and that no new cases occurred during the winter of 1936-1937.

SUMMARY

An epidemic of gastrointestinal dis-

order occurring in several adjoining towns is reported.

The procedures followed in attempting to establish the etiological agent are described.

The failure to incriminate any organism made epidemiological studies difficult, and no source could be found.

DISCUSSION

C. D. BOWDOIN, M.D.

Chief, Division of Epidemiology, State Department of Public Health, Atlanta, Ga.

I APPRECIATE very much the opportunity of discussing this paper, particularly, since we on the Georgia side had the privilege of collaborating with the Alabama group in this study.

Dr. Gill has forcibly brought out the following facts:

1. The absence of any bacterial agents that could account for the outbreak.
2. The absence of any protozoal organism that could be responsible for the outbreak. At this point I should like to state that an *E. histolytica* carrier was found among the controls.
3. Only white people were affected.
4. Age, sex, and occupation apparently were not factors.
5. The cases obtained their milk from a number of dairies and the percentage distribution was approximately in proportion to the size of the dairy.
6. There was no evidence that contact, travel, banquets, shellfish, common food supplies, patent medicine, fruits or vegetables played any part.

I feel that the above facts, by a process of elimination, point to the water supply. It is a matter of common knowledge that at the time there existed a "bottle neck," so to speak, in the river less than a mile below West Point. It is also a matter of record that when the river stage at West Point reached 20 ft., the stage below the "bottle neck" was only 12 ft. As pointed out, the West Point water supply was obtained from a creek just

before it emptied into the river. However, the river had to rise less than 2 ft. above the normal stage of 3.5 ft. before river water was being used for the West Point supply. The West Point intake was $\frac{1}{4}$ mile above the business district. In the business district of West Point 3 trunk sewer lines emptied into the river. The water intake of Lanett was situated at several hundred yards below West Point.

In connection with the West Point Manufacturing Company, situated at Lanett, there was a dye and bleachery works, the effluent from which was discharged at intervals into the trunk sewer line of Lanett at a point not distant from its outlet. The Lanett sewer outlet was situated several hundred yards below the Lanett water intake.

The idea which I am suggesting is that this condition may have come about as the result of a chemical discharged intermittently into the river and at times taken into the water supply of both Lanett and West Point due to the pooling action which the river must have had as a result of its narrowing at a point below the sewer outlet of Lanett. The points in support of this hypothesis are:

1. No known etiological agent could be incriminated.

2. The lack of secondary familial cases.
3. The chronicity of the disease and the absence of fever.
4. The outbreak resembled a water-borne one, except that it was not explosive.
5. The respective numbers of cases in the two towns were in proportion to the respective distances of their water intakes from the Lanett sewer outlet.
6. No cases were found among negroes, who for the most part obtained their water from wells.
7. All ages and both sexes were apparently equally affected.
8. Since the elimination of the "bottle neck" in the river no new cases have developed.

College Survey of Health

THE preliminary report of a survey of health of college students was presented to the American Youth Commission of the American Council on Education at its meeting May 10, at the Chamber of Commerce of the United States. The survey, conducted by Harold Diehl, M.D., dean of medical sciences, University of Minnesota, and Charles E. Shepard, M.D., director, Men Students' Health Service, Stanford University, covered 551 colleges and universities throughout the country.

Two general classes of health problems affect college students, the report states: those from deficient care and education in earlier years, and those associated with the college environment itself. To discover earlier deficiencies, each student, upon entering, should be given a thorough medical examination, to be followed by periodic examinations during succeeding years.

The value of a complete health examination at the time of entering col-

lege is shown by the fact that in 56 institutions where tests for tuberculosis are given as a matter of routine to all new students, approximately one-third (34.5 per cent) were shown to be infected, though only to a slight degree, with the disease.

The complete college health program, the study points out, should consist of 4 basic factors: a student health service for individuals, a campus public health service for the student body, classroom instruction in health matters, and physical education as a health activity and for correction of deficiencies. The success of any college health program depends upon the integrated development of these four principles, even though the extent may vary according to size, purpose, and resources of the individual college, it points out. In general, financing should be by means of term or annual assessments paid by the students, supplemented when necessary by funds of the institution.

Pathological and Immunological Studies in Poliomyelitis

And Their Significance in Therapy and Treatment*

MAURICE BRODIE, M.D., F.A.P.H.A.

Pathology Laboratory, Providence Hospital, Detroit, Mich.

A CONSIDERABLE amount of work has been carried on in the past few years in poliomyelitis toward the elucidation of the portal of entry and route of transmission of the virus and upon the significance of the so-called antibody or neutralizing substance. These studies have not only increased our understanding of the disease, but open to doubt previous concepts of treatment and prevention and open up new avenues for studying these.

In order to clarify and evaluate the experimental data herewith described, a few remarks about experimental poliomyelitis are needed to indicate the methods used. The disease agent, a filterable virus, cannot grow upon non-living media as do bacteria. It has a narrow range of host susceptibility, the central nervous system of man and certain monkeys, where it multiplies and produces lesions. The experimental animal of choice is the *Macacus rhesus* monkey. The spread or multiplication of the virus can be demonstrated by inoculation into the monkey, whereupon the animal develops fever, cerebrospinal

fluid pleocytosis, and flaccid paralysis. The histo-pathological picture of the cord and brain stem shows neuronoplasmia, with perivascular and interstitial infiltration. The spinal cord of such an animal can, upon suitable inoculation, produce the disease in another animal.

The neutralizing substances or so-called antibody is present in the blood serum of certain normal individuals, especially adults, and also in the serum of some convalescent humans and monkeys. A serum which contains neutralizing substance renders virus non-infective, so that the incubated mixture fails to infect monkeys.

The virus used in this and many other laboratories has been passed through monkeys for many years and is highly virulent for these animals. From time to time new strains obtained from spinal cords or nasal secretions are transferred to monkeys. It is essential to know whether such strains are related to or differ immunologically from the standard virus. This is done by testing with the new strains sera known to have neutralizing bodies for the passage virus and animals that have recovered from it. Likewise, animals recovered from the new virus and their sera are tested against the passage strain.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

THE PATHOGENESIS OF THE DISEASE IN THE MACACUS RHESUS MONKEY

The essential lesions of experimental poliomyelitis occur in the cord and brain stem and closely resemble the human findings. There has been considerable controversy regarding the route of transmission and the pathogenesis has only been established in the past few years.

Despite the systemic symptoms which may occur prior to central nervous system symptoms, one can readily rule out a primary hematogenous or lymphogenous spread. The virus has rarely been isolated from the blood or tissues other than the central nervous system.¹ In our laboratory we tested the blood of intranasally infected monkeys in the incubation period in the pre-paralytic, and late stages of the disease, and were unable to demonstrate virus.² Likewise, animals sacrificed in the pre-paralytic stage failed to show the presence of virus in the liver, spleen, lymph glands, kidneys, salivary glands or muscles.² Likewise, in keeping with the findings of others, we failed to show significant lesions outside the central nervous system in more than 50 monkeys killed in the acute stage of the disease.

The transmission of the virus through the central nervous system is not by way of the spinal fluid for it is rarely found there. We were unable to demonstrate the presence of the virus in spinal fluid removed in the incubation period, in the pre-paralytic or paralytic stages of intranasally infected monkeys.² The work of several investigators has indicated that the cellular exudate in the cerebrospinal fluid is the result of an overflow from the nervous tissue by way of the perivascular spaces. In keeping with this is the fact that symptoms may occur in the animal prior to pleocytosis or may even be absent, throughout the course of the disease.³

The idea of transmission by nerve

tracts, first suggested by Liener and Wiesner and Römer, has received considerable support by Hurst and co-workers in England and Faber and ourselves in this country. Fairbrother and Hurst⁴ traced the virus from such sites of inoculation as the brain and sciatic nerve by following the sequence of the histo-pathological changes and distribution of the virus at various stages of the disease, and concluded that it travelled by way of the nerve tracts. After intranasal instillation of virus, lesions and virus are first found in the olfactory bulbs,⁵ and follow in a general way the olfactory apparatus.^{4, 6} We^{7a} as well as Schultze and Gebhardt^{7b} have been able to prevent infection via the nasal route by sectioning the olfactory nerves. Likewise, we were unable to infect a monkey by inoculating below the line of cleavage of a sciatic nerve whose perineural sheath had been sutured. In keeping with these findings Jungleblut and Spring⁸ reported that after intracerebral inoculation into an animal with severed spinal cord, the virus failed to reach the lower segment. We have found that in animals with cut spinal cords and in which a free flow of cerebrospinal fluid was demonstrated, the virus failed to pass the gap when inoculated into either the upper or lower segment. Similar findings were obtained with both passage virus and two recently isolated strains. These experiments also help to rule out either hematogenous or lymphogenous spread of the virus for the blood supply was intact to both upper and lower segments of the cerebrospinal axis.

If the virus travels along nerve tracts one would expect its primary effects upon the neurones. This is borne out by the histo-pathological studies and by the fact that the amount of nerve cell destruction in the various areas of the cerebrospinal axis correlates with the quantity of virus present. It appears,

therefore, that in experimental poliomyelitis injury and death of nerve cells is the outstanding lesion, and that the exudate is merely secondary.

One cannot always interpret the human disease in the light of the results obtained in experimental animals. In yellow fever, for example, the virus produces a generalized disease in humans and in monkeys, while in the mouse the disease is decidedly neurotropic. The manifestations of some other viruses also vary with the host.

The portal of entry in the human has been and still is the subject of considerable controversy. In the experimental animal the virus has a definite predisposition for the olfactory nerve, but we shall consider only those studies, which deal directly with the human.

Evidence to favor the nasopharynx as the portal of entry has been: (1) The epidemiology of the disease resembles in many respects a droplet disease. (2) The onset of the disease is often accompanied by upper respiratory symptoms. (3) The virus has been isolated from the mucosa and nasopharyngeal washings of acute cases, from the nasal excretions of normal and convalescent carriers, abortive and non-paralyzed cases. (4) Rarely has the virus been isolated from the gastrointestinal contents or its mucosa.

The gastrointestinal tract as a portal of entry has received considerable attention recently by Kling and co-workers in Europe and Toomey in this country. They have pointed out certain epidemiological aspects of the disease whereby it resembles a gastrointestinal infection and have also stressed the gastrointestinal symptoms that often accompany the onset. Important are the findings of Harmon⁹ who failed to find the virus in the nasopharyngeal washings of 20 cases but who found it in the gastrointestinal contents of 5 of these cases. Equally

significant was the failure to find lesions in the olfactory bulbs of 9 acute cases, a finding in keeping with that of Smith,¹⁰ who found lesions in only 25 per cent of 56 cases.

These conflicting data in the epidemiology and in the isolation of virus from the human body, should make one consider both portals of entry, especially as some epidemics start with nasal and others with gastrointestinal symptoms.

Direct evidence upon the route of transmission, based upon studies in the human is rather meager. The idea of a general dissemination either lymphogenous or hematogenous has received considerable support, especially from clinicians, based on the systemic manifestations of the disease frequently present prior to central nervous system symptoms. Medin stressed the pre-paralytic symptoms and described the so-called dromedary or diphasic type of the disease. Many pathologists have stressed the histo-pathological lesions found outside of the central nervous system. Rissler was one of the first and recently Smith¹⁰ has stressed their importance.

On the other hand, there are those who believe that the generalized symptoms can be explained entirely upon a central origin. The virus in travelling through the central nervous system can strike the temperature and vasomotor centers in the hypothalamus giving fever, gastrointestinal or upper respiratory symptoms, and other symptoms evident in early poliomyelitis. If in monkeys where the disease is entirely neurotropic one can have a systemic phase of the disease and even diphasic attacks,³ the same should be possible in the human.

Likewise, some believe that the lesions outside of the central nervous system are inconsequential, like those of any acute infectious disease. They may not indicate a proliferation of the virus

in these organs. Our own studies of 7 cases were in accord with this belief for we found but slight changes in the spleen, lymph glands, and thymus.

Attempts to obtain the virus from the blood stream have been negative. Likewise, the virus has been isolated from organs other than the central nervous system but once,¹ although the number of attempts have been relatively few. In our laboratory different tissues, including the liver, spleen, kidney, lungs, submaxillary glands, mesenteric lymph nodes and muscle from 3 cases were tested for the presence of virus. Large quantities of these tissues failed to produce poliomyelitis in monkeys, although infections were obtained with relatively small amounts of cord tissue from these cases.

It is hardly likely that the virus is carried by the cerebrospinal fluid, for our attempts and those of others have failed to reveal the presence of virus in it. Moreover, the pleocytosis may occur after the onset of nervous symptoms, or be absent, suggesting that the cells enter the sub-arachnoid space from

the cord. The increase in protein sometimes occurs after the pleocytosis, hardly likely if the meninges were involved earlier than the cord. Therefore, axonal transmission and primary involvement of the neurones, the latter suggested by Charcot and Jeffrey 65 years ago, must be considered, but is in need of further proof.

The presence of neutralizing bodies and resistance to the disease are not necessarily correlated:

IMMUNOLOGICAL STUDIES

When the virus of poliomyelitis is inoculated into a susceptible host, 2 changes can occur: one a resistance to reinoculation, the other the development of the so-called neutralizing substances. It was thought until recently that these correlated.

As has been recently pointed out by Schultz and Gebhardt^{11a} and Olitsky and Cox,^{11b} we have found that animals inoculated by the skin route with active or modified virus may develop neutralizing substances and yet fail to resist intracerebral inoculation of virus.

TABLE I

Monkey No.	Clinical Course	Intracerebral Reinoculation		Neutralization Tests	
		Time After Onset	Result	Time After Onset	Result

* — serum failed to neutralize

** + serum neutralized

Likewise, Jungleblut^{12a} and Sabin and Olitsky^{12b} have shown that recovered monkeys may resist reinfection, yet possess no serum neutralizing substances. Upon extending these studies, it was found that the serum of only 3 out of 8 convalescent monkeys, which were resistant to reinoculation, neutralized the virus although tested as long as 8 to 9 months after the onset of the disease (Table I). A number of investigators have shown that the sera of convalescent patients may fail to neutralize the virus. Recently we carried out an extensive study upon convalescent sera obtained from children admitted to the Willard Parker Hospital during the New York City outbreak in 1935.¹³ The sera of a large group of children, both paralytics and non-paralytics, were tested upon admission, that is, within a few days of the onset of the disease. A number of those individuals who failed to neutralize the virus, were retested at short intervals up to 8 or 9 months after the onset. The composite results given in Table II indicate that the majority of these children failed to develop neutralizing substances in their sera. Moreover, 14 out of 82 paralytics had neutralizing substances within the first few days of illness and 2 of these in the pre-paralytic stage. Harmon and Harkins¹⁴ also reported the presence of antibody in the serum of a patient tested

TABLE II
Summary of Neutralization Tests During First Year of Convalescence of Individuals Whose Sera Failed to Neutralize in the First Week

Age Groups Years	Paralytic		Non-paralytic	
	Number Tested	Number Neu- tralized	Number Tested	Number Neu- tralized
1-5	16	1	2	0
6-10	14	0	6	0
11-17	6	1	3	0
Adult	3	0	0	0
Total	39	2	11	0

in the pre-paralytic stage. One might say that these 14 individuals responded to the virus with antibody formation, very quickly. On the other hand, of 39 who lacked antibody upon admission, but 2 developed it within some months after the onset. This leads me to believe that poliomyelitis can develop in the presence of neutralizing substances.

ANTIBODY IS PROBABLY AN INDICATION OF IMMUNITY

From these data one may well inquire as to whether the presence of neutralizing substances is any indication of immunity. Up to the present time there is no such evidence in the experimental animal. This may be due to the fact that the level of neutralizing substances is not sufficiently high, or because the virus is neurotropic anti-

TABLE III

Summary of Neutralization Tests with Sera Taken in the First Week of the Disease and from Normals

Age Group in Years	Paralytics			Non-paralytics			Normals		
	Number Tested	Sera Neu- tralized	Sera Failed to Neu- tralize	Number Tested	Sera Neu- tralized	Sera Failed to Neu- tralize	Number Tested	Sera Neu- tralized	Sera Failed to Neu- tralize
1-5	26	2	24	6	1	5	96	5	91
6-10	25	4	21	14	10	4	38	11	27
11-17	19	4	15	10	5	5	25	19	6
Adults	12	4	8	2	2	0	13	7	6
Totals	82	14	68	32	18	14	172	42	130

bodies cannot reach it. In humans there is evidence to indicate that neutralizing substances correlate to some extent with immunity. The incidence of the presence of neutralizing substance is at the onset of the disease decidedly higher in non-paralytically, than in paralytically (Table III). There is even more evidence in individuals over the age of 10, of whom more than 50 per cent show neutralizing substances, very much like the so-called normals (Table III). This decidedly smaller proportion of paralytically, especially over the age of 10 who possess antibody as compared to non-paralytically, or normals, suggests that the neutralizing substances help to limit or prevent infection.

THE SPECIFICITY OF THE NEUTRALIZING SUBSTANCES

Do the above inconsistencies between the presence of neutralizing substances and resistance disprove the idea that the former is a specific response to the virus? In other words, does it respond only from exposure to the virus, or can it result from other factors as developmental changes such as Jungblut and Engle have suggested?¹⁵ It might even result from exposure or reaction to a related antigen.

There are certain factors in the epidemiology of the disease on account of which it is difficult to explain the presence of neutralizing substances in adults on the basis of sub-clinical immunization.¹ Moreover, the antibody is present in the sera of individuals who reside where poliomyelitis is almost absent.¹

On the other hand the distribution of the neutralizing substances in the sera of both urban and rural residents follows the trend of the Schick test and in diphtheria this immunity is well founded upon exposure.¹ It is absent from the sera of monkeys where the

likelihood of exposure to the virus is remote. We have been unable to demonstrate neutralizing substance in the sera of monkeys of different ages, nor were they resistant to inoculation.

Moreover the failure to develop neutralizing substances in convalescents does not distract from the idea of the specificity of the antibody. One can scarcely assign the inability of those affected with poliomyelitis to a general constitutional defect in view of the fact that so many monkeys may fail to show its presence in convalescence. Likewise it does not seem to be an inhibition of antibody formation for neurotropic viruses. To this end the sera of 10 convalescents, some known to have poliomyelitis antibody and some that lacked its presence were tested against a neurotropic herpes virus. There was no correlation, and convalescents who failed to develop poliomyelitis neutralizing substances showed herpes antibodies.

In other virus diseases, antibody may be absent in convalescence, and so its absence in poliomyelitis convalescents should not appear unusual. Its presence or absence may depend upon the amount of virus that leaves the central nervous system to reach the antibody depots. The occasional development of antibody more than a year after the onset may be the result of hyperimmunization.¹³

A very strong argument in favor of the specificity of the antibody is the fact that it has been produced experimentally, only after exposure to the virus.

THE TREATMENT OF POLIOMYELITIS

Prior to 1931 serum was generally recommended in the treatment of pre-paralytic poliomyelitis, despite the lack of statistically controlled data to prove its worth. As a result of two separate controlled studies carried out during 1931,^{16a, b} in which alternate cases

without paralysis were treated with serum, the mortality and paralysis rates were approximately the same for treated as untreated cases. In the experimental animal, where the disease is entirely neurotropic so that the virus contained in the central nervous system is walled off from the blood system by the Virchow-Robin spaces, extremely large doses of tested serum, of high neutralizing power, failed to affect the course of the disease.¹⁷ Serum or whole blood in 100 to 300 c.c. amounts was given intravenously at the onset of symptoms and in one instance during the incubation period.

Should human poliomyelitis prove to be a systemic disease with secondary localization in the central nervous system, can better results be obtained with larger amounts of more potent serum? This question may well be asked, since untested convalescent serum was used in the 1931 New York outbreak, and so many of the specimens making up the pools of sera probably lacked neutralizing antibodies. However, the diagnosis of poliomyelitis cannot be made until meningeal manifestations are apparent and then the central nervous system is already involved. At best the serum could only prevent more virus from entering the central nervous system. Little of it could pierce the blood-central nervous system barrier any more than can salvarsan. Any that pierced the barrier, broken down through inflammation, would be ineffective in preventing further spread of the virus, for a virus that is already fixed to cells can grow in the presence of its own antibody.

Various nonspecific treatments have been advocated and tried. Among these are repeated lumbar puncture or spinal drainage. It seems hardly likely that the increased flow of spinal fluid can wash out the virus that is already fixed to the nerve cells. Adrenalin, ephedrin, and hypertonic solutions have been

used to relieve the edema and congestion of the central nervous system, but without definite results. These measures may be of value in bulbar cases to relieve, temporarily, pressure upon the vital centers.

ACTIVE IMMUNIZATION

Because of the belief prevalent until recently that neutralizing substances were indicative of immunity to poliomyelitis, a considerable amount of the active immunity work in monkeys was gauged by the antibody response. Neutralizing substances have been produced in monkeys with skin inoculation of active virus,¹ virus-serum combinations,¹ attenuated¹ or germicidally treated, non-infected virus.^{11, 18} I have also reported that some¹⁸ animals which had received formalized virus were also resistant to intracerebral inoculation of virus. Other workers have failed to confirm this finding.¹¹ Whereas I used for the test dose what approximated a minimal infective dose of virus, these experimenters injected stronger doses. The reliability of such small doses has been questioned.¹⁹ Further investigation upon this subject leads me to believe that it is unwise to use such small doses of virus to test animals.

Both the ricinoleated virus used by Kolmer²⁰ and the formalized virus used by ourselves produced neutralizing substances in children. Children whose serum failed to neutralize in the control period, appeared to respond better than monkeys. Aycock and Hudson^{21a} and Kramer^{21b} found children in an epidemic area developed antibody within several months. The former tested sera from a group of children from an epidemic focus during the 1935 North Carolina outbreak who had received formalized vaccine and compared the findings with a group of non-vaccinated children. The tests were carried out just before vaccination and sera

were again obtained approximately 2 months after the first dose of vaccine. Of these whose sera failed to neutralize in the first test, 10 of 19 vaccinated and 9 of 31 controls had developed neutralizing bodies.

The children whom we tested were in a poliomyelitis free area, and the tests were carried out within 3 to 4 weeks after the administration of the vaccine. It seems likely, therefore, that the antibody response was due to the vaccine. Altogether, 10,000 children received formalized virus, but the number was too small to give information as to the value of the vaccine from a comparison of the incidence of the disease in the vaccinated individuals and the controls. A report by the Kern County health authorities, who vaccinated nearly 4,000 individuals in an epidemic area, concluded as follows: "Although the results are not statistically conclusive, they strongly suggest an actual immunizing effect from the Brodie vaccine."²²

The probability of obtaining an effective vaccine will depend upon several factors. In the first place should the human disease prove to be neurotropic as in the monkey, it will be difficult and perhaps impossible to develop a safe and effective vaccine. If, on the other hand, the human disease proves to be systemic, then by analogy with other diseases, a non-infective vaccine may produce immunity.

The measure of a person's reaction to the vaccine will be the presence of neutralizing substances. It will be necessary therefore to carry out further work with a view of determining the relationship of the presence of antibody to resistance to the disease. It will also be necessary to determine whether or not susceptible individuals are capable of producing neutralizing substances. The need for a susceptibility test is quite obvious.

The practical application of a vac-

cine will be in a large measure determined by whether a single or multiple strains exist. If multiple strains that are unrelated immunologically exist, it will be hardly feasible to prepare a polyvalent vaccine. Until recently the evidence has been that differences in strains were quantitative—that is, the results of differences in virulence. Recently several investigators have reported that qualitative changes exist. In our studies upon 3 strains, we found that one was almost identical with the passage strain and that the other two differed qualitatively. One must bear in mind the possibility of only one strain existing in the human, but that virus specimens can be modified in passage through the monkey. There is evidence of this in other virus diseases.

NASAL SPRAYS AS A METHOD OF PREVENTION

Tannic acid, alum, silver nitrate and other astringents²³ applied to the nasal mucosa protect monkeys against intranasal instillation of virus. Although the exact mechanism by which these substances can protect monkeys from intranasal infection is not definitely known, it is believed that they protect the olfactory nerves from the virus. The method was applied to humans in the summer of 1936 in Alabama by Armstrong of the U. S. Public Health Service,²⁴ but the results were not encouraging. Armstrong felt that the failure was due in part to improper application of the spray.

On the other hand, there are other reasons which speak against the probable success of the nasal spray as a means of prevention in children, although it protects monkeys against nasal infection. Due to frequent blowing and picking of the nose, and other forms of trauma to the mucosa of children, the applications may not last sufficiently long to serve as a successful barrier, or the irritation produced may

weaken the olfactory barrier if the virus travels along the olfactory nerve. Secondly, the spray can be administered to young children only with difficulty. Even more important is the possibility that the virus may not travel along the olfactory nerves. It would seem more logical, therefore, to elucidate the portal of entry and path of the virus and let the future use of the nasal spray be guided by the results.

CONCLUSIONS

1. The virus of poliomyelitis in the experimental animal is strictly neurotropic and travels by way of the nerve tracts.
2. Neither the portal of entry nor the pathogenesis has been finally determined in the human. Therefore one cannot draw too close an analogy between the experimental and human diseases, nor apply all experimental results that bear upon the portal of entry and pathogenesis to the human.
3. The immunological data were studied upon which the following conclusions can be stated:
 - a. The presence of serum neutralizing substances or the so-called antibodies and resistance to the disease do not necessarily correlate. However, in the human there is evidence to believe that the presence of antibody may be indicative of immunity.
 - b. Recovery from poliomyelitis does not, as a rule, result in demonstrable antibodies or neutralizing substances.
 - c. The so-called neutralizing substance can develop only as a result of specific exposure to the virus.
 - d. There is evidence to believe that more than one strain of virus exists.
4. Neither convalescent serum nor any of the other available measures of treatment that have been advocated offer any hope for the prevention or limitation of paralysis in treated cases.
5. The value of active immunity as a preventive is undetermined. Further studies should be withheld until the human pathogenesis has been worked out; also further immunology, especially upon the question of strains.
6. Nasal sprays are effective in protecting the monkey. In the human the results are not encouraging and the reasons are discussed for believing that they may not protect the human.

International Nursing Scholarships

THE establishment by the Central Committee of the American Red Cross of two scholarships to be awarded annually over a period of 5 years to an American nurse and to a nurse from another country to attend the courses offered by the Florence Nightingale International Foundation in London, England, was announced by Ida F. Butler, National Director of the American Red Cross Nursing Service, at the opening session of the National Nursing Biennial Convention, held in Kansas City, Mo., April 25.

The scholarships are established in memory of Clara Dutton Noyes, who served as director of the Bureau of Nursing of the American Red Cross during the World War, and as National Director of its Nursing Service from 1919 until the time of her death in 1936.

The Florence Nightingale International Foundation represents a living memorial to Florence Nightingale, the founder of modern nursing, and offers nurses everywhere an effective method of working specifically for peace through understanding. Inaugurated in 1934, by the League of Red Cross Societies and the International Council of Nurses, the Foundation provides an endowed trust for postgraduate education in public health nursing, and teaching and administration in schools of nursing at Bedford College, London, in coöperation with the British College of Nursing.

Almost 400 nurses from 47 countries of the world have taken the courses which are now under the aegis of the Florence Nightingale International Foundation. Seven of them have been American nurses.

Rural Syphilis—A Localized Outbreak

R. C. KIMBROUGH, M.D., D. M. COWGILL, M.D., F.A.P.H.A.,
AND E. P. BOWERMAN, M.D.

Monroe County Health Unit, Madisonville, Tenn.

IN Monroe County, Tenn., there occurred an episode which it is believed illustrates some of the important factors in the control of syphilis in rural areas.

Monroe County is situated in the extreme eastern part of the state. It is almost entirely rural and the population is 95 per cent native white.

In July, 1935, a boy from a CCC camp was discharged because he had syphilis. He had had sufficient treatment to render him supposedly non-infectious, namely, 5 doses of neosalvarsan and 5 doses of bismuth. He was presumably told that he would need further treatment before he would be cured.

The County Health Department was notified of the boy's discharge and treatment status. He did not report to the health department nor could he be found by the department, due to his going to another part of the county under an assumed name.

In October, 1935, he suffered a relapse, having mucous patches, condylomata and a skin rash, and reported to a physician for treatment.

Before applying for treatment he had directly infected 2 and directly or indirectly a 3rd rural prostitute.

The private physician whom the patient consulted explained to him the nature of the disease, and since that time he has been faithful in taking treatments. He also revealed the names of his contacts after his return

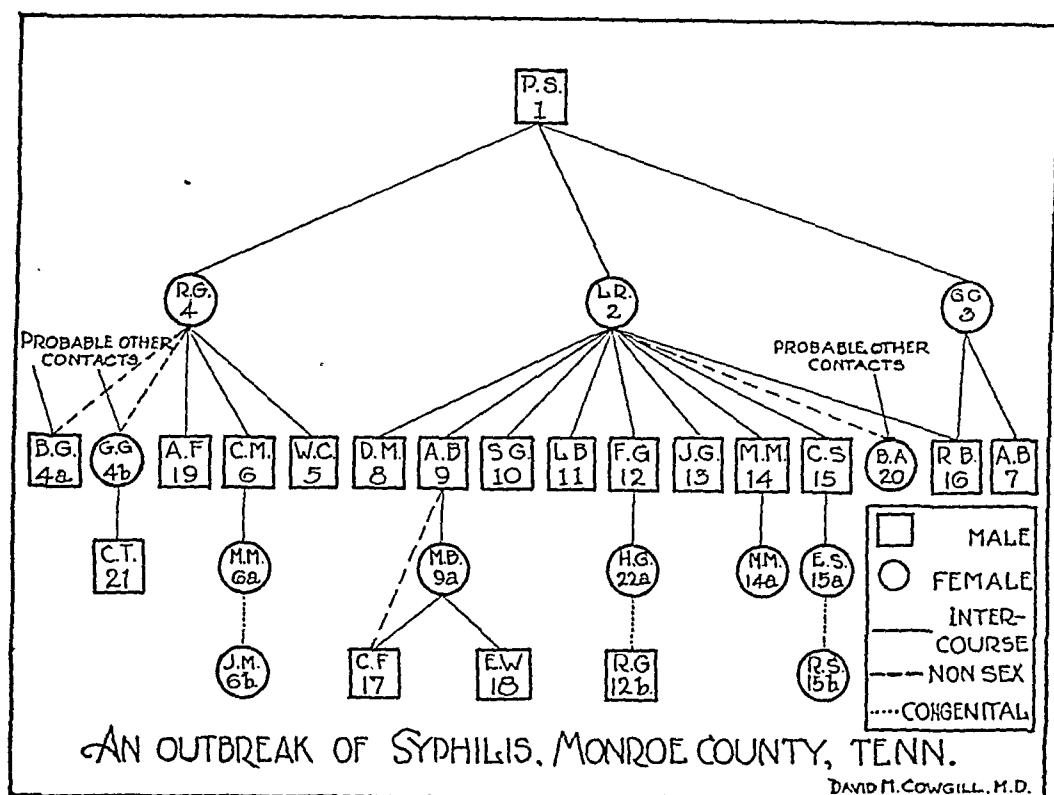

to the county to the physician who reported the case and contacts to the health department. The physician assisted in locating the contacts, and treated some of them as private patients.

The 3 girls with whom he had had contact were found and brought under treatment. All of the known contacts of these girls, some 23, were examined. Of these, 7 were negative and 16 positive. Three of the positive had other possible source of contacts. After being brought under treatment there were no further cases traced to these 3 girls until one of them discontinued treatment. She had an infectious relapse and infected 1 person. This lapse in treatment occurred in spite of repeated instruction as to the nature of the disease.

Since January, 1937, no further cases have been traced to this source. Now, February, 1938, it is possible that after the completion of the treatment of the last cases this epidemic will be closed. It is too early to be certain of this since 3 cases relapsed after having as many as 20 doses of neosalvarsan plus heavy metals, and infected other people.

Among those who have contracted the disease directly or indirectly from this source were 4 wives who were infected by their husbands. One daughter contracted the disease from her father and spread it to 2 other men.

The accompanying chart shows the

method of spread from the original case to the other persons. In some cases, contacts were 4 steps removed.

The spread of the disease may be considered as having 4 phases:

1. The initial case and his infection of 3 prostitutes
2. The spread contacts of the 3 prostitutes
3. The passage of the disease from those infected by prostitutes to others, principally family contacts
4. The ultimate bringing under control of all cases with the close of the episode and cessation of spread of the disease.

This episode is a minor one in the history of syphilis, but it illustrates dramatically the steps which must be taken to eliminate syphilis from a rural county.

CONCLUSIONS

1. The careless, ignorant, transient may cause epidemics of syphilis in his wanderings. When this type of person is found to be infected, he should be rigidly controlled by some agency.

2. The general practitioner is a very important element in the attack on syphilis. As in this case, the patient usually goes to the private physician first. Realizing the importance of the situation, the physician in this case obtained the names of the contacts and was instrumental in seeing that both the original case and the infected contacts were effectively treated.

3. Infected persons will usually give the names of contacts when questioned tactfully. These contacts, familial and extra-familial can be found if looked for and brought under treatment if infected. If they are treated with consideration they will usually continue their treatments.

4. Infectious relapses occurred even after as many as 20 doses of neosalvarsan plus heavy metal therapy. It is not believed that these were new infections.

5. When the main sources of infection in this particular episode were

found and kept under treatment, it came to a close. This came about because of the joint efforts of the private physician and the health officer.

If all cases of syphilis were studied

from the standpoint of finding the sources and the contacts located and put under adequate treatment, syphilis would become a rare disease in the rural areas in a short time.

Housing Survey

ACCORDING to the Preliminary Report of the National Health Survey on "Adequacy of Urban Housing in the United States as Measured by Degree of Crowding and Type of Sanitary Facilities":

Three million urban families in the United States have fewer rooms in their homes than there are persons; one million live in dwellings with more than one and a half times as many persons as there are rooms; 700,000 live in dwellings with at least twice as many persons as there are rooms.

These estimates for urban families are based on figures obtained in the National Health Survey, 1935-1936, for a representative group of 83 cities. The number of persons in 740,000 urban households was recorded and also the number of rooms which any group occupied. Thus it was possible to calculate the number of persons per room for each of these households. . . .

The data at least suggest that in all parts of the country families on a fairly high economic level secure adequate housing. This is especially true with respect to any judgment of adequacy based on the type of sanitary facilities. It is among the relief and other low income groups, especially in the colored population, that the greatest variation occurs. For such groups the kind of sanitary facilities available varies greatly, depending on the part of the country and the size of the city in which they live, as well as on many other factors. . . .

Data have been collected in a project conducted by the U. S. Public Health Service, with the aid of financial grants from the WPA, in a house-to-house canvass of about 800,000 families including 2,800,000 persons in 83 cities, and 23 rural areas in 19 states.

Lactobacillus Acidophilus and Dental Caries*

PHILIP JAY, D.D.S.

School of Dentistry, University of Michigan, Ann Arbor, Mich.

DENTAL caries, due to its widespread distribution and steadily increasing incidence, is worthy of the serious attention of students of public health problems. It is the purpose of this report to emphasize a few established facts in the hope that a clearer concept may be had of the etiology and control of the disease.

At the turn of the century W. D. Miller¹ advanced the hypothesis that there is present in the saliva an acidogenic substance which is responsible for the initial decalcification of enamel. He demonstrated that this substance was bacterial in origin. Inasmuch as a variety of organisms which may be responsible for the breaking down of carbohydrates is found in the mouth, it was Miller's belief that no one specific microorganism but that several acidogenic types were responsible for caries. It became more clearly understood that although Miller's theory was substantially reasonable, it was true that acidogenic bacteria can also be demonstrated in the mouths of caries-free individuals with the greatest regularity. More recently² it has been shown that although acid producing coccal forms and yeasts may inhabit the mouth with no apparent danger to the teeth, the

presence of lactobacilli is invariably associated with caries. A renewal of caries activity in susceptible patients was always presaged by a marked increase of the oral lactobacilli as determined by quantitative culture of the saliva, while a drop in the lactobacillus count always signified an arrest of caries.

These findings were not very enthusiastically received since various investigators both at home and abroad were reporting the successful control of the disease by dietary means. All claimed beneficial results, but their theories as to how these results were obtained were in conflict with each other. Vitamins A and D were claimed to be specific anti-caries factors by some, while others were equally convinced that caries was a vitamin C deficiency disease. It was reported also that caries resulted from a deficiency of phosphorus and calcium in the diet. These theoretically dissimilar experimental diets were producing more or less satisfactory results. It might be inferred, therefore, that the enamel of the tooth is an unstable structure and that it is dependent for its maintenance on a variety of food factors, the absence of one or more of which results in caries. Such an inference is false, since histologically the enamel is extremely stable. At the time of the eruption of the tooth, the enamel con-

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

tains neither enamel forming cells nor a demonstrable circulatory system. In this respect the tissue is atypical and it is extremely doubtful if matured enamel can respond to metabolic influences. Furthermore there is no factual evidence that the structure of the tooth is of major importance in dental caries.

Notwithstanding these apparent inconsistencies, the disease is in a measure controllable by diet. It would appear, therefore, that the experimental diets each contained a factor in common which, unknown to the investigator, was actually responsible for the beneficial result. Studies conducted in the School of Dentistry* of the University of Michigan indicate that the carbohydrate element in the experimental diets was such a factor. This possibility was brought to our attention because of the unusually low incidence of caries in an experimental group of children on a diet deficient in vitamins and minerals but almost completely sugar-free. In other words, caries was reduced on a diet that was not even suitable for normal growth and development. When large amounts of sugar in the form of candy were included in the diet, new caries soon appeared, and we observed an increase in caries when an excess of sugar was added to diets nutritionally adequate. This is explainable by the fact that the number of oral lactobacilli is proportionate to the amount of carbohydrate in the diet. Lactobacillus counts were made to rise and drop at will by increasing and restricting the amount of sugar and starch in the diet. Sugar was restricted to a greater or lesser extent in all of the beneficial diets referred to. No particular significance was attached to sugar by any of these authors other

than the supposition that artificially sweetened foods were too often consumed at the expense of nutritional necessities. Whether or not these bacteria are actually the sole cause of the disease is of academic importance. Of more immediate significance is the fact that they bear a diagnostic relationship to caries. Through quantitative estimations we were able to demonstrate that dental caries is not related to the nutritional adequacy of the diet and that the proprietary mineral and vitamin preparations being sold for the prevention of the disease are entirely ineffective.

The method used in making the quantitative lactobacillus estimation is similar to that described by Hadley.³ In order to obtain uniform volumes of saliva, the subject is instructed to chew a small piece of paraffin making it a point to shift it from one side of the mouth to the other so as to dislodge as much of the detritus from the tooth surfaces as possible. As the saliva is accumulated in the mouth it is expectorated into a large sterile tube. Three minutes is arbitrarily selected as the time for collecting the specimen. The specimen is thoroughly shaken, after which 0.1 c.c. of it is spread evenly over a tomato agar plate with a glass spreader. Glucose acid broth is also inoculated as a qualitative check. After a 4 day incubation the number of organisms per c.c. of saliva is estimated by multiplying the number of *L. acidophilus* colonies on the plate by 10.

The tomato agar used is a modification of Kulps medium, prepared in the following manner:

Mixture A—Add 10 gm. of Difco peptone and 10 gm. of Difco peptonized milk to 400 c.c. of juice filtered (through cotton) from a good quality of canned tomatoes. Heat gently to dissolve the peptone and peptonized milk. Unnecessary heating of the tomato juice should be avoided. The reaction of the solution is adjusted to pH 5.0 with lactic acid.

* The dental caries studies of the Michigan group were supported by grants from the Children's Fund of Michigan and The Horace H. Rackham Foundation.

Mixture B—Add 25 gm. of dried agar to 600 c.c. of distilled water and autoclave to dissolve the agar. Just before removing B from the autoclave, bring A to the boiling point. Then mix A and B while both are hot and filter through a thin layer of absorbent cotton. Distribute in containers and sterilize by heating in the autoclave at 120° C. for 8 minutes. The properly prepared medium is a clear agar, of a light brown color, having a final reaction of pH 5.0.

One disadvantage of this technic is the difficulty of obtaining uniform samples of saliva. At best, cultures so taken give but an approximate indication of the actual number of organisms on the tooth surfaces. Consequently before attempting to reduce the oral lactobacilli through dietary change, preliminary counts on 3 successive days are made to determine the average count. It is important to obtain these samples at the same time of day for each individual and never immediately after a meal since the number of bacteria in the saliva always falls after eating.

In the treatment of severe dental caries the patient is first placed on a diet in which the carbohydrate is moderately restricted. This usually involves the omission of all forms of confection, cake, pie, ice cream, and other artificially sweetened desserts. A lactobacillus count is made after 2 weeks, and if there has not been a precipitous drop more severe dietary restrictions are made. Occasionally it is necessary to resort to a typical high fat diabetic diet. These cases require intelligent handling by physicians with a thorough knowledge of dietetics. Although we have reason to believe that an adequate diet is not necessary for the prevention of dental caries it is of course essential for normal growth and good health.

The carbohydrates cannot be casually stricken from the diet without regard for the caloric requirement of the patient. By trial and error a diet is finally found on which the lactobacillus counts become negative or only sporadically positive. By this method caries activity was arrested in about 80 per cent of the cases under observation. A few of the highly susceptible patients have continued to have lactobacillus overgrowths despite the most drastic dietary treatment. There are some individuals, comprising about 3 per cent of our population, who seem to be immune to dental caries. Their cultures, both saliva and stool, are consistently negative for lactobacilli even when they consume candy and other sweets in excess.

Summarizing, the studies conducted by the Michigan group indicate that:

1. Dental caries activity is not related to the nutritional adequacy of the diet.
2. The disease is not arrested by supplementing the diet with mineral and vitamin preparations.
3. A diagnostic relationship exists between the growth of oral lactobacilli and dental caries activity.
4. The number of oral lactobacilli is proportionate to the amount of carbohydrate in the diet.
5. Rampant dental caries can be effectively treated by restricting the carbohydrate in the diet.

Survival of *E. Typhi* in Sewage Treatment Plant Processes*

CARL E. GREEN, F.A.P.H.A., AND PAUL J. BEARD, PH.D.

State Sanitary Engineer, Portland, Ore.; and Associate Professor of Sanitary Sciences, Stanford University, Calif.

THE importance of typhoid fever as an epidemic disease has apparently diminished during recent decades, but it is wise to remember that typhoid has neither been eliminated nor conquered. Barriers have been placed around it to prevent its spread, but its menace is ever with us. The survival of intestinal pathogens in water and sewage has been the subject of study for many years since the early work of Jordan, Russell, and Zeit¹ in 1904. Edwards² in 1930 reviewed the research of various French and German investigators. Heukelekian and Schulhoff⁶ in 1935 presented a comprehensive historical review of the literature which need not be repeated here. The difficulties in the way of quantitative investigations have until recently been insuperable. Wilson and Blair^{3, 4} reported success using a bismuth sulphite medium. Ruchhoft found the original Wilson-Blair medium too inhibitive for *E. typhi* in his work for the Sanitary District of Chicago; subsequently he modified the media and reported more successful isolations. Heukelekian and Schulhoff⁶ in 1935 reported the de-

velopment and use of a brilliant green nutrient agar medium.

In the investigations described in this paper, Difco bismuth sulphite medium[†] was used. One ml. portions of proper dilutions made up with physiological saline solution were added to the solidified pour plates and spread uniformly over the surface of the medium by means of a sterile needle, care being taken to prevent any portion from reaching the outer edge and running down between the medium and the glass plate. Plates were then dried at about 40° C. and not exceeding 45° C. in a glass-top open bottom box provided with side ventilation holes. Incubation for 36 to 48 hours was required for best plate counts. *E. typhi* colonies on this medium have a dry, jet black color, button-like appearance, and are frequently surrounded by a metallic halo. Most sewage organisms are so successfully inhibited as to cause negligible interference.

A. ISOLATION OF *E. TYPHI* FROM RAW SEWAGE

During January, February, and March, 1937, 9 samples of Palo Alto, Calif., raw sewage were examined for *E. typhi*. Of a total of 55 1 ml. por-

* Abstract of a paper read before the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

tions plated in this group, 9 positive isolations were made from separate 1 ml. portions. Four samples collected in May, 1937, were plated but no successful isolations were made in the 21 1 ml. portions examined.

During February and March, 3 samples of raw San Francisco sewage entering the Golden Gate Park activated sludge plant were plated about 18 hours after collection. No typhoid

bacilli were isolated from the 23 1 ml. portions examined.

B. STUDIES OF THE SURVIVAL OF E. TYPHI IN RAW SEWAGE

Two liter portions of raw Palo Alto sewage were placed in 2 2½ liter wide-mouth glass jars fitted with rubber stoppers in which inverted U tubes were placed for ventilation. They were then inoculated with a 24 hour agar culture

of Rawlings' strain of *E. typhi*, one having an initial *E. typhi* count of 6,500,000 per ml. and the other 5,000,000. One jar was kept at room temperature exposed to north light and the other was placed outdoors exposed to sunlight during a part of the day. The contents of each jar was thoroughly mixed before sampling.

Table I shows that 11 per cent of the typhoid organisms stored at room temperature survived for 3 days. At 7 days only 0.1 per cent remained, but positive isolations were made in 1 ml. portions through the 19th day.

Typhoid organisms in sewage stored outdoors at lower temperature survived for a longer period. Positive isolations from 1 ml. were made through the 27th day. The pH range (7.2 to 7.8) in each instance was not unfavorable.

C. SURVIVAL OF *E. TYPHI* UNDER CONDITIONS SIMULATING A SEPTIC TANK

Two liters of raw Palo Alto sewage plus 400 ml. of fresh sludge were placed in each of two jars, as under B; *E. typhi* were added and the jars stored in a hood at room temperature without being exposed to sunlight. Samples were taken from the relatively clear liquor between the scum and sludge of one container and from the mixed contents of the other.

The data in Table II reveal little difference in typhi counts in the supernatant and mixed samples up to the 4th day, when only 2 per cent remained in either case. In all but 2 instances, more typhoid bacilli were found in the mixed portions. Successful isolations in 1 ml. were made in the supernatant for 24 days and in 0.1 ml. portions of the mixed sewage for 27 days.

D. SURVIVAL OF *E. TYPHI* IN ACTIVATED SLUDGE

In the following experiments, activated sludge was collected from the San Francisco Golden Gate Park plant

and aerated in the laboratory by means of glass diffusers set in wide-mouth glass jars. Activated sludge was mixed with raw Palo Alto sewage. *E. typhi* counts were made on unsettled samples.

1. Activated sludge collected one evening was allowed to stand over night and the supernatant replaced by raw sewage. After aeration for 24 hours followed by settling, the supernatant was replaced with raw sewage, *E. typhi* added to give an initial count of 37,500,000 per ml., and the experiment started. An *E. typhi* reduction of 91 per cent in 6 hours, 95 in 8 hours, and 99.9 in 24 hours of aeration was observed; the pH rose from 6.8 to 7.6 in the first 4 hours.

2. Four liters of activated sludge in a 4½ liter jar were aerated for 5 days, fresh raw sewage being used to replace the supernatant on the 2nd and 4th days. On the 5th day, *E. typhi* were added and aeration continued for 6 days; the pH remaining at 6.4. *E. typhi* counts showed a reduction of 96 per cent in 6 hours and 99 in 8 hours.

3. In an experiment similar to the one described under 2, aeration was maintained for 2 days prior to the addition of *E. typhi*; with no raw sewage added the pH dropped to 6.0. A 97 per cent reduction in *E. typhi* was indicated in 6 hours and 99 in 8 hours. As in the previous studies, a few organisms survived several days of aeration.

TABLE VI

Survival of E. Typhi in Activated Sludge at pH 7.4

Aeration Time	Temp. ° C.	pH	<i>E. Typhi</i> per ml.	Per cent Surviving
0	17.5	7.4	45,000,000	..
1 hr.	13,000,000	29
2 hr.	5,000,000	11
3 hr.	1,800,000	4
4 hr.	18.5	7.4	900,000	2
5 hr.	400,000	0.9
6 hr.	18.5	7.4	375,000	0.8
7 hr.	260,000	0.6
8 hr.	18.5	7.4	175,000	0.4
24 hr.	17.5	7.4
2 days	15	7.4	14,500	0.03
3 days	16.5	7.4	9,000	0.02

4. In an experiment using the same batch of activated sludge as under 3, with raw sewage added once each day, the pH was constant at 7.4. In 6 hours a reduction of 99 per cent in *E. typhi* numbers was noted (see Table VI and Chart VI).

5. A study was next made of the effect of protozoa and non-spore-forming organisms on the survival of typhoid organisms in activated sludge. A sample of fresh activated sludge was thoroughly mixed with raw sewage and divided into equal 2 liter portions. One portion was then autoclaved at 80° to 95° C. for 20 minutes and water cooled to room temperature immediately thereafter. *E. typhi* were added to both and aeration started.

The results shown in Table VII and Chart VII are of interest. The pH of the heated sludge continued to rise throughout the 6 day aeration period; after the 1st day it dropped in the control jar. In the heated mixture an increase in *E. typhi* was observed for 3 days; a very abrupt reduction followed. The increase in typhoid organisms may have been caused by some hydrolysis of organic matter which furnished food, or by the lack of competitive and predatory types of organisms or both. In the control only 1 per cent survived 6 hours of aeration. After 4 days of aeration very little difference was noted in the per cent surviving in either container. This experiment seems to suggest rather definitely that biological

activity and not aeration *per se* is responsible for the reduction of typhoid organisms in the activated sludge process.

E. TRICKLING FILTER STUDIES

A search of the literature having failed to reveal any data on the survival of typhoid organisms in sewage during passage through a trickling filter, it was decided to investigate the behavior of typhoid organisms undergoing

TABLE VII

Survival of E. Typhi in Heated and Unheated Activated Sludge

6 days	17.5	6.0	160	0.0003	17.5	8.4	10,000	0.02

this type of treatment. Accordingly, an experimental unit was constructed at the Palo Alto sewage plant. A filter was made up of a 6½', 24" diameter section of galvanized, corrugated iron culvert pipe set on a grid of 2 by 4's nailed on edge, spaced ½" apart, and supported by 8 by 8's. A galvanized sheet-iron tray collected the filter effluent and permitted free air movement to the underdrains. A rotary distributor having ½" diameter

arms drilled with 3/16" holes was mounted on a ¾" riser pipe. Six feet of 1¼"-2½" sound, blue, crushed rock was used. The distributor revolved 3" above the surface of the rock and was driven by a variable speed motor.

Palo Alto clarifier effluent was conveyed to a variable capacity gear pump by a 1" pipe fitted with a 14 mesh screen. A tee connection and needle valve on the suction side of the pump permitted the addition of typhoid broth

cultures. To allow for sedimentation, collection of composite samples and chlorination when desired, a 15 gal. steel tank 22" in diameter was used to receive the filter effluent.

The filter was placed in operation with constant dosing for a period of 1 month before experiments were started. B.O.D.,* D.O., N, settleable solids,

of about 300 p.p.m. and a pH of 7.2-7.4. The filter effluent contained from 5 to 8 p.p.m. D.O. and had a pH of 7.8-8.0. Solids which were not unlike activated sludge in appearance continually sloughed from the trickling filter. Filter flies bred constantly during the test runs.

1. Constant Dosing at Rate of 3.6 m.g.a.d.†

A broth culture of *E. typhi* was added to the sewage for 3 hours and counts made at intervals shown in Table VIII. The data secured and the curves plotted on Chart VIII indicate a reduction of about 99 per cent with influent and effluent curves being practically parallel. During the experiment a B.O.D. of 220 p.p.m. was reduced 75 per cent as measured by a settled effluent composite sample. In the tests which follow, B.O.D. reductions were determined by the same method, but in all instances *E. typhi* counts were made of the unsettled filter effluent.

2. Constant Dosing at Rate of 5.4 m.g.a.d.

As under 1, typhoid organisms were ap-

TABLE X

Survival of E. Typhi in Trickling Filter—Constant Dosing—6.6 m.g.a.d.

Time	Influent			Effluent

Influent B.O.D. = 300 p.p.m.

Effluent B.O.D. = 50 p.p.m.

oxygen consumed, and stability determinations were made to check filter efficiency during the period in which the filter-bed was built up. Palo Alto sewage is strictly domestic except for the waste from one cannery, has a high B.O.D., no D.O., and about 5 p.p.m. H₂S. The settled sewage had a B.O.D.

plied for 3 hours and counts made at frequent intervals. Over a 4 hour period typhoid numbers were reduced about 96 per cent. A 75 per cent reduction of the 260 p.p.m. B.O.D. was obtained.

3. Constant Dosing at Rate of 6.6 m.g.a.d.

Data secured in this experiment and listed in Table X are interesting for two reasons: (1) a 99 per cent reduction of typhoid organisms was secured, and (2) the correlation between effluent and influent *E. typhi* counts

* B.O.D. = biochemical oxygen demand
D.O. = dissolved oxygen
N. = nitrogen

† m.g.a.d. = million gallons per acre per day.

was very marked although the number of organisms varied considerably. The B.O.D. of 300 p.p.m. was reduced 80 per cent.

4. Constant Dosing at Rate of 12 m.g.a.d.

In a run at high dosing rate for 1 hour, it was surprising to obtain an *E. typhi* reduction of about 95 per cent.

5. Intermittent Dosing Cycle—Rate 1 m.g.a.d.—2 Minutes Dosing Followed by 6 Minutes Resting

In this experiment 5,500,000 *E. typhi* per ml. were added for 2 minutes and the filter operated on above cycle. The B.O.D. was 300 p.p.m. and a 75 per cent reduction was secured. *E. typhi* were recovered in the effluent in 0.1 ml. portions up to 1 hour and 6 minutes, but the highest count at any time was only 30 per ml. Composite samples collected at ½, 1, and 2 hour intervals contained only 10 typhoid organisms per ml.

6. Intermittent Dosing Cycle—Rate 1.4 m.g.a.d.—4 Minutes Dosing Followed by 6 Minutes Resting

A concentration of 650,000 *E. typhi* per ml. was added for 1 minute and effluent samples plated over a 2 hour period. The sewage B.O.D. of 350 p.p.m. was reduced 85 per cent. Viable organisms were recovered in 0.1 ml. portions in only 2 of 12 samples;

in none of the ½, 1, or 2 hour composite samples of the effluent.

7. Intermittent Dosing Cycle—Rate 1.7 m.g.a.d.—3 Minutes Dosing Followed by 3 Minutes Resting

E. typhi were added for 2 minutes in a concentration of 1,000 per ml. No recoveries were made in the effluent in 0.1 ml. portions. The sewage B.O.D. was 190 p.p.m. and a reduction of 80 per cent was secured.

8. Intermittent Dosing Cycle—1.5 m.g.a.d. Rate—3 Minutes Dosing Followed by 7 Minutes Resting

To add typhoid bacilli to the sewage over an extended period during intermittent dosing, it was necessary to open and close the needle valve between the flask of organisms and the

Effluent B.O.D. = 40 p.p.m.

pump each time the motor was started and stopped. *E. typhi* counts therefore varied considerably as shown in Table XV. A reduction of 85 per cent in the 270 p.p.m. B.O.D. of the sewage was obtained. Chart XV shows a consistent reduction of about 99.9 per cent.

9. Intermittent Dosing Cycle—2.8 m.g.a.d.
Rate—5 Minutes Dosing Followed by 10 Minutes Resting

In this experiment a B.O.D. reduction of 70 per cent was secured with a sewage strength of 400 p.p.m. The addition of

SUMMARY AND CONCLUSIONS

1. Use of the highly selective modified Wilson-Blair bismuth-sulphite medium makes quantitative studies of the behavior of *E. typhi* in sewage and sewage treatment processes possible.

2. Successful isolations of *E. typhi* in 1 ml. portions of raw Palo Alto sewage were made in several instances. The isolation of viable typhoid organisms in the sewage of a city having

< = less than

Influent B.O.D. = 400 p.p.m.

Effluent B.O.D. = 110 p.p.m.

E. typhi and the dosing cycle were manually controlled. Data in Table XVI plotted on Chart XVI show influent and effluent counts parallel with a reduction of about 99.9 per cent.

a high standard of sanitation and without having had an outbreak of typhoid fever in 30 years emphasizes the need for constant vigilance if effective barriers are to be maintained between infectious material and susceptible hosts.

3. The findings of early investigators on the longevity of the typhoid bacillus in sewage has been confirmed, it having been shown that a rapid decrease occurs for 3 or 4 days, after which survivors may persist for several weeks. The influence of temperature was noted as by other investigators, sur-

vival time being longer at lower temperatures.

4. Under conditions simulating a septic tank, it was found that 2 or 3 per cent of the typhoid organisms survived for 4 days both in the supernatant and in the mixed contents of the container. After the 4 day period, there were fewer survivors in the supernatant, though they were isolated in 1 ml. portions for 24 days. They were still found in 0.1 ml. portions of the mixed sludge, scum and supernatant through 27 days.

5. Experiments with activated sludge indicate that a reduction of 90 to 99 per cent in typhoid organisms can be expected during 6 hours aeration, and that in most instances only 1 to 3 per cent will survive. An experiment with activated sludge heated sufficiently to destroy or inactivate protozoa and non-spore-forming bacteria, indicated that biological activity and not aeration *per se* is responsible for the reduction in *E. typhi* in activated sludge. An increase of *E. typhi* occurred during 3 days of aeration of the previously heated sludge. A control batch showed a normally expected decrease during the same time.

No tests were conducted on the survival of *E. typhi* during the digestion of activated sludge.

6. In the studies herein reported, a trickling filter operating intermittently at effective rates up to 2.8 m.g.a.d. removed 99.9 per cent of typhoid organisms in sewage. Reductions of 96 to 99 per cent were secured at constant

dosage rates up to 6.6 m.g.a.d. and a 95 per cent reduction at 12 m.g.a.d. With alternate dosing and resting cycles, high concentrations of typhoid organisms were added for 1 or 2 minutes with but few viable organisms passing through the bed.

Considering the possibility of sampling errors involved in experimental work of this kind, the data secured seem surprisingly consistent and the curves of *E. typhi* counts in the influent and effluent are reasonably parallel, allowance being made for lag in passage through the filter.

It is apparent that two commonly used processes for secondary biological treatment of sewage, namely, activated sludge and trickling filtration, may be expected to reduce greatly typhoid organisms present in sewage, and are, therefore, effective barriers for the protection of public health.

AN AMERICAN MUSEUM OF HEALTH

FOR nearly eight years the Association's Committee on American Museum of Hygiene has been moving steadily toward its goal, the establishment of the first of a series of permanent Museums of Health in this country. As is usual with those who advance new ideas and new methods, the committee has been forced to make capital of small gains and to work often without a great deal of encouragement. There are evidences now of their patient efforts coming to fruition.

The idea brought forward again and again by the committee is catching on—that the museum concept is readily adaptable to the education of the public in matters of health, that it provides a new and different approach to the problem of teaching the average man and woman the facts about their own physical organization, the personal application of medical and public health progress, and the way to better and more healthful living. The essence of the museum method of teaching is pictorialization and illustration, the capturing of dramatic facts which are now buried in verbiage in most of our health education programs and consequently remain misty abstractions in the public mind. It is, of course, the exhibit method on a grand scale, but the coördinated, unified exposition of man and his health at which the committee aims, moves into focus not a function nor an organ nor a specific health hazard as many health exhibits do, but the whole man and his environment.

The museum of health, as a new instrument for health education in this country, has passed successfully the acid-test of investigation of those who have money to give. The Oberlaender Trust, the Carnegie Corporation, and the Josiah Macy, Jr. Fund have considered the objectives of the Committee on American Museum of Hygiene worthy of financial support, thus giving great impetus to its work.

With the opening of the New York World's Fair, 1939, the public and the medical and public health professions will have the opportunity to see the first flowering of the committee's plans. A Medical and Public Health Building, the first ever to be set aside at a World's Fair in this country for exhibits in this field, is an important part of the exposition "Building the World of Tomorrow."

and for its existence the committee is largely responsible. The Fair was a challenge to the committee as a time and place to do a tremendously effective job in mass health education and at the same time to lay the groundwork for a permanent museum. The thought throughout in the development of the Medical and Public Health Building has been that the exhibits would be transferred at the close of the Fair to an American Museum of Hygiene. The New York City Administration has given assurance that a building will be available and the establishment of a permanent museum of this character in the United States may be confidently predicted.

The Medical and Public Health Building, therefore, will provide a preview of what may be expected to be seen in the American Museum of Health, which has recently been incorporated. It has developed to the point of adequate description.

The subjects have been carefully chosen with their easy visualization in mind and they will be treated with such simplicity that they will be readily understandable to the public. The entire exhibit is being arranged and will be conducted under the supervision and guidance of professional committees of medical and public health experts.

There are three major divisions in the Medical and Public Health Building. They will tell with scientific accuracy, yet with life, color and motion, the story of:

1. What man is—his anthropology, his ethnology, his anatomy and physiology—this in the Hall of Man.
2. The diseases and health hazards which modern man encounters and how medical science attacks and conquers them—this in the Hall of Medical Science.
3. How public health practices prevent disease and protect and promote community health—this in the Hall of Public Health.

There is no place in the Medical and Public Health Building for commercialism. The scheme of financing is as dignified as the project itself. No space as such is available, only the sponsorship of educational and scientific exhibits is sold. Of the sponsors, some are commercial firms of the highest ethical standing, approved by the medical and public health professions. Others are non-commercial groups or individuals actuated only by motives of service to the public. Among those accepted for sponsorship of various exhibits are: New York City Cancer Committee, Cancer; John B. Pierce Foundation, Hygiene of Housing; Eli Lilly & Company, Diabetes, Blood Diseases and Anemias; Cherry Burrell Corporation, Milk Control; Lederle Laboratories, Allergy, Pneumonia, Children's Diseases; Winthrop Chemical Company, Analgesia and Anesthesia; West Disinfecting Company, Occupational Infections and Sanitation; Ciba Pharmaceutical Products, Heart Disease and Endocrinology; Maternity Center Association, Maternal Health; Dorr Company, Water Supply, Sewage Treatment, Waste Disposal; Mrs. Henry Ittleson & Associates, Mental Hygiene; Queensboro Tuberculosis & Health Association, Tuberculosis; American Social Hygiene Association, Venereal Diseases, Gonorrhea and Sex Education; Parke, Davis & Company, Syphilis; American Museum of Health, Inc., Professional Club; Rockefeller Foundation and Rockefeller Institute for Medical Research, Virus Diseases, Infection, and Immunity.

The readers of the *Journal* who carry the banner for public health progress in this country may well keep an eye on the Medical and Public Health Building at the New York World's Fair and thereafter on the first American Museum of Health and lend their aid to the extension of the inherent and underlying

motivation of the whole plan to the end that similar institutions may be established in their own communities for the ultimate objective to which we are all pledged—a healthy and a health-conscious people.

WADE HAMPTON FROST

ONE of the best minds that have adorned the field of public health during this century has passed from us in the untimely death of Wade Hampton Frost.

His promising work in the old Hygienic Laboratory of the Public Health Service, his demonstration of a capacity to link together the data from the field and the laboratory, led to his selection for many notable investigations. These included among others some of the early intensive investigations of typhoid fever, poliomyelitis, especially the 1916 epidemic, the large septic sore throat epidemic in Baltimore, the direction of the Ohio River Stream Pollution Studies, and the Statistical Studies of the Influenza Epidemic of 1918–1919. To each of these he brought the ability to plan for the data he required, their classification and digestion, and, finally, to draw whatever conclusions his logical and critical mind would permit. These latter would be expressed in clear, incisive English that admitted of no misunderstanding.

It was but natural that with these qualities, the Surgeon General should have been requested to assign him as Lecturer on Epidemiology when the new School of Public Health was established at Johns Hopkins in 1919, to become Professor of that subject two years later. As a teacher he was outstanding. From among his students and especially from among those who remained for a time as his assistants will emerge the leaders of public health of the next generation. Indeed, some have already developed. His influence on their habit of thought, in arousing a passion for research and discovery, whatever their field of activity might be, in the development of honest thought and self criticism, cannot help having laid a wide foundation upon which will be built a stronger, straighter public health program for the future.

It was natural that as public health problems multiplied he was sought more and more for his counsel in projected ventures, for his criticism of methods and results, for his advice as to further action. Wherever hard, honest thinking was wanted, "Jack" Frost *wanted* to go. He could not answer all the calls on his time but to whatever he undertook he gave without stint, without thought of reward or public credit. His only requirement was that the work he did should meet his own high standards.

In the American Public Health Association Dr. Frost was a leading figure. Besides having served as chairman of the Laboratory and the Epidemiology Sections of the Association, he was for many years a member of the Governing Council. His independent thinking was many times in evidence in relation to Association policies, and his critical examination of proposed actions will be missed more than many members appreciate. This year he was awarded the Sedgwick Medal for distinguished work in public health. It was never conferred on one more deserving.

From a personal standpoint the following editorial from the *Baltimore Sun*

of May 3 expresses with a beauty beyond the capacity of this writer, the thoughts of those who knew and loved him well:

"One of the fine and rare spirits passed from this earth on Sunday morning in the death of Dr. Wade Hampton Frost. He was a distinguished figure in medical science. To his work his associates will give tribute in due course. But, with all gratitude for his notable professional services, it is of the man himself that those who knew him well will think in the hour of his departure. What they will think will be this: Wherever he stood, there knighthood remained in flower.

"His personality had many facets. He had deep wisdom for the affairs of life, and he had subtle and penetrating wit. He had an austere sense of duty and a fine instinct for leisure. He could be the Spartan and he could be the bon vivant. No matter which facet he turned to life, it shone as in the sun. No one can recall the mean or malicious as his contribution in any relationship. All who knew him recall at this time the thoughts and the acts that were generous and just, high of mind and mood. He made living a noble adventure.

"Those who were privileged to have his friendship find their sorrow embedded in deep thankfulness for his life."

GEORGE MILLER STERNBERG

JUNE 8, 1938, will mark the 100th anniversary of the birth of George Miller Sternberg, President of this Association in 1887. He was born at Hartwick, N. Y. He was graduated in medicine from the College of Physicians and Surgeons, New York, in 1880. At the outbreak of the Civil War, he was commissioned Assistant Surgeon and served with credit through that great conflict. He distinguished himself for courage and repeatedly served his soldiers under fire. At the Battle of Bull Run he was captured by the Confederates, but escaped. It is said that he saw more active service on the battlefield in the Civil War and in the Indian campaigns that followed than any other medical officer of his time.

After the War he went West and experienced the terrible epidemic of cholera at Ft. Harker, Kans., in 1867, from which he lost his wife. In 1873 and 1875 he went through yellow fever outbreaks at Ft. Columbia, New York, New Orleans, and Barrancas, Fla., which unquestionably aroused the interest which he showed throughout his life in this disease, and led to the many studies he made personally as well as to his appointment of commissions to study it. While stationed at Walla Walla, Washington Territory, he began studies on the practical value of disinfectants, work which was subsequently continued in Washington and at Johns Hopkins. In 1885 he was awarded the "Lomb Prize" for his essay on disinfection which was translated into several foreign languages, and went through three editions, the last published in *Public Health Papers and Reports* (Transactions of the A.P.H.A.), Vol. XXV, 1899, p. 624. For many years it was the leading work on disinfection in the English language.

In 1891 he became Lieutenant-Colonel Surgeon and in 1893, Brigadier-General Surgeon General. Under his administration many important advances were made. He was responsible for the creation of the Army Medical School in 1893, which is regarded by some as America's first and oldest school of public health and preventive medicine. On his recommendation, Congress created the Army Nurse Corps and the Army Dental Corps in 1898.

General Sternberg may be called the pioneer bacteriologist of America, accomplishing good work under the most adverse circumstances and with poor equipment. In 1881 he discovered what is now known as the pneumococcus, very soon after the same discovery had been made by Pasteur. Neither suspected the connection of this organism with pneumonia and it remained for Fraenkel, Weichselbaum, and others to clear up the situation. General Sternberg always carried the organism in his sputum and in those days it was known as the organism of sputum septicemia.

There is no doubt that he saw phagocytosis which, however, had been observed by three or four others before him, two of whom, Panum and Roser, advanced fair theories of what it meant, but gave no experimental evidence, and it remained for Metchnikoff to formulate the theory and prove it by experimental work. His first paper was given at the Naturalists' Congress in Odessa in 1883, published in *Arb. a. d. Zool. Inst.*, Wien, 1883.

General Sternberg was a pioneer in photomicrography and some of his pictures remain unsurpassed to this day. While on duty at Fort Mason, Calif., he demonstrated and photographed for the first time in America the tubercle bacillus. In New Orleans, in 1880, he studied malaria and proved that the organism claimed by Klebs and Tomassi-Crudeli as the cause of the disease had nothing to do with it. He was a delegate to the International Sanitary Conference in Rome in 1885, and on his return, demonstrated for the first time in this country the plasmodium of Laveran in the laboratory of Dr. William H. Welch at Johns Hopkins.

His interest in the etiology of yellow fever has been mentioned. His search for the specific organism began in 1879. He twice visited Havana and also Rio de Janeiro, Vera Cruz, and Decatur, Ala., during the severe epidemic of 1888, in his studies. It is claimed by his admirers that he cleared the road for the work of the Walter Reed Commission. He was responsible for the appointment of the Commission headed by Walter Reed, which in 1900 cleared up the etiology of the disease and proved the agency of the *Stegomyia* mosquito, as it was then called, as the carrier.

His writings were voluminous and he gave to America the first comprehensive textbook on bacteriology. His bibliography includes 143 titles on bacteriology, disinfection, infectious diseases, and public health. He was President of the American Medical Association and of the American Public Health Association (1887), and held honorary degrees from the University of Michigan, 1894, and Brown University, 1897.

His later life was spent in Washington, D. C., where he died in 1915 at the age of 77 years. He is buried at Arlington and his monument bears the following epitaph, prepared by Dr. William H. Welch:

Pioneer American Bacteriologist. Distinguished by his studies of the causation and prevention of infectious diseases, by his discovery of the microorganism of pneumonia, and scientific investigations of yellow fever, which paved the way for the experimental demonstration of the mode of transmission of that pestilence. Veteran of three wars, brevetted for bravery in action in the Civil War and the Nez Perces War. Served as Surgeon General of the U. S. Army for a period of nine years, including the Spanish War. Founder of the Army Medical School. Scientist, author, and philanthropist. M.D., LL.D.

NOTE: We are indebted to the Editor of the *Annals of Medical History* for a manuscript prepared by Lt. Col. Edgar Erskine Hume, for assistance in the preparation of this sketch.

SOME PUBLIC HEALTH ASPECTS OF HOUSING

AN issue of the *Journal* which carries a third article on the housing activities of the Memphis Health Department may appropriately call attention to the recognition by housing officials of the contribution made by the public health profession to current housing programs.

The National Association of Housing Officials has referred to "the growing concern of the public health profession with housing conditions and programs of recent months" as "a most encouraging development," and has given effect to this appraisal by distributing the report of the American Public Health Association Committee on the Hygiene of Housing* to all local housing authorities. An equally cordial reception of the public health viewpoint in housing has been shown by the American Federation of Housing Authorities. A statement recently received from Miles R. Frisbie, Executive Director of that Federation, stresses the importance of basic health records in planning a local public housing program, including the necessity for legal powers in the health department for the demolition of insanitary dwellings, and the practical contribution from the health viewpoint to the proper design of new housing projects.

Both of these national housing organizations have recognized the contributions of health departments to local housing programs in cities such as Birmingham, Schenectady, Hartford, and Chicago. Both have paid special tribute to housing activities of the department in Memphis. In that city, housing betterment by the Health Department has ceased to be a negative matter of dealing with scattered sanitary violations and complaints, and has become a matter of constructive "municipal housekeeping" in accordance with a long-range plan.

* *A.J.P.H.*, Mar., 1938.

NEWER KNOWLEDGE OF POLIOMYELITIS

WE are publishing on another page an article on poliomyelitis, bringing the history up to date. It is remarkable to note that with increasing years of study, doubt is taking the place of much we have considered practically proved.

Almost coincidentally is an unusually excellent article on the same subject,¹ which covers much of the same ground. We cannot do better than to quote the conclusions of this article, which in general are in entire agreement with those of the paper read at our annual meeting, and contained in this issue.

It is evident that much of the recent work on poliomyelitis has been destructive rather than constructive in nature—perhaps a healthy sign. At any rate at the present time, we must face the fact that the prospects of solution of the many puzzling problems of this mysterious disease in the immediate future are not bright. Until such a time as the epidemiology is thoroughly understood and until a simple method of determining the susceptibility to the disease has been found and definite specific prophylactic and therapeutic means for combating the disease have been discovered, it would seem that the lay public is entitled to share with us the realization of our profound ignorance of most of the essential facts of the disease. The premature publication of half truths has for years kept the public in a state bordering on hysteria and has thrown a tremendous and increasing onus on the practising physician.

PUBLIC HEALTH EDUCATION*

They Aim to Please in Delaware
—To please and thus to attract and to hold attention, as told by L. C. Messick, director, public health education, Delaware Board of Health, Dover:

The Division of Public Health Education is conducted with the understanding that a project wins understanding allies and multiplies public cooperation with health programs. With this in view, informative releases are sent the newspapers, pamphlets offered to the public, a free quarterly magazine published, talks arranged before pertinent groups, motion pictures and illustrated sound lectures projected before service clubs, granges, P.T.A.s and similar gatherings.

The informative newspaper releases serve as the back-log of the program, tying together the other activities through furthering each and through consistently keeping the reading public acquainted with the work, plans, and accomplishments of the State Board of Health. It has been conservatively estimated that the weekly newspapers use an average of 88.5 per cent of the material sent them, and that the daily papers use 75 per cent.

To carry on this program of newspaper information, regular visits are made to the heads of the various sub-divisions of the State Board of Health, to seek out any newsworthy subjects in their work. When they have any specific plans, drives or projects in need of public attention, detailed programs of suitable publicity are prepared and submitted to them for approval, before being carried into effect. Occasional visits to newspaper editors aid in maintaining their interest and cooperation.

The *Delaware Health News*, published quarterly, is prepared with the belief that it must compete, in homes and offices, with news, fiction, and humor magazines of national distribution. As a result, the format has been entirely modernized, an extra color

used wherever appropriate (and in so far as budgets allow), emphasis given to designing effective front and rear covers, and considerable attention devoted to creating interesting page layouts. The mailing list includes all Delaware physicians, school teachers, ministers, members of the legislature, newspaper and magazine editors, and any others who request that their names be included.

Health exhibits are designed and installed at suitable gatherings, conventions and fairs. Each is so constructed as to make it readily portable and adaptable to almost any display position. In designing exhibits, smart colors, bright lights, and modernistic designs are used to alleviate any atmosphere of gloom and foreboding, and better to attract and hold attention.

Pamphlets and folders on various health subjects are designed for smart appearance, ready reference, and convenient preservation by the public. Pleasing designs and colors are utilized to draw attention, and all publications pertinent to the same subject are prepared on paper of the same color. Internal text arrangements are designed to facilitate rapid reading and ready reference. Included are pamphlets on the various diseases—diphtheria, syphilis, gonorrhea, tuberculosis, diarrhea and enteritis, diseases of children, typhoid fever—and precautions to prevent their contraction or further spread; pamphlets on the selection of menus with regard to economy and nutrition; pamphlets on the care of the teeth; pamphlets on mother and child care and feeding; pamphlets on home, farm, and swimming pool sanitation, and others.

Where suitable, and upon original publication, these booklets and pamphlets are distributed to a part or all of the mailing list; clinics, health centers and libraries are kept supplied with them thereafter, for placing in "free distribution" racks.

Briefly, this section of the State Board of Health endeavors to gain public cooperation and forestall criticism by explaining the motives of the other divisions of the board, and by educating the public in the wisdom of their plans.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Social Hygiene Racketeering—“Hangers on the Social Hygiene Bandwagon” are described in *Bulletin*, Massachusetts Society for Social Hygiene, Little Bldg., Boston, Mass. Jan., 1938.

The widespread publicity concerning the present campaign to stamp out syphilis has called forth an increasing number of scheming promoters who wish to cash in on the national anti-syphilis program and who are setting up here and there “social hygiene organizations” for which they are soliciting funds. We have no quarrel with those whose sincere interest in the subject moves them to set to work and to utilize straightforward, approved and scientific methods in their work.

It must be admitted, however, that there are many men who with an eye to the main chance will climb on any bandwagon provided it is steadily going somewhere and proceed to gather in the shekels for themselves. It is against individuals of that ilk that this warning is directed. The recipient of any appeal for money to help in the campaign to stamp out syphilis will do well to investigate the source of the appeal. . . .

Then is quoted the *Journal of A.M.A.*:

At this time, any new organization in the field of social hygiene should be scrutinized with care, to make sure not only that it is free from racketeering possibilities but also that it has sponsorship which gives reasonable assurance that funds entrusted to it will be expended wisely and in the public interest.

The Health Department Library—We give below a picture of the New York City Department of Health Library. Not many cities will have a real, trained librarian, but the atmosphere and the range of resources may well be duplicated in numerous cities. *What are the characteristics of a desirable, helpful department library? What other characteristics have been noted by the traveling representatives of state or national health agencies?*

This Job of Ours describes the New York City Library:

A library in charge of expert librarians is an advantage very few health departments enjoy. Our library, located in commodious quarters on the second floor, is a branch of New York's Municipal Library. You are welcome to use the library whenever you need it. If you want help in looking up particular subjects, you will find it generously offered. All employees are entitled to the privilege of using the library.

On the shelves are many treasures not easily found elsewhere. Practically all the standard books on public health are there, besides complete reports of the department since its organization in 1867. Among the authors represented are a number of our own, past and present, health department staff members.

Seventy-five periodicals, including 7 from foreign countries, are regularly received. After circulation among staff members who wish to see them in their offices, they are placed on file. Comfortable chairs and pleasing surroundings add to the pleasure of browsing or spending a noon hour there or doing research reading. Books and periodicals may be taken home by arrangement with the librarian.

A new service the library soon hopes to inaugurate is that of supplying recent reprints and pamphlets on subjects of current interest, such as—pneumonia, syphilis, child hygiene, and so on. Selected publications will be collected and kept in stout envelopes according to subject. These “Package Libraries” will be mailed to employees who ask for them on a loan basis. The packages will be kept up-to-date. If this service proves popular, we hope to expand it.

County Nurse Hits the Bull's Eye—County Nurse Gertrude M. Clouse tells about “Publicity in Public Health Nursing” in *State Board of Health Bulletin*, Madison, Wis. Oct.-Dec., 1937.

Miss Clouse has the big idea for effective newspaper publicity (our italics):

The public is so many times swayed by propaganda. Why, then, shouldn't one get the right propaganda before them? That was the way I felt about my newspaper publicity. I wanted so much to get the people public health minded.

Consequently each of my articles was current in subject matter and grew out of a

dire necessity to get that topic before the public at a time when their interest in that topic would be keenest and would do the greatest good.

Do You Know What to Believe?

—Or, do you know what is propaganda, and what is not? Don't ask us what is propaganda, or why we should be able to recognize it. Those two questions must be answered another day.

However, many of our readers and others believe that propaganda is responsible for many questions to be studied with care. And public health educators need to learn how *their* propaganda stacks up with the propaganda from other sources far too numerous even to list.

The Institute for Propaganda Analysis (132 Morningside Drive, New York, N. Y.) has been formed to "help the intelligent citizen detect and analyze propaganda. The Institute

... is a non-profit corporation organized for scientific research in methods used by propagandists in influencing public opinion. It will conduct a continuous survey and analysis of propagandas. By objective and scientific scrutiny of the agencies, techniques, and devices utilized in the formation of public opinion, it will seek to show how to recognize propaganda and appraise it.

The Institute issues a *Monthly Letter* for those who

... desire periodic, objective appraisals of today's propagandas, their sources and the channels through which they flow: newspapers, magazines, radio stations, motion pictures, labor and business groups, patriotic societies, farm organizations, schools, churches, political parties.

The board of directors is made up of university and college professors, including names known to all of us, and two or three others. Some readers will wish that they had broadened the base of responsibility for the project.

Membership is \$2.00 a year, to start Oct., 1937, or later, as one may desire.

At least write for information and samples. If you are interested in propaganda in schools they will tell you about special plans and materials.

Basic to Success Against Cancer
—“Educational Methods and Cancer.” *Bulletin*, American Society for Control of Cancer, 1250 6th Ave., New York, N. Y. Nov., 1937. Develops the following points:

“The first point to bear in mind is the *mental attitude* of the person to be educated . . . Second among the important principles of cancer education is the *complex nature of the process of diagnosis and treatment* . . . A third important point to be remembered is the *nature and degree of complexity of the information to be transferred* . . . Finally comes the question of the *duration of education effort* . . . The enlistment of *hundreds of thousands of individuals who are known, organized, directed and continually aroused is the only way*. The control of cancer requires the establishment and maintenance of a *point of view which must become an integral part of the daily lives of those who would survive.*”

A Comprehensive State Health Education Program—Later in the season we hope to present the plan in detail. This month we quote from the introductory statements in “Kentucky's Plan for Public Health Education,” by Dr. A. T. McCormack and Reba F. Harris, in *Public Health Reports*. Oct. 29, 1937. 5 cents. Supt. of Documents, Washington, D. C.

Since approximately 70 per cent of all public health work has its basis in education, it becomes imperative that more time and thought be given to a well organized plan of public health education. Social Security funds have enabled the Kentucky State Department of Health to set up such a functioning plan.

This plan is based on the point of view that public health is concerned not only with saving lives of human beings, but also with guiding them to learn how to live healthfully and effectively in their daily environments. This guidance becomes more effective with the understanding of the facts that specific health problems arise within certain age

groupings, and that health hazards exist under certain environmental conditions. . . .

Kentucky's new plan of public health education, therefore, is based not upon artificial publicity devices, but upon a better understanding of the health needs of human beings in the various age groupings as they react to each other within the respective environments in which they live. This will be recognized as the ecological approach to public health education.

The first step toward the application of this approach is an efficient corps of public health workers who render all services in an educative way; for, whether it be through emotional appeal or reasoning, the activity or procedure in itself provides the greatest possibility for catching the attention and thereby places the individual or group in a receptive frame of mind for the operation of the learning processes. In other words, a community of both adults and children will understand more readily the values of a safe milk supply if facts concerning its own present supply, and the inherent dangers, are presented for study and discussion at the time the community leaders are planning changes or improvements in such supply. . . .

That the activities and procedures involved in the generalized program of public health in Kentucky may become forces for education in the lives of her people, the Kentucky plan for public health education, coöperatively formulated by all members of the State Department of Health staff, begins with the continued learning, or in-service education, by the two major groups of people who are actively engaged in public health work: namely, (1) The administrative and staff members of the State Department of Health, and (2) personnel of the coöperating county and city health departments.

Through these two major coöordinated groups, the plan extends to the leaders of the organized forces for social betterment and to the public in general within the state and local communities; for it is that group of workers—public health physicians, public health nurses, and sanitary instructors—who are charged with the responsibility of bringing to a greater number of leaders in all phases of social betterment—health, welfare, education, religion, social economics, as well as farm and labor organizations, women's clubs, and bar associations—a better understanding of the values of public health protection.

Then follows "The Functioning Plan" based upon 3 committees and the detailed plans for their direction:

Committee on Continued Learning by State Staffs . . . Committee on Continued Learning by County Unit Personnel . . . Committee on Continued Learning by the Allied Groups.

We have requested a progress report on the first 12 months of experimental work under this plan, to be published in an early summer issue, along with the full outline of the plan.

When You Come to New York—
You will, of course, find most of the national health agencies at 50 W. 50th St., in Rockefeller Center.

Right in the same building is the Museum of Science and Industry, a "must" on the calendar of any one interested in the exhibit form of presentation.

Incidentally, the one best aid to the visitor in Manhattan is the weekly *Cue* (6 E. 39th St.) to be found on news-stands. This will give the maximum of dependable information about plays, pictures, music, dining, and other recreation features.

• **What Life Did—**Says an editorial in *Editor And Publisher*, journal of the newspaper world (April 9, 1938):

A bit ahead of the procession may be *Life* magazine in its picture sequence, published April 11, depicting the birth of a baby. The motion picture upon which the feature is based has run into the opposition of Mrs. Grundy in several cities, and *Life* undertakes more than the normal publishing risk in devoting its central four pages to the story.

Both the film and the *Life* sequence are done with the utmost delicacy, but with the complete eradication of the stork and cabbage leaf fables that used to be fed to the youth of the land. No youngster who gets hold of this copy of *Life* will ever be in any uncertainty as to how he arrived in society, and the way is laid open for diffident parents to reveal what the magazine omits.

Recognition of the dynamite that still inheres in any public treatment of the mystery of generation is seen in *Life's* letter to its 650,000 subscribers. It explains the feature, quotes endorsements from numerous educators, physicians, and editors, and points out

that the four centre pages can easily be removed from the issue if parents don't want their children to learn the facts of life that way.

For our part, and from considerable experience as a parent, we can point to no better channel of education than pictures selected by an editor with a sense of decency, balance, and intelligence. These qualities have not always been evident in picture magazine treatment of similar subjects, some of which have been called to our attention as a father and not as an editor. The temptation to the low-minded is always to tickle the itchy-minded reader, and while you can get circulation that way, you also invite censorship. *Life's* job may not win any new circulation, but it ought not to lose any—and it is certainly no bid for the exercise of blue pencils.

SAFETY

"Death Begins at 40" is the 1938 issue of the highly original annuals issued by Travelers Insurance Co., Hartford, Conn. There are 40 pages of striking text and illustrations against death by careless drivers. The pamphlet is offered for free distribution, and the facts and illustrations may be reprinted. We hope to see some of the material reprinted in many health bulletins. Suggestion: Your reproduction will be more effective if you don't try to copy the red initial letters and the confused typography of some of the pages.

"1938 Accident Facts: Preliminary Edition" contains a wide range of accident facts and figures for 1937. The final and complete edition will be

issued in June. In the meantime the "Preliminary" will be supplied by National Safety Council, 20 N. Wacker Drive, Chicago, Ill. *Free.*

"A Matter of Life and Death," by I. A. Booker. *Journal*, N.E.A., 1201 16th St., N.W., Washington, D. C. Oct., 1937. 25 cents. Safety in education; source material.

"The Nurse Stimulates Employee Interest in Safety," by E. Augustus. *Public Health Nursing*, 50 W. 50th St., New York, N. Y. (date?)

"The Prevention of Home Accidents," J. Melpolder. Includes popular education and group discussion. *Public Health Nursing*, 50 W. 50th St., New York, N. Y. Feb., 1938. 35 cents.

"Safety Education" is a section of "A Guide to the Teaching of Health in the Elementary School." University of State of New York, Albany. Teaching materials; children's activities; references for teachers and for children; sources of inexpensive and free safety materials.

"A Short Story of Organized Recess" describes a plan for securing a safe recess for school children. *Safety Education*, 1 Park Ave., New York, N. Y. Feb., 1938. 10 cents.

"Two Thousand Infants Killed Annually in Accidents." *Statistical Bulletin*, Metropolitan Life Insurance Co., New York, N. Y. Oct., 1937.

BOOKS AND REPORTS

Approved Laboratory Technic—
By John Kolmer and Fred Boener
(2nd ed.). New York: Appleton-Century, 1938. 893 pp. Price, \$8.00.

It is apparent that the original purpose of the manual, to standardize various laboratory examinations and to make clinical pathology increasingly applicable in the diagnosis of disease, is well maintained. The book is the result of the work of 28 collaborators who are the originators of methods themselves.

The manual covers the extensive and ever-widening field of clinical laboratory methods in a clear, complete, accurate, and concise manner. The book has been revised, and enlarged with the addition of many new methods in keeping with the rapid advance of work in this field. References are given for those who are interested in doing further study and collateral reading. Five new chapters have been added: (1) On the methods for hormonal diagnosis of early pregnancy, hydatiform mole, chorion-epithelioma and teratoma of the testicle. Although brief, it covers the essential steps in the laboratory diagnosis of these conditions. Six references are given to original papers. (2) On the laboratory diagnosis of disease produced by yeasts and fungi. This serves as an aid in the usually difficult diagnosis of mycological diseases. Numerous illustrations are included. (3) On the diagnosis of parasites producing disease of the skin and mucous membranes supplemented with illustrations. (4) On methods for conducting tests for allergy. Methods are given for the preparation of allergens and the technic of various skin tests. The technic of the Frei test and the preparation of

the antigen is given. (5) On histological methods and the preparation of museum specimens. This contains much easily readable and useful information on the organization and operation of a laboratory for the microscopic diagnosis of tissues. Many special staining methods are given.

The text is well indexed.

W. D. STOVALL

Experimental Studies of Water Purification—*By H. W. Streeter, Frederick J. Moss, C. T. Wright.* Reprints Nos. 1114, 1170, 1392, 1434, 1565 from *Public Health Reports*. Washington: U. S. Government Printing Office, 1938. 96 pp. Price, \$.25.

Brief Abstract—The six reports included within this binding deal with a series of experimental studies of modern water purification methods which were made over a period of about 6 years in 1924–1929 at the Stream Pollution Investigations Station of the U. S. Public Health Service at Cincinnati, utilizing a large-scale experimental water filtration plant.

The first report contains a description of the experimental plant. The second and third reports deal with results of the first 15 months of operation and with certain relationships between the quality of influent and effluent studied in this connection. In the fourth and fifth reports, results are given of observations on the efficiencies of purification obtained with certain modifications in rapid-sand filtration treatment, such as pH adjustment, increased coagulant dosage, prolonged sedimentation and prechlorination, involving no material changes in the design or construction of existing plants of

the same type. In the sixth and concluding report, the results of the experimental studies are summarized and compared with those of two field surveys of 31 municipal water purification plants, reported in *Public Health Bulletins* 172 and 193.

Two by-products of the studies have been (1) the establishment of a fundamental relationship between the densities of pollution of influent and effluent waters governing all water purification processes observed, and (2) the derivation of some new data bearing on the practical efficiency of various processes of purification and the extent to which this efficiency may be modified by certain physical conditions, some controllable and others non-controllable by the plant operator. The influent-effluent relationships established may be applied to determining limiting degrees of raw water pollution consistent with the production of effluents of any desired quality. H. W. STREETER

Report of Investigations of the Typhoid Fever Epidemic, Minneapolis, 1935—By the Minnesota Department of Health, Minneapolis, Minn., 1938.

In 1935 there was an epidemic of typhoid fever in Minneapolis, Minn., covering 98 days, beginning the first half of May and running until the early part of August. During this time there were more cases of typhoid (175) than had been reported for the previous 6 years.

The *Report of Investigations* has just come to hand. It is well done, thorough, and carries also research work on the comparative resistance of different strains of typhoid and other intestinal bacteria to varying amounts of residual chlorine.

The report is divided into three parts, the first of which gives the epidemiological studies and conclusions as to the source of the epidemic, the second

covers the investigation of the Minneapolis water supply, and the third the research studies mentioned.

The conclusion is reached that of the persons who suffered from typhoid fever, 159 had used water from the Fridley zone in the home, at work, or elsewhere, and that 15 more had used water from the "mixed" zone carrying in part water from the Fridley plant.

In the latter respect this epidemic is not unlike the one which recently visited Croydon, England, in which an otherwise good water supply was infected by one well on which construction work was being done.

The report is well documented and contains a wealth of charts, maps, and figures. Altogether it strikes us as being a very valuable investigation, and unusually well done. It will be of interest chiefly to health officers and to water engineers.

MAZŮCK P. RAVENEL.

Report on Eighth International Congress of Military Medicine and Pharmacy—By Captain William Scamman Bainbridge, M.C.-F., U.S.N.R., Ret., Department of State. Washington, D. C.: Government Printing Office, 1937. 114 pp. Price, \$1.00.

The Eighth International Congress of Military Medicine and Pharmacy met in Brussels, Belgium, June 27–July 3, 1935. The first Congress met in Brussels in 1921, and subsequent meetings were held each second year in Rome, Paris, Warsaw, London, The Hague, Madrid, and Brussels. The Eighth Congress was attended by 10 delegates from the United States of America under the chairmanship of Major Robert U. Patterson, formerly Surgeon General of the United States Army, representing the Army, the Navy, and the U. S. Public Health Service. In all, 39 countries were represented by official delegations composed, in most instances, of medical

officers from the Army and Navy of the respective countries. All the major powers were represented at the Congress.

The *Report* of the Congress deals, for the most part, with certain subjects which were officially reported upon in accordance with the agenda of the Congress. These subjects are:

I. Principles of organization and functioning of medical services in mountain warfare

II. Determination of fitness for the different specialties in armies, navies and air forces

III. The post-traumatic abdomen

IV. A study of the standardization of methods of analysis of food-stuffs for military use

V. Bucco-dental service at the front

VI. Comparative study of the functions of the administrative medical services of armies, navies and air forces

The report as written comprises 111 pages of text. Generally, the material presented is of a highly practical nature and the conclusions reached are those based upon the experience of various medical officers serving in the different armies of the world. The report is of such a nature that it cannot be adequately summarized here, but it should be read by all those interested in military medicine.

G. C. DUNHAM

How To Be a Convincing Talker
—By J. George Frederick. New York: Business Bourse, 1937. 2 vols., 131 pp. Price, \$3.50.

Here we may learn much about talk as a tool—how to get along with people in talk, and how to talk them into doing what we want them to do. There are hundreds of books on public speaking, debate, and related topics. I am not prepared to compare this book with others more or less in the same field, but here we have easy to read working ideas, with numerous illustrative examples, which seem to be usable by many *Journal* readers. It is about talk-

ing, about public speaking, and about listening, too. The application of what is said under "Fallacies about Speeches" and "Care and Responsibility with Speech Material" would change many a convention and meeting program. It is a book to be examined before passing it up. In all of the professions there is increasing recognition of the importance of talk and of public speaking. EVART G. ROUTZAHN

Latent Syphilis and the Autonomic Nervous System—By Griffith Evans (2nd ed.). Baltimore: Wood, 1937. 158 pp., 50 plates. Price, \$3.00.

Noting that the accepted modes of diagnosing syphilis—demonstration of the spirochete, serological tests, and pathognomonic lesions—are not wholly applicable to the diagnosis of latent syphilis, the author pleads for a more detailed analysis of family history and for more frequent recourse to the therapeutic test as supplementary criteria for diagnosis. He then levels suspicion at a train of syndromes attributed to autonomic dysfunction.

Starting from the observation that secondary syphilis entails a generalized lymphadenitis and that the autonomic nerves bear an intimate relationship to the paravertebral lymph chain, the author considers that a definite proportion of diseases of the thyroid, asthma, angioneurotic edema, purpura blanching of extremities, congestion of extremities, and claudication result from syphilis.

The author has not been very critical in his choice from the literature of evidence supporting his hypothesis. He accepts as proven the theory that the spirochete has a granular form and that infection may be congenital in the third generation.

The book will be read with some skepticism by those who have been trained to "deplore a facile assumption of a diagnosis of syphilis." Its chief

merit is that it raises the present rather low level of suspicion with regard to latent syphilis, even though it fails to convince the reader that the suspicion is directed along the proper channels.

RALPH E. WHEELER

Integration, Its Meaning and Application—*By L. Thomas Hopkins and Others. New York: Appleton-Century, 1937. 315 pp. Price, \$2.00.*

This volume represents an exploration of the subject of integration by a committee composed of leaders in the fields of art, biology, philosophy, psychiatry, psychology, and sociology. The first 9 chapters deal with the principles and ideas of integration, while the remaining 5 chapters describe and evaluate practices under various types of school curricula.

Integration is described as a short-hand word used to designate intelligent behavior, the process of integrating referring to continuous, intelligent, interactive adjusting. In the biological field, study of human integration indicates that the human body is the physical stuff from which all of human activities are derived. From the psychological and psychiatric clinic evidence is suggested to show that the personality is so closely bound up together that events which may seem to be far apart in time and quality may nevertheless unite in bringing about a given action. Furthermore, the interaction with society, integration within a culture of an individual influences human characteristics.

Basic conditions are outlined which must be borne in mind in planning a program of education designed to promote the maximum integrating behavior of normal individuals or in reeducating those who are now abnormal. Recently, it is noted, the movement in course of study construction has been away from the subject-curriculum type toward the experience-curriculum type. Since

courses of study affect the experience of pupils and teachers in the classrooms and in life outside the school, the belief is expressed that "These changes must be aiding them to achieve more integrating behavior in all of their interactions with their environment." This book is an interesting reference volume for those engaged in health education.

IRA V. HISCOCK

How To Use Pictorial Statistics—*By Rudolph Modley. New York: Harper, 1937. 186 pp., ill. Price, \$3.00.*

This is a readable book—the result of the writing, the large type on an open page, and the numerous reproductions of examples. The author, a former student of Dr. Neurath, is executive director of Pictorial Statistics, Inc., 142 Lexington Ave., New York, N. Y.

We have had enough bad examples of pictorial statistics to make it important that this book be read by anyone who starts to use the method. No technic can be "learned from a book" without trial and error. But this book should reduce the "error" element.

Happily, the National Tuberculosis Association and a few other groups are making it possible to have in this country fresh examples of the work of Dr. Neurath. However, it cannot be that no others may become practitioners in pictorial presentation, nor that all practitioners should subscribe to the inflexible form laid out by Dr. Neurath. Says Mr. Modley:

Any book which attempts to deal with the method of pictographs must acknowledge its indebtedness to the genius of Otto Neurath. He more than any one man created that method and made it into a significant tool of communication. This makes it more regrettable that Dr. Neurath has not found it possible to follow what seems to me the inevitable trend in the development of pictographs. I hope that the success of our American experiments will convince him that the restrictions he has set up are not fundamental implications of the method.

The crux of our difference of approach lies in our different interpretation of the character of the symbols. Dr. Neurath holds firmly to the belief that pictorial symbols should be international, designed within rigid limitations so that a pictorial Esperanto will be created. He wishes to circumvent a pictorial Tower of Babel and produce at once an international picture language. With that ultimate aim I heartily agree, but I believe his method of achieving it is Utopian.

I believe that pictographs must gradually be accepted as a tool of communication. To achieve this, the symbols must first grope their way into the consciousness of a restricted national audience. They must speak in terms which are comprehensible. Obviously, such symbols must be prepared with their specific audience in mind.

The American and the Chinese farmer dress differently and use different tools; the symbol for "farmer" in America will, therefore, vary from the symbol of "farmer" in China. When national schools will have developed to a point at which they are generally accepted in their countries, then the time will have come to combine the best features of each to create an international picture language.

The book also brings out experimental adaptations of the pictorial method in other directions than the diagram of comparisons: the expression of ideas, the illustration of processes or procedures. Then the use of pictorial material in exhibitions, and in museums receives attention.

Not all of the work of Dr. Neurath or of Mr. Modley is unquestioned. Probably both would more often reach 100 per cent if their tentative layouts were tested on a few people outside their own organizations. Particularly are they liable to add a touch of confusion through the addition of what is likely to seem to be ornament, but which is intended to be explanatory.

"The explanatory pictures serve only to indicate the field to which the symbols apply, or to explain some of the qualifications."

The weakness is that they may neither indicate nor explain. A symbol is not a symbol to another mind until its significance becomes clear. Simple

English words are better than a symbol which slows down the understanding of what follows.

Anyway, we owe much to Dr. Neurath, with his pioneering persistence and his fine sense of color and design, and to Mr. Modley for his effective job of Americanization.

EVART G. ROUTZAHN

Report on the British Health Services—By Health Group of PEP.
London: PEP, 16 Queen Anne's Gate, 1937. Price, \$3.00.

This is a notable book primarily because it represents Great Britain's first attempt to present a comprehensive picture of her health services together with her contemporary problems. In a general manner the organization and functioning of health services is examined and occasional proposals are made for future development of health services. As a rule, however, proposals for future development are vague and indefinite, reflecting perhaps the influence of anonymity with which PEP work is conducted.

No doubt much detailed precise information was used in compiling the report and in arriving at general principles which should govern future improvements. It seems to the reviewer unfortunate, however, that so little precise data were incorporated. Perhaps the material available to those preparing the report accounts for this, as many of the tables presented are not clear. The report points out that prevention of much unfitness can come from a study of social and economic factors, but seemingly fails to appreciate that a study of administrative machinery and of organization can contribute very distinctly to the production of health by bringing about a more effective utilization of health facilities. Only 5 pages are given to a description of the complex administrative machinery surrounding British health services. Resources of

personnel and of money are likewise very incompletely pictured.

First consideration is given to provisions for impersonal protective services and regulation of the environment. Overcrowding and slum conditions have led to State-assisted building programs for elimination of the worst slums. Decentralization of industry is considered one of the most essential moves to offset many of the factors favoring overcrowding and unhealthy environmental conditions. Sanitary facilities—water, sewerage, and scavenger services—are generally adequate in most urban areas but often inflated in costs by the division of suitable areas into several jurisdictions which are not inclined to act as one administrative unit.

Comparatively little development has taken place for the improvement of working conditions in industry. Regulations are often lacking and standards of safety and health if present are very low, with the result that a heavy burden of sickness and accidents occurs. PEP does not offer any concrete proposals which would modify this situation appreciably. Administratively the regulation of industrial health is largely divorced from general health administration.

Trade in food and drugs is for the most part uncontrolled. Laws pertaining to food are administered by local authorities with varying degrees of zeal. Milk-borne epidemics are not infrequent and much control is needed over food composition and quality. A more serious matter is the unrestricted advertising of health foods and drugs, whereby the consumer's health is exploited with exaggerated, misleading, and false claims.

The section on infectious diseases points out that vaccination against smallpox has been compulsory for 60 years but because of loopholes in the law little more than a third of the children are protected. The situation

with reference to diphtheria is so appalling that one cannot avoid questioning the accuracy of the figures presented. According to one of the tables, in 1933 and 1934 there were 59 diphtheria deaths per 1,000 boys, ages 2-5, and 55 diphtheria deaths per 1,000 girls, ages 2-5. It is stated that diphtheria immunization has not found general adoption, and its value is still questioned by some of the profession in Scotland.

Death rates during the first week of life and during the maternity cycle have shown the same resistance to decline found in the United States. Maternal mortality rates are consistently lower in England and Wales, where midwifery is frequently practised, than in Scotland where a greater proportion of births are delivered by physicians. From 5 to about 40 per cent of births occur in hospitals. In addition to the usual provision of clinic centers and health visitors for mothers and children, day nursery schools are operated by a few local authorities. Cash benefits are given mothers who are insured or whose husbands are insured in the National Health Insurance scheme. School health programs are administered by local educational authorities. The nutrition of the working classes, and particularly of mothers and children, constitutes a major health problem since the dietary is quite unsatisfactory. One chapter alone is devoted to nutritional aspects of health and to measures for improving nutritional status. Several concrete proposals are made, one of which is a subsidy to lower the prices of essential foods to make them available to those unable to afford a proper diet. Emphasis is given to the need for a marked expansion of the consumption of liquid milk. To a large extent the nutritional problem has its origin in low income but much of it arises from ignorance of food value on the part of the consumer.

A large section of the report deals with the medical profession and its ancillary workers, with National Health Insurance, hospital and institutional facilities, and special services.

One of the main problems of medical care is to improve the quality of general practitioner services and to extend them to an overwhelming majority of the population. An increasing tendency of patients to choose specialists in preference to general practitioners is ascribed to the poor quality of care frequently given by the latter class of doctor. It is recognized that the general practitioner's decline and the resort of unadvised persons to specialists is symptomatic of the inability of doctors practising general medicine as separate units to meet the standard of care dictated by modern medical needs. Even so, PEP proposals give little reason to expect the situation to improve. Institutional and hospital services are handicapped by overcrowding and inadequacy of organization and equipment. Some correction of this condition it is thought should accompany a strengthening of the position of the family physician who should be able to prevent unnecessary resort to hospitals and to reduce the need for institutional provision. How this strengthening is to be brought about is obscure but presumably is related to opportunities for refreshing the practitioner's knowledge. Refresher courses are arranged by a number of schools and by some divisions of the British Medical Association. Recently the Minister of Health has made plans for refresher courses to insurance practitioners by money grants. Five years must have elapsed since registration and a minimum number of insured patients must be on the practitioner's lists in order to be eligible for a grant. In this connection it appears that the need for refreshing the knowledge of public health personnel has been overlooked.

The shortcomings of National Health Insurance and the arguments against this scheme are discussed. An important defect will be remedied by an expansion to cover dependent family members of insured persons and inclusion of services of specialists. Administration costs constitute an important disadvantage of the insurance principle. In addition there is the objection that a proper overhauling and combining of all medical services is hindered by the scheme. A public medical service organized along with all public health activities supported from general taxes offers lower administrative costs and a more effective service. In spite of this, however, an extension of the health insurance is recommended.

The report, written largely from the authoritative viewpoint in which statements unsupported by quantitative evidence are frequently made, contains nevertheless useful information for the student interested in obtaining a cursory description of the interplay of British services.

PEP will dispel any doubt in the minds of those who feel that conditions of general well-being in the United States are unfavorable in comparison with those of Great Britain. Apparently the British attitude is to "hit upon" rather than to develop measures fostering health. The reviewer cannot escape the feeling that despite Great Britain's more comprehensive statutory provisions for the relief or prevention of ill health, she lags far behind the United States, largely because there has been lacking a dynamic attitude permitting necessary changes to be effected in the social machinery for the better adjustment of forces producing health.

J. O. DEAN

Third Symposium on Silicosis (Saranac Lake)—*Edited by B. E. Kuechle. Wausau, Wis.: Employers'*

Mutual Liability Insurance Co., 1937. 266 pp., paper. Price, \$3.00.

The papers and discussions in connection with this symposium, held at Saranac Lake, N. Y., June 21-25, 1937, are edited, as in the case of the two previous reports, by B. E. Kuechle.

The report comprises the following: Introductory remarks and the significance of the silicotic problem, by Dr. L. U. Gardner (3 pages); etiology of silicosis, by Dr. R. R. Sayers (2 pages), and by Dr. Sayers and Dr. R. R. Jones (19 pages with bibliography); dust concentrations and their measurement, by Prof. Philip Drinker (8 pages); pathology of the pneumoconioses, by Dr. L. U. Gardner (48 pages); physiology of the fibrotic lung, by Prof. W. S. McCann (13 pages); roentgenologic aspects of the normal and silicotic lung, by Dr. E. P. Pendergrass (14 pages); roentgenologic diagnosis of silicosis, by Dr. H. L. Sampson (20 pages); the clinical picture and diagnosis of silicosis with consideration of disability, by Dr. A. R. Riddell (10 pages); control—medical aspects, by Dr. A. R. Riddell (9 pages); control—engineering aspects, by Prof. Philip Drinker (7 pages); administrative aspects of silicosis, by D. E. Cummings (10 pages); and legislative control and compensation, by T. C. Waters (17 pages). Several pages of discussions follow each paper as a rule. A table of contents, a few illustrations, tables and charts, and a brief index complete the volume.

The wide reputation of the various contributors as specialists in their respective fields speaks for the high character of the context, which with careful editing of the discussions renders the volume indispensable to a large group now interested in the pneumoconioses.

As these succeeding annual symposia reports appear it may be seen that American experience is rapidly accumulating on this important subject, while general agreement on many features

is gradually assuming form; yet there are still many problems to be solved, which will come as the result of continued observations and critical studies, particularly upon the chemical, physiological, and infectious nature of the various lung-dust-diseases, and a protracted observation of the progress of cases and methods used to control and prevent them.

There is no doubt a correct feeling among Americans that the question of silicosis and other lung-dust-diseases should be worked out in connection with the characteristics of our own industries and employment methods, since much of the experience from abroad pertains to special conditions such as those occurring in the deep gold mines of South Africa, which do not exist with us. Fortunately many institutions, industries, and individuals are now hard at work upon the problem in the United States and in Canada.

EMERY R. HAYHURST

The Rat and Ratproof Construction of Buildings—By B. E. Holsendorf. Supplement No. 131, Public Health Reports. Washington, D. C.: U. S. Public Health Service, 1937. 68 pp. Price, \$15.

This publication of the Public Health Service designates the rat as "Public Enemy No. 1" among animal pests. The rat, probably equaling in number the human population, destroys property of many kinds, and runs up an individual board bill of about \$2 annually. It bears directly upon public health as the agent disseminating bubonic plague and typhus fever and probably is a factor in transmitting trichina to hogs. The presence of a large rat population is a challenge to the health official but a problem which has not been solved, largely because the public lacks understanding, interest, and willingness to cooperate.

This report summarizes the factors

involved in rat control, discusses the elimination of harborage by proper ratproofing of buildings and other structures, and reviews suppression by other measures. In an excellent series of plates, the structural details of ratproofing are illustrated, together with composite drawings showing how fundamental ratproofing can be accomplished by proper design. A proposed model ordinance requiring the ratproofing of buildings is included as an appendix.

Everyone interested in the rat problem and particularly health and building officials will find this publication a valuable source of information.

J. L. BARRON

Principles and Practice of Bacteriology—By *Arthur H. Bryan, M.A., V.M.D., and Charles Bryan, M.D.* New York: Barnes & Noble, 1938. 267 pp. Price, \$2.25.

The preface and the jacket of this publication leave no doubt as to what the authors think of it. It is a "concise, concrete, and practical reference guide and text for students," including both beginners and practising bacteriologists, and from the wide range of subjects considered these students include medical, dental, dairy, industrial, and agricultural workers. They claim a unique plan of organization which should be of "inestimable value" to users of the book.

The text is very inclusive, covering all fields of bacteriology—all in less than 220 pages of text. "The tables include the pathogenic hyphomycetes and yeasts, primary determinative culture media, plant diseases, soil microbiology, dairy bacteria, veterinary pathogens, human pathogens, dental bacteria, colon typhoid differentiation, and tables of toxins and antitoxins."

The organization of the book strikes us as being good, even if too inclusive. A glossary covers 14 pages. National and State Board Questions in medicine,

veterinary medicine and nursing require 14 pages. It will be seen at once that the treatment of everything is condensed, making the book more of a quiz compend than a text. There are some excellent charts, tables, and pictures.

Conceding the desirability of a book of this type, accuracy is of the first importance. Unfortunately this text contains many errors, many ambiguous statements, many misspellings, and wrong use of words. The English is of the "catch as catch can" type. The first chapter is called History of Bacteriology. We are told that Edwin Klebs "about 1893 isolated the bacteria causing diphtheria" and that Loeffler worked with him in doing this in 1883. At the Wiesbaden Congress (1883) Klebs did not even mention attempts at cultivation or experiments on animals. Klebs saw the diphtheria bacillus but also cocci and believed that there were two types of diphtheria, one due to the cocci and one bacillary. Loeffler, an assistant of Koch—not Klebs—isolated the germ in pure culture (1884) and proved its relationship to the disease. Ehrlich is said to have formulated the humoral theory of immunity. This was due to Buchner. Ehrlich formulated the side-chain theory of immunity. Kitasato is credited with having devised a serum treatment for cholera for which we can find no authority. Sir Ronald Ross is called Hugh, and is credited with having "worked out the plasmodium malariae" whatever this may mean. Noguchi is credited with having discovered the virus of yellow fever, a claim never credited and disproved long ago.

The mistakes in the book are too numerous to mention in detail. A few examples only can be given. On page 126 we find Dorset's egg medium called "media" and two lines below Petroff's medium is properly called. In the same paragraph we find the terms "tuberculous" and "tubercular" both

used to indicate changes due to the tubercle bacillus, though the expression "tubercular milk" for milk from tuberculous cows is entirely incorrect. As forms of tuberculosis, we find "phythis," consumption; "acute miliary (sic) T. B., and scrofula tuberculosis." T. B. means tubercle bacillus, but it is repeatedly used as meaning tuberculosis. There is great confusion in the name of some stains; for example, we find Ziehl-Neelsen's, Zeihl's (sic) acid fast and Ziehl's carbol-fuchsin, all meaning one stain. The names of authors show the same carelessness. We find among books consulted, Zinsser and Bayne-Jones, but later it is reduced to "Zinsser and Jones." An author is entitled to his own name, even if it is hyphenated.

As an example of bad English we find "Antigens (means to form antibodies) are bacteria or their products which stimulate the production. . . ." Page 116, "G. Serological Diagnostic Tests," gives staining of pus, prophylaxis, etc., but no serology. The description of the "Widal or Microscopic Agglutination Tests" on page 203 is too indefinite.

The author acknowledges help and advice from many people, including the President of the Baltimore City College, the Professor of Bacteriology of the Medical School of the University of Maryland, Department of Bacteriology of the University of Alabama, and the Professor of Pathology in the Medical School of the University of Virginia. We wish they had given more advice.

The make-up and printing are good, but the proof reading is poor. We have given perhaps an unnecessary amount

of space to this book, but as it is intended for students, many of whom will probably have no opportunity of going further and obtaining correct information, it seems necessary. We see no excuse for putting a book with so many errors on the market.

MAZÏCK P. RAVENEL

Handbook of Chemistry—By Dr. N. A. Lange (2nd ed.). Sandusky, Ohio: Handbook Publisher, 1938. 1500 pp. with Appendix of 241 pp., by Dr. R. S. Burlington, and Index of 30 pp. Price, \$6.00.

The second edition of this handbook has been brought up to date by revision of 31 tables and addition of 16 new tables as well as other changes.

Naturally a compiler of such a book has difficulty in deciding what data should be included without presenting an unwieldy volume but much of the tabular information desired by the scientist is to be found.

Several tables have been put up in an unusual style. These were found to be even more convenient than the ordinary type table when used. With over 170 tables of chemical, physical constants and a section of 250 pages of mathematical data its value to the scientist can only be appreciated after continued use in the laboratory. It should be a valuable addition to the library of not only the chemist, but physicist, biologist or, in fact, any scientist working in any related field who cannot take the time or who lacks the library facilities to find much of the information herein contained.

CARL S. PEDERSON

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

"See Your Dentist Twice a Year"

—In Detroit, the national health canvass was widened to include questions about visiting the dentist and the dental care received. Less than a quarter of the people canvassed had seen the dentist at any time during the year (excluding visits for extractions), the proportion varying with the economic status of the household from 42 per cent for professional to 16 per cent for unskilled workers.

BRITTEN, R. H. A Study of Dental Care in Detroit, Michigan. *Pub. Health Rep.* 53, 12:446 (Mar. 25), 1938.

Teaching Public Health to Medical Students—As practising physicians over 50 years of age received no teaching in hygiene, it is no wonder that preventive medicine is still considered a "minor." Although important strides have been made in teaching public health in recent years, there are still many more to go before the subject achieves its majority.

FITZGERALD, J. G. Undergraduate Instruction in Preventive Medicine. *J.A.M.A.* 110, 17:1322 (Apr. 23), 1938.

More Pasteurization Problems—

Units which utilize the hot pasteurized milk to pre-heat the incoming cold raw milk (thus partially cooling the pasteurized milk) should keep the hot milk under greater pressure than the cold to avoid possible contamination of the pasteurized milk through mechanical flaws. Measures for insuring this safeguard are described.

FUCHS, A. W. Contamination of Pasteurized Milk by Improper Relative Pressures in Regenerators. *Pub. Health Rep.* 53, 13:496 (Apr. 1), 1938.

How Detroit Provides School Medical Services—Describing the

plan of having school medical work done by practising physicians appointed by the county medical society for 2 year periods, it is recorded that each doctor works one morning a week under supervision. School officials and parents are pleased, and the city is well seeded with young doctors who have had some contact with public health matters.

GUDAKUNST, D. W. The Private Physician in the School. *J. Hyg. & Phys. Educ.* 9, 4:207 (Apr.), 1938.

Some Evidence of Hereditary Tendency to Cancer—Studying mortality records in 10 Massachusetts towns it was found that among the ancestors of persons with cancer the death rate from that disease was over 1 per cent higher than the normal expectancy of cancer deaths. In another study when one parent had cancer, 10.5 per cent of the known children developed the disease, whereas only 8.6 per cent succumbed to it among those whose parents were not cancerous.

LOMBARD, H. L. Studies on the Familial Aspects of Cancer. *New Eng. J. Med.* 218, 17:711 (Apr. 28), 1938.

Better Baby Hospitalization—Public health administrators will be interested in this committee's findings upon the hospitalization of infants. Pointing out that, despite improvement, flaws still exist in isolation procedures and that air-borne infection may be more important than we think, certain promising rules for improving hospitalization of babies are proposed.

McKHANN, C. G., *et al.* Hospital Infections. *Am. J. Dis. Child.* 55, 3:579 (Mar.), 1938.

Ability to Pay for Health—Inadequacies in our public health services are presented in persuasive sta-

tistics. Any one who can maintain his complacency in the face of this factual exhibit deserves some sort of medal.

MOUNTIN, J. W., and O'HARA, H. Differences in Opportunities for Health. *Pub. Health Rep.* 53, 13:485 (Apr. 1), 1938.

The Rickettsioses—If your knowledge of the rickettsioses is hazy, you will find much in this excellent discussion of endemic typhus and Rocky Mountain spotted fevers. The wood tick, the dog tick, and the rabbit tick are all hosts and 5 other ticks may be implicated. Infection acquired by the larvae is passed on to the adult. As it is probable that spotted fever has been endemic in the east and central regions as long as in the west, it is regrettable that it was saddled with the name "Rocky Mountain."

PARKER, R. R. Rocky Mountain Spotted Fever. *J.A.M.A.* 110, 15:1185 (Apr. 9), 1938.

Futility of Contact Exclusion—This British Health Officer holds that, in urban areas, contacts of children suffering from communicable diseases should not be excluded automatically from school.

PAUL, H. Present Practice in Regard to Quarantine and Disinfection. *Pub. Health.* 51, 7:203 (Apr.), 1938.

For All to Read—This dissertation should be required reading for all sanitarians. Not only is it an excellent example of the way a scientific subject may be presented to an intelligent lay audience, but it is filled with useful data about longevity based upon many other factors than tobacco smoking about which so much newspaper publicity appeared.

PEARL, R. The Search for Longevity. *Sci. Month.* May, 1938, p. 462.

Good Family Survey Methods—Can reasonably accurate reports of family health practices be obtained by

house-to-house canvassers sent to gather information from a responsible member of the family? In 3 southern counties the canvass findings were checked by services utilized and the answer was: *in the main, yes.*

PENNEL, E. H., and O'HARA, H. The Validity of Health Service Data Gathered by the Family Survey Method. *Pub. Health Rep.* 53, 12:439 (Mar. 25), 1938.

What Is New in Sewage?—Review of the past year's grist of studies on the chemistry and biology of sewage treatment, sludge digestion, industrial wastes, the various uses of chlorine, and in the field of stream pollution. Of the 65 million United States population served with sewers, the sewage of 25 million is treated to some degree, whereas the remainder is discharged completely untreated into streams, lakes, and the ocean. The sewage load accumulates faster than it is being properly cared for.

PHIELPS, E. B., *et al.* Research in Sewage Chemistry, Sewage Treatment, and Stream Pollution. *Sewage Works J.* 10, 2:173 (Mar.), 1938.

About Pellagra—Something of the history and research on this interesting dietary deficiency disease, together with modern methods of prevention and treatment. Nursing care, which is still of utmost importance despite all the therapeutic advances, is excellently outlined in a companion article by Miss Van Blarcom.

SEBRELL, W. H. Endemic Pellagra. *Am. J. Nurs.* 38, 5:507 (May), 1938.

More about Polio Prevention—When zinc sulphate is used as a prophylactic against poliomyelitis, the way to apply it is to instill it into the nostrils while the head is completely inverted: 0.25 c.c. to 0.5 c.c. is a sufficient quantity.

SHAMINIAN, L., *et al.* Chemo-prophylaxis in Poliomyelitis. *J.A.M.A.* 110, 16:1254 (Apr. 10), 1938.

Visual Health Education—We had an epidemic of health movie dramas about a dozen years ago, but the disease burned itself out to give us a few years of comparative immunity when the health movie fever reached a state of endemicity. We are about to experience a new pandemic of talkies about hygiene, if this movie epidemiologist reads the signs aright.

WEISS, M. Box Office Attraction of Health Movies. Health Officer. 2, 10:504 (Feb.), 1938.

For Complete Community Nursing—After considering the whole field of nursing, public health, institutional, and private duty, the author concludes that a fully coördinated system of nursing in home, industry, and hospital, for rich and poor, including instruction and bedside care, is one of today's vital social problems. It is yet unsolved.

WINSLOW, C.-E. A. Nursing and the Community. Pub. Health Nurs. 30, 4:230 (Apr.), 1938.

ASSOCIATION NEWS

HEALTH CONSERVATION CONTESTS

The Grading Committee charged with the responsibility of selecting the winning and meritorious achievement cities and counties in the 1937 Health Conservation Contests met on April 19.

In the City Contest, the following cities were announced as winners:

In Group I (cities of over 500,000 population) Boston, Mass., wins the first award. Additional awards in this population group go to Cleveland, Ohio, and Pittsburgh, Pa.

In Group II (cities of 250,000 to 500,000 population) Louisville, Ky., and Providence, R. I., receive first awards, and an additional award goes to Dallas, Tex.

In Group III (cities of 100,000 to 250,000) the winner is Hartford, Conn. Awards also go to Grand Rapids, Mich., Yonkers, N. Y., Reading, Pa., Erie, Pa., Honolulu, Hawaii, Lynn, Mass., Tacoma, Wash., and Knoxville, Tenn.

In Group IV (cities of 50,000 to 100,000 population) Sacramento, Calif., gets the first award and other awards go to Evanston, Ill., Newton, Mass., Greensboro, N. C., and Saginaw, Mich.

In Group V (cities of from 20,000 to 50,000 population) Greenwich, Conn., is the winner; and Plainfield, N. J., Auburn, N. Y., Winona, Minn., Elmira, N. Y., Watertown, N. Y., Pittsfield, Mass., Maplewood, N. J., and Orange, N. J., are given awards of merit.

In Group VI (cities of less than 20,000 population) Englewood, N. J., is the winner, and awards go to Hibbing, Minn., Virginia, Minn., and Middletown, N. Y.

In addition to these prizes, Special Awards were given to: Baltimore, Md., Brookline, Mass., Detroit, Mich., Hackensack, N. J., Newark, N. J., New Haven, Conn., Pasadena, Calif., Schenectady, N. Y., and Syracuse, N. Y.

Special prizes were awarded to the cities having the most effective community-wide programs for syphilis control and tuberculosis control. In the Syphilis Control Contest, the first award is given to

Tacoma, Wash., with awards of merit going to Hartford, Conn., Newark, N. J., Louisville, Ky., and New Haven, Conn. In the Tuberculosis Control Contest, the winner is Detroit, Mich., with awards of merit going to Newton, Mass., Hartford, Conn., and New Haven, Conn.

The following counties or district health units were declared winners in the Rural Health Conservation Contest:

In the Northeastern Division, the winner is Columbia County, N. Y., and awards of merit go to Barnstable County, Mass., Saginaw County, Mich., Southern Berkshire District, Mass., Cortland County, N. Y., Mecosta-Osceola Health Unit, Mich., Richland County, Ohio, and Ottawa County, Mich.

In the Eastern Division, the winner is Fayette County, Ky., and awards of merit go to Wicomico County, Md., Washington County, Md., Jefferson County, Ky., Scott County, Ky., Mason County, Ky., Montgomery County, Md., Arlington County, Va., and Kent County, Del.

In the Southeastern Division, the winner is Pike County, Miss., and awards of merit go to Coahoma County, Miss., Lauderdale County, Miss., Pickens County, Ala., and Berkeley County, S. C.

In the North Central Division, the winner is Woodbury County, Iowa, and awards of merit go to Charles Mix County, S. D., Lewis and Clark County, Mont., Union County, S. D., and St. Louis County, Minn.

In the South Central Division, the winner is Amarillo-Potter County, Tex., and awards of merit go to Dallas County, Tex., and Shreveport-Caddo Parish, La.

In the Western Division, the winner is Clallam County, Wash., and awards of merit go to Spokane County, Wash., Yakima County, Wash., and Bannock County, Ida.

Special Awards were given to: Davidson County, Tenn., El Paso County, Tex., and Shawnee County, Kans.

In 1937 for the first time, a Health Con-

servation Contest was conducted in Canada. St. John's-Iberville-Laprairie-Napierville Counties Health Unit, Quebec was declared the winner and other awards were given to: St. Maurice County Health Unit, Quebec, Terrebonne County Health Unit, Quebec, St. James-St. Vital Health District, Manitoba, Kamouraska-L'Islet Health Unit, Quebec, Nicolet County Health Unit, Quebec, and Chateauguay Huntingdon Health Unit, Quebec.

The United States City and Rural Health Conservation Contests awards were presented at the Annual Meeting of the Chamber of Commerce of the United States in Washington, D. C., on May 2. The Canadian Rural Health Conservation Contest awards will be presented during the meeting of the

Canadian Public Health Association in Halifax, Nova Scotia, Canada—June 20 to 22.

The awards for the Syphilis and Tuberculosis Control Contests will be presented to the health officers during the meeting of the American Public Health Association in Kansas City, October 25 to 28.

These contests are conducted annually by the Chamber of Commerce of the United States with the coöperation of the American Public Health Association. The Rural Health Conservation Contest is financed by the W. K. Kellogg Foundation and the City Health Conservation Contest by a group of insurance companies.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

J. Byron Baird, M.D., Health Department, Kingsville, Tex., Director, State Dept. of Health District 5
Charles J. W. Beckwith, M.D., D.P.H., P. O. Box 322, Sydney, N. S., Canada, Divisional Medical Health Officer, Dept. of Public Health
Emmanuel W. Billard, M.D., 33 E. 208 St., New York, N. Y., Physician in charge, Tuberculosis Clinic, Dept. of Health
Marvin A. Childers, Jr., M.D., 820 Alamo National Bank Bldg., San Antonio, Tex., Assistant City Health Officer
James H. Hill, M.D., Box 262, Talladega, Ala., County Health Officer
William B. Hunter, M.D., Lillington, N. C., Harnett County Health Officer
Lynn J. Lull, M.D., Municipal Bldg., La Junta, Colo., Otero County Health Officer
Charles F. Mares, M.D., 605 American National Bank Bldg., Galveston, Tex., County Health Officer
Robert M. Marr, M.D., 92 Elm, Westfield, Mass., Chairman, Board of Health
Harmon U. Sanders, M.D., Federal Bldg., Muskogee, Okla., Senior Physician, Five Tribes Agency
Walter L. Sheppard, M.D., McRae, Ga., Health Commissioner, Telford-Wheeler Counties

Marcus T. Smith, M.D., 541 Davis St., Conway, Ark., Medical Director, District 4
Murray Smith, M.D., Tuskegee, Ala., Macon County Health Officer
John E. Stoddard, M.D., City Hall, Meriden, Conn., Health Officer
Vernon A. Turner, M.D., Richlands, Va., Buchanan, Russell, Tazewell County Health Officer
Harold C. Whims, M.D., Rutherfordton, N. C., Rutherford County Health Unit

Laboratory Section

Elizabeth M. Baethke, 2338 McDowell St., Augusta, Ga., Laboratory Assistant, University of Georgia Medical School
Melba Black, 915 N. Center, Stockton, Calif., Bacteriologist, San Joaquin Local Health District
Rita L. Canessa, Rt. 4, Box 760, Stockton, Calif., Bacteriologist, San Joaquin Local Health District
Leigh H. Churchill, 2114 N. E. Wasco St., Portland, Ore., City Bacteriologist
Hal W. Cutshall, 1630 S. 14 East, Salt Lake City, Utah, Technician, State Board of Health
Michael A. Farrell, Ph.D., 420 Adams Ave., State College, Pa., Associate Professor of Bacteriology, Pennsylvania State College
Fay G. Gardner, 1325 S. 2nd East, Salt Lake

City, Utah, Stenographer, State Board of Health

Sidney E. Gilchrist, 105 S. State St., Salt Lake City, Utah, Chief, Division of Bacteriology, City Health Dept.

Dudley P. Glick, Ph.D., Colorado State College, Fort Collins, Colo., Assistant Professor of Bacteriology

John W. Hornibrook, M.D., National Institute of Health, Washington, D. C., P. A. Surgeon, U. S. Public Health Service

Margaret Ingersoll, 919 First Ave., Salt Lake City, Utah, Laboratory Technician, U.S.V.A.

Wilfrid C. Kennell, 6255 N. E. Willow, Portland, Ore., City Chemist

Thomas L. Martin, Ph.D., 20 E. 9th North, Provo, Utah, City Bacteriologist

Michael G. O'Connor, 47 Mooreland, Springfield, Mass., Chemist, Health Dept.

Edward V. O'Gara, 14th Ave. & Lake St., San Francisco, Calif., Medical Technician, U. S. Public Health Service Laboratory

J. Albert Paradis, Jr., P. O. Box 1809, Juneau, Alaska, Technician, Territorial Dept. of Health Laboratory

Roy E. Rudolph, Jr., 1476 E. 13 South, Salt Lake City, Utah, Bacteriologist, State Board of Health

Ralph B. Williams, 1498 W. 8th South, Salt Lake City, Utah, Bacteriologist, State Board of Health

Winfield F. Wood, 136 State Capitol, Salt Lake City, Utah, Serologist, State Board of Health

Vital Statistics Section

Theodore A. Janssen, 2305 Mt. View Pl., S. E., Washington, D. C., Chief of Nosology Section, Division of Vital Statistics, Bureau of the Census

Public Health Engineering Section

Clifford T. Ayres, Dept. of Public Health, Fort Worth, Tex., City Sanitary Engineer

Carle D. Brown, 388 N. Main, Salt Lake City, Utah, Sanitarian, State Board of Health

Harry L. DeLozier, 311 City Hall, Louisville, Ky., Chief, Division of Milk Control, Health Dept.

William R. Hardy, Box 82, Mineral Wells, Tex., District 2 Sanitary Engineer, State Dept. of Health

Glen J. Hopkins, 211 W. McCarty, Jefferson City, Mo., State Board of Health

Howard M. Hurst, State Capitol, Salt Lake City, Utah, Assistant Sanitary Engineer, State Board of Health

Robert D. Karstaedt, 110 W. School St., Visalia, Calif., Inspector, State Dept. of Public Health

George S. Moore, P. O. Box 125, Albemarle, N. C., Supt., Water & Light Dept.

George W. Newman, Route 1, Yuma, Ariz., Sanitarian, Yuma County Public Health Service

Newell W. Pickett, 2018 S. 6th East, Salt Lake City, Utah, Sanitary Inspector, State Board of Health

Elmer B. Quist, Public Health District 2, Cedar City, Utah, Sanitarian, District 2, State Board of Health

Robert Y. Rhyne, County Health Dept., Wadesboro, N. C., Sanitarian, Anson County Health Dept.

Ellis R. Shields, 266 N. 2nd East, Price, Utah, District Sanitarian, State Board of Health

E. I. Stewart, Jr., 327 E. 1st South St., Salt Lake City, Utah, Sanitarian, State Board of Health

Augustus F. Sweetland, P. O. Box 335, Fort Valley, Ga., District Supervisor, State Dept. of Public Health

Ward Warnock, 207-24 St., Ogden, Utah, Sanitarian, Health District 1, State Board of Health

Food and Nutrition Section

Walter R. Lowry, 903-2nd Ave., Salt Lake City, Utah, Sanitarian, City Board of Health

Charlotte Raymond, 12 Austin St., Newtonville, Mass., Community Nutritionist, City Health Dept., etc.

Alexander A. Singer, 225 E. 79 St., New York, N. Y., Senior Chemist, Dept. of Health

Rafael G. Venegas, D.V.M., Ministerio de Sanidad, Caracas, Venezuela, S. A., Jefe de Abasto de Leche

Oscar Zurer, 993 President St., Brooklyn, N. Y., Health Inspector, Department of Health

Child Hygiene Section

Orren Lloyd-Jones, M.D., Ph.D., 1930 Wilshire Blvd., Los Angeles, Calif., Lecturer in Public Health, University of California at Los Angeles

Chlima Taback, M.D., 1463 Ocean Ave., Brooklyn, N. Y., School Physician, East New York Vocational High School

Marie Wickert, 123 E. 16 Ave., Denver, Colo., Assistant Director, Division of Crippled Children, State Board of Health

Philip W. Woods, D.D.S., Bureau of Health, Augusta, Me., Director, Division of Dental Hygiene

Public Health Education Section

Edgar A. Farrow, M.D., Box 1610, Cedar City, Utah, Supt. and Physician of Pointe Indian Agency, U. S. Indian Service

Bruno Gebhard, M.D., 128 Webster Ave., Manhasset, L. I., N. Y., Exhibit Consultant, Committee on American Museum of Hygiene, A.P.H.A.

Norman F. Gerrie, D.D.S., Rm. 130, State Capitol, Salt Lake City, Utah, Charge of Mobile Dental Unit, State Board of Health

Lyman D. Heacock, D.D.S., 306 State Bldg., San Francisco, Calif., Chief of Dental Service, Bureau of Child Hygiene, State Dept. of Public Health

Bertha K. LaFleur, 3012 Sunnyslope, Miami, Ariz., School Nurse, Globe Public Schools

Elden L. Stewart, 11104 N. E. Wygant St., Portland, Ore., Sanitary and Milk Inspector, Wasco County Health Unit

Florence E. Strause, 309 W. 109 St., New York, N. Y., Supervisor, Highbridge office, Henry St. Visiting Nurse Service

Public Health Nursing Section

Bride L. Cawthon, City Health Dept., Memphis, Tenn., Director, Division of Public Health Nursing

Margaret P. Dietz, Vernal, Utah, Public Health Nurse, State Board of Health

Mary H. Emberton, R.N., 1063 Monroe St., Denver, Colo., Advisory Nurse, Maternal and Child Health, State Dept. of Health

Laura C. Harstad, 816 Oregon Bldg., Portland, Ore., Maternal-Child Health Consultant, State Board of Health

Louella Mahoney, R.N., Salt Lake General Hospital, Salt Lake City, Utah

Marcella M. McInerny, 336 E. S. Temple, Salt Lake City, Utah, State Director of Crippled Children's Service, State Board of Health

Mary McQuillen, R.N., 130 State Capitol Bldg., Salt Lake City, Utah, Supervisor, Staff Education, State Board of Health

Mary C. Robinson, R.N., 961-3rd St., Yuma, Ariz., Supervising Nurse, Yuma County Public Health Service

Belle J. Rosenstock, 141 Hawks Court, Salt Lake City, Utah, Field Nurse, Utah Tuberculosis Assn.

Margrete Skaarup, State Health Dept., Bisnarek, N. D., Supervisor, Public Health Nursing, State Health Dept.

Joy B. Stuart, Ambassador Hotel, Salt Lake City, Utah, Maternal and Child Health Advisory Nurse, State Board of Health

Frances A. Sweeney, R.N., State Teachers College, Flagstaff, Ariz., School Nurse

Bessie Williams, Box 96, Hood River, Ore., County Nurse

Margaret A. S. Willmon, Box 1505, Yuma, Ariz., Nurse, Yuma County Health Service

Epidemiology Section

Louventure Alcindor, M.D., Avenue Cameau, Port-au-Prince, Haiti, Public Health Officer, Port-au-Prince Haitian General Hospital

Leopoldo Briceno-Iragorry, Clinica Luis Razetti, Caracas, Venezuela, S. A., Medico Epidemiologo, Ministerio de Sanidad

Lincoln de Freitas, Filho, C.P.H., National Health Dept., Rio de Janeiro, Brazil, S. A., Health Officer

Paul A. Keeney, M.D., University Club, Harrisburg, Pa., Acting Director, Child Health and Maternal Welfare, and Epidemiologist, State Dept. of Health

Irving Rappaport, 864 Cauldwell Ave., New York, N. Y., Research Assistant in Parasitology, Cornell University Medical College, Dept. of Public Health (volunteer)

Unaffiliated

Eloise B. Cram, Ph.D., National Institute of Health, Washington, D. C., Senior Zoologist

Victor H. Haas, M.D., U. S. Public Health Service Laboratory, San Francisco, Calif., Commissioned Officer

John M. Hayek, M.D., 2319-46 St., Des Moines, Ia., Acting Director, Division of Child Health and Health Education, State Dept. of Health

Joseph R. Horn, D.D.S., 617 W. 168 St., New York, N. Y., Educational work with Oral Hygiene Committee of Greater New York

Catherine F. Ronan, D.M.D., 145 Federal St., Salem, Mass., Dental Supervisor, State Dept. of Public Health

Clement Scott, M.D., 6526 Scotten, Detroit, Mich., Student

John Williams, 10916-100 Ave., Edmonton, Alta., Canada, Health Inspector, Local Board of Health

CLOSING DATE FOR SUBMITTING APPLICATIONS FOR FELLOWSHIP

SEPTEMBER 1 is the latest date the Committee on Eligibility can accept Fellowship applications. This date is set in order that there may be sufficient time to route them through the preliminary steps necessary before they

receive final consideration at the hands of the Governing Council during the Kansas City Annual Meeting. Eligible members who wish to apply for Fellowship are therefore urged to submit their applications in the near future.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Joint Vocational Service, 122 E. 22 Street, New York, N. Y., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS WANTED

HEALTH OFFICERS

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, M.D., Yale; M.S.P.H., Columbia; good clinical background; will consider appointment in child health, epidemiology or public health administration. A350

Physician, aged 38, with excellent training in medicine, pediatrics and epidemiology, is completing work for Dr.P.H., and will consider appointment in administration, preferably in county health work. A366

Physician, M.D., Class A medical school; M.P.H., Harvard School of Public Health; extensive experience in pediatrics and school medical service; also background of county health administration and teaching in medical school, will consider expanded opportunity in teaching or research. A302

Physician, experienced in health administration of cities and states, will consider attractive opening in maternal and child health or health education. A343

Physician, M.D., Class A school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer, seeks full-time administrative position in city or county. A367

Physician, M.D., McGill; C.P.H., Johns Hopkins; excellent background of communicable disease control and school health service, seeks administrative public health position or as epidemiologist. A368

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; now employed, is available for venereal disease control officer. A363

Physician, M.D., Tufts; C.P.H., Johns Hopkins; administrative experience large city health department, will consider position as health officer or epidemiologist. A362

HEALTH EDUCATION

Woman, M.D., Boston University; special work in Columbia and Massachusetts Insti-

tute of Technology; one year's experience in State Hospital; interested in psychiatry, desires position in the east in hospital for mental diseases, or industrial school. H248

Young woman, M.A. in Health Education, Teachers College, Columbia University; with splendid international experience, seeks position as director of health education with preference for New York City. H369

Woman, with excellent preparation and wide experience in health education field; organization, administration, supervision and program making in city, rural and state work. Now employed but would consider good opportunity. \$3,500 minimum. H316

LABORATORY

Experienced bacteriologist with teaching in research background, seeks position as director of laboratory. L370

Bacteriologist and pathologist with wide administrative experience; Ph.D., Brown University, will consider leading position in his field. L371

SANITARY ENGINEERING

Graduate Sanitary Engineer with service under U. S. Public Health Service and state departments of health, especially interested in filtration plant design and operation and shellfish sanitation, seeks employment. E356

Experienced sanitary engineer, graduate of M.I.T., seeks responsible position. E372

CHILD HYGIENE

Experienced physician, M.D. and Ph.D., University of Minnesota; specially qualified in maternal and child hygiene, directing state and local programs; will consider position of better sort. A238

MISCELLANEOUS

Young man, Sc.D., Johns Hopkins; experience in public health and research bacteriology; will consider position in public health work or university teaching. L312

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

NEWS FROM THE FIELD

VENEREAL DISEASE CONTROL BILL PASSES CONGRESS

THE United States Senate, on May 17, passed and sent to the White House the LaFollette-Bullwinkle Bill, providing for a study of venereal disease control measures and the expansion of a program. The measure authorizes appropriations to finance activity by the Public Health Service and coöperation with states to the amount of \$3,000,000 for the fiscal year beginning July 1, 1938, \$5,000,000 the next year and \$7,000,000 the third year, "and thereafter such sums annually as Congress may determine for the purposes of the Act."

The Bill in its final form passed both the House and the Senate by unanimous vote and was sent to the White House with the expectation that it would be signed by the President. The sponsors of the Bill point out that this is not an appropriation and that it will now be necessary to present estimates to the budget director, and ask the appropriating committees of the House and Senate for the inclusion of this item in the Deficiency Appropriation Bill in order to make funds actually available.

STUDY OF MUNICIPAL ABATTOIRS

A STUDY of the cost and operation of 32 city owned abattoirs and the methods employed for the control of private slaughterhouses has been published jointly by the American Municipal Association and the International City Managers' Association, 1313 East 60 Street, Chicago, Ill.

Of the 25 municipal abattoirs in the United States municipally owned and operated for which figures are

presented, 11 are operated by health departments. Construction costs of these plants run from a few thousand dollars to over \$100,000 and the annual operating costs from \$2,800 to \$33,000 some of which is offset by revenues from fees.

WESTERN BRANCH COMMITTEE ON MILK CONTROL

IN order to take advantage of the presence of Robert S. Breed, Ph.D. (Chairman of the Standard Methods Committee on Examination of Dairy and Food Products, Laboratory Section, A.P.H.A.), P. W. Covington, M.D., President of the Western Branch A.P.H.A., has appointed a Committee on Milk Control which will function at the Western Branch annual meeting in Portland, Ore., June 6-8. The personnel of the committee is as follows:

Chairman: Professor Courtland S. Mudge—College of Agriculture, University of California, Davis, Calif.

William Levin, Dr.P.H.—Director of Laboratories, State Department of Health, Portland, Ore.

Austin U. Simpson, M.D.—Director of Laboratories, State Department of Health, Seattle, Wash.

Charles W. Duckworth, D.V.M.—Bureau of Animal Husbandry, Sacramento, Calif.

E. H. Bramhall—Director of Laboratories, State Department of Health, Salt Lake City, Utah.

Dr. Raymond VanBuren Stone—Director of Laboratories, Los Angeles County Department of Health, Los Angeles, Calif.

Lewis H. Howard, M.D.—Health Officer of Pima County, Tucson, Ariz.

OBSTETRICS AND PEDIATRICS COURSES

THE Minnesota State Medical Association, in coöperation with the University of Minnesota Medical School and State Department of Health, began

the second state-wide graduate course in obstetrics and pediatrics in Crookston and Winona, Minn., May 7. The lectures were also given in Hibbing, Willman, Albert Lea, Fergus Falls, Worthington, and Bemidji, Minn.

The Illinois State Department of Health, in coöperation with the educational committee of the State Medical Society, will begin a series of weekly courses on obstetrics and pediatrics on July 5. These will be held at the Research and Educational Hospital, University of Illinois College of Medicine, and will continue through July and August.

SOUTH CAROLINA PUBLIC HEALTH ASSOCIATION MEETING

THE South Carolina Public Health Association held its annual meeting at Myrtle Beach, May 23. New officers of the Association are as follows:

President—W. K. Fishburne, M.D., of Moncks Corner

Vice-President—William B. Furman, M.D., of Pickens

Secretary and Treasurer—Mrs. Frank George, R.N., of Columbia

Representative to the A.P.H.A.—James A. Hayne, M.D., of Columbia

Speakers from outside the state included: Arthur T. McCormack, M.D., President, A.P.H.A.; John A. Ferrell, M.D., Chairman of the Executive Board, A.P.H.A.; Reginald M. Atwater, M.D., Executive Secretary, A.P.H.A.; and Harry J. Mustard, M.D., Biggs Professor of Preventive Medicine, New York University.

PHYSICAL EDUCATION ASSOCIATIONS MERGE

THE forty-third annual convention of the American Association for Health and Physical Education was held in Atlanta, Ga., April 20-23.

The American Association for Health and Physical Education became a de-

partment of the National Education Association in 1936 after a merger of the American Physical Education Association and the Department of School Health and Physical Education of the National Education Association. The new department will be represented by an executive secretary at N.E.A. headquarters, Washington, D. C., after September, 1938, when the association's offices will be moved to that city. The new department will continue the publication of its magazine, *The Journal of Health and Physical Education*.

At the Atlanta convention the association revised its name and will now be known as the American Association for Health, Physical Education and Recreation.

The following officers were elected:

President—Dr. N. P. Neilson, Stanford University, Calif.

President-elect—Margaret Bell, M.D., University of Michigan; Ann Arbor, Mich.

Vice-Presidents—Health Section, Dorothy B. Nyswander, Ph.D., New York, N. Y.; Physical Education, Grover W. Mueller, of Philadelphia, Pa.; Recreation, Frank S. Lloyd, of New York, N. Y.

The association will meet in San Francisco, Calif., in 1939.

NURSING DIRECTOR HONORED

GRACE Ross, R.N., Director of Nursing of the Detroit Department of Health, was elected President of the National Organization for Public Health Nursing at the biennial meeting of that association which was held in Kansas City April 24-29.

Miss Ross came to the department in 1914 and was made Director of Nursing in November, 1915. At that time the nursing personnel numbered 68, and through her efforts qualifications and standards for nursing in the department have been raised to the highest in the country. The nursing staff membership today is 424. It was

stated that the evolution of public health nursing, from a few small technicians of specialized service to a generalized service which covers 70 per cent of the city, may be credited to Miss Ross's determined effort to supply the best possible education for health for the largest number of persons, at the least expense to the community.

MENDEL MEDAL AWARDED DR. PARRAN

THOMAS Parran, M.D., Surgeon General of the U. S. Public Health Service, received in May the Mendel Medal from Villanova College for outstanding work in science. Dr. Parran will be the tenth recipient of the Mendel Medal award founded by the College in 1928 in honor of Gregor Mendel, Abbot of the Augustinian Monastery, Brunn, Austria, who gave to the world the Mendelian Laws of heredity.

PERSONALS

Central States

CLARENCE D. BARRETT, M.D.,* of East Lansing, Mich., Director of the Bureau of Communicable Diseases of the Michigan State Department of Health, has been placed in charge of a newly created full time health unit in Ingham County, with offices at Lansing.

GEORGE D. BLUME, M.D., was recently appointed Health Commissioner of New Boston, Ohio.

FILIP C. FORSBECK, M.D.,* for 6 years Assistant Director of the Bureau of Communicable Diseases of the Michigan State Department of Health, has been appointed Director, succeeding **CLARENCE D. BARRETT, M.D.***

THOMAS E. GIBSON, M.D.,† of Paw Paw, Mich., has been appointed Health Director of Van Buren

County. He was Health Director of Eaton County.

JAMES N. PATTERSON, M.D., formerly Assistant Professor of Pathology, at the University of Cincinnati College of Medicine, has been appointed Director of Laboratories by the Florida State Department of Health. He will succeed the late **PAUL EATON, M.D.†**

Eastern States

RUFUS COLE, M.D., D.Sc.,† Director of the hospital of the Rockefeller Institute, New York, since 1909, received the George M. Kober Medal for distinguished service to medicine from the Association of American Physicians. Dr. Cole's work on pneumonia and the pneumococcus, as well as his efforts in the whole science of bacteriology, was praised by Dr. Frederick F. Russell, of Boston, who made the presentation.

BENJAMIN C. GRUENBERG, PH.D.,* of New York, is a member of the Committee on Biological Science Teaching of the Union of American Biological Societies, which has received a grant from the Carnegie Corporation of New York for the Advancement of Teaching toward support of the educational program.

JAMES J. MINOT, M.D.,† of Boston, Mass., has been elected to the newly created position of Honorary President of the Boston Tuberculosis Association.

MATTHIAS NICOLL, JR., M.D.,* of White Plains, N. Y., Commissioner of Health of the Westchester County Department of Health, retired on April 30, after serving since the organization of the Department in 1930. Dr. Nicoll was formerly State Commissioner of Health of New York. He is succeeded by **GEORGE H. RAMSEY, M.D.,*** recently Assistant Commissioner of the New York State Department of Health.

* Fellow A.P.H.A.

† Member A.P.H.A.

JOHN E. STODDARD, M.D., has been appointed Health Officer of Meriden, Conn., to succeed MICHAEL J. SULLIVAN, M.D.†

DR. WINFIELD E. WIGHT is the new Health Officer of Thomaston, Conn., succeeding DR. JAMES H. KANE, resigned.

Southern States

HAROLD W. BROWN, M.D., Sc.D., Dr.P.H.,† Professor of Preventive Medicine and Public Health at the University of North Carolina, Chapel Hill, N. C., spoke at Duke University, April 14. The subject of the lecture was "Hookworm."

ARTHUR T. McCORMACK, M.D.,* Commissioner of Health of Kentucky, was a guest speaker at the 72nd annual session of the Texas State Medical Association in Galveston, May 10-12. The subject of Dr. McCormack's talk was "Whose Responsibility Is Public Health and Medical Service?"

MEDICAL DIRECTOR GEORGE W. MCCOY,† of the U. S. Public Health Service, Washington, who for the past year has been carrying on field studies on the spread and prevalence of leprosy and the influence of control measures on the disease, will in future have headquarters for these studies and other official duties at New Orleans, La. In addition to his Public Health Service duties, Dr. McCoy is to organize and serve as head of the Department of Preventive Medicine of Louisiana State University Medical School, which Department the University is establishing this year.

WILLIAM J. MURPHY, M.D.,† of Kingsport, Tenn., Assistant Health Officer of Sullivan County, has been appointed to the staff of the Tennessee State Department of Health for work in venereal disease control.

Western States

SAIDIE ORR DUNBAR,* Executive Secretary of the Oregon State Tuberculosis Association, was elected President of the General Federation of Women's Clubs at their meeting in May, in Kansas City, Mo.

DR. MARTHA E. D. RINEHART-ALLEN is the new Health Officer of Fairfax, Calif., succeeding DR. BERNARD J. CONROY.

DR. ALPHONSO O. SKANCKY has been appointed Health Officer of San Bruno, Calif., to succeed the late DR. FRANK HOLMES SMITH.

Puerto Rico

EDUARDO GARRIDO-MORALES, M.D., Dr.P.H.,* Commissioner of Health of Puerto Rico, San Juan, P. R., has recently been acting as Governor of Puerto Rico during the absence of Governor Winship. Dr. Garrido-Morales has been reappointed as Commissioner of Health for 4 years and his appointment was unanimously confirmed by the Senate.

DEATHS

DR. WILLIAM FRANKLIN ELGIN,* associate of the late Dr. Walter Reed, died April 18. He was 76 years old. Long a prominent bacteriologist and formerly a practising physician, Dr. Elgin was a pioneer in the development of vaccines. He specialized in smallpox vaccine production and improved methods of preparation. Dr. Elgin belonged to the American Medical Association, American Public Health Association, American Bacteriological Society, and the Medical and Chirurgical Faculty of Maryland.

ROBERT W. FOWLER, M.D.,† for 42 years connected with public health work in New York, N. Y., died April 28, at the age of 64.

* Fellow A.P.H.A.

† Member A.P.H.A.

PROFESSOR DR. MAX NEISSER, Professor of Hygiene and Bacteriology at Frankfort-am-Main, Germany, died at the age of 69. He was well known for his bacteriologic work on the differential diagnosis of the diphtheria bacillus and on the staphylococcus, and made valuable contributions to knowledge of the mutation of bacilli.

FRANK L. WATKINS, M.D.,* City-County Health Officer of Great Falls, Mont., since 1930, died April 7, of pneumonia, age 58. In 1908 he was appointed to establish the Bureau of Vital Statistics in the State of Ohio, which was regarded as a model in the United States. In 1911 he received the appointment as Special Agent of the Division of Vital Statistics for the government. Prior to 1930, he was associated with the State Health Departments of Minnesota, Mississippi,

and Florida. He was Director of Health Education in the city schools of Tulsa, Okla., for 6 years. He was a member of the A.P.H.A. from 1927 and a Fellow from 1931.

BENJAMIN WHITE, PH.D.,* died April 28, in Southern Pines, N. C., at the age of 59. Dr. White was Director of the Division of Biologic Laboratories, Massachusetts Department of Health, which position he held until his retirement in 1933. Under the sponsorship of the Commonwealth Fund, of which he was a consultant, Dr. White wrote a recent volume entitled *The Biology of the Pneumococcus*. He was an active member of the Massachusetts Public Health Association.

WADE HAMPTON FROST, M.D.,* Professor of Epidemiology in the Johns Hopkins School of Hygiene and Public Health, Baltimore, Md., died on May 1. (See Editorial, page 773.)

* Fellow A.P.H.A.

Investigation of Early Syphilis*

WILLIAM T. CLARK, M.D., AND
CLEALAND A. SARGENT, M.D.

*Associate Professor of Preventive Medicine, University of Buffalo; and
Director, Buffalo Syphilis Control Service, State Department
of Health, Buffalo, N. Y.*

IN May, 1935, the Departments of Health of the City of Buffalo and the State of New York entered into a coöperative arrangement for the development of more effective local measures for the control of syphilis. The program decided upon included as an essential item a field investigation of all early cases coming to the knowledge of the City Health Department through the usual channels of physicians' reports and clinic admissions. The purposes of the investigation were: (1) by tracing backward in time, to discover and bring under treatment the persons from whom infection might have been received; and (2) by forward extension to discover those people who had been infected or exposed to risk by the original patients.

The investigation was concerned chiefly with individuals with whom the patients had been in sexual contact, either prior or subsequent to their own dates of infection; but also included

efforts to reach closely associated non-sexual contacts. When the investigation led to discovery of infected persons, it was extended to include the antecedent and subsequent sexual contacts of such individuals. The chain of infection was followed, both backward and forward as far as possible, but extension beyond the patient's direct contacts was seldom practicable.

This study deals with cases investigated between June 1, 1935, and June 30, 1937. Only cases are included which at the time of admission to clinics, or of report by the attending physician, were satisfactorily identified as early syphilis in the primary, secondary, or early latent stage. All cases were among persons giving histories which placed their dates of infection within the preceding year and who had not been previously reported to the City Department of Health. The 488 cases falling into the above category were designated as "initial" cases. They included 464 cases of genital syphilis and 24 cases of extragenital syphilis. Of the 464 genital cases, 48 per cent were primary, 39 per cent secondary, and 13 per cent early latent.

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

ANTECEDENT CONTACTS

Success in tracing syphilitic infection to its specific source depends on conditions peculiar to venereal diseases. In non-venereal diseases, it may usually be taken for granted that the patient is willing to give information, but he is rarely able to identify a specific source because he himself usually has no way of knowing the exact time and place where the infection was contracted. Again, the patient is by no means the sole, nor even necessarily the most important source of information. Equally pertinent facts may be available from many other informants. In contrast to most other diseases, the circumstances under which genital syphilis is acquired, except among prostitutes and very promiscuous males, can usually be stated quite exactly by the infected person. He is in a position to know with a considerable degree of certainty when infection was contracted and to what particular individual he was exposed. Such information is available from no other source than the patient himself so that the first essential to success in investigation is willingness on the part of the patient to give fully all facts that will aid in identifying the source of infection. Without this coöperation little or no progress can be made.

Since the first and most important factor in successful investigation is the patient's unreserved coöperation, it is desirable to classify patients primarily according to their willingness to give essential information, which is more difficult than at first appears.

It is easy enough to classify those who deny exposure or flatly decline to give information about it, and it is equally simple to designate as coöperative those whose information leads directly to the discovery and identification of infectious syphilitics who verify the account given by the patient, but many histories elicited in a large city are of a different kind. The patient,

with apparent frankness, may give names of persons who cannot be located at the address given or who on investigation are found to be non-syphilitic; or he may profess not to know the names and addresses of the persons with whom contact is admitted. In such cases, it can only be a matter of surmise whether the patient is sincerely coöperating or is purposely giving misleading information.

Among the 464 cases of early acquired genital syphilis there were 33 patients—for the most part, seen only once in the clinic—who were lost from observation before any helpful information had been elicited. The remaining 431 are classified in Table I with respect to their apparent willingness to give information which would lead back to their specific sources of infection.

TABLE I
Success Achieved in Obtaining Information Which Might Lead to the Identification and Examination of Specific Sources of Initial Syphilis Cases—Buffalo, N. Y., 1935-1937

<i>Classification</i>	<i>Number of Initial Cases</i>	<i>Per cent of Investigated Cases</i>
Declined to give information	44	10
Denied antecedent contact	17	4
Apparently willing to coöperate but giving information so indefinite or incorrect that it did not serve to identify persons named	236	55
Willing to coöperate and giving information leading to the identification and location of persons named	134	31
Total	431	100
Lost from observation before investigation was instituted	33	
Total	464	

As shown in Table I, investigation failed in 14 per cent of the cases because of the patient's unwillingness or inability to give essential information. This group (61 cases) includes 10 instances

in which the attending physician declined to give information, and 17 persons who denied having had sexual contact. Ten persons admitted sexual contact but declined to reveal the identity of the persons concerned, and 8 refused to divulge any information. The remaining 16 admitted contact only with their marital partners, who on examination were either non-syphilitic or were infected subsequently and were therefore not the source of infection of the initial case.

It appears at first glance that a larger proportion of the patients were fully coöperative, since the information which they gave led to the identification, location, and interview of the persons specifically named as sources of infection. It is not certain, however, that the figure given has precisely this meaning since only one-half of the antecedent contacts identified were clearly proved to be suffering from syphilis in a presumably infectious stage. In the remaining cases the information given led only to persons who on examination were found to be non-syphilitic or showed evidence of syphilis which was presumably non-infectious. It may be doubted whether the information originally given was complete. If these patients were to be transferred to the uncoöperative group, where they perhaps properly belong, the effect would be to double approximately the number in this class and reduce by one-half the number certainly coöperative.

Between the extremes of definite refusal to coöperate and effective coöperation as verified by the result, is a large class, 55 per cent of all 431 patients, who either professed to be unable to identify their contacts by name and address or gave information which could not be verified by locating the persons named. Of the 47 females included in this group, 20 were public prostitutes and a large part of the remainder might be classed as clandestine prostitutes.

The 189 males were for the most part individuals who named as their sources of infection prostitutes, or women who had been picked up on the streets or in dance halls.

Under the conditions of this study, the principal cause of failure seemed to be the inability of the patients to give definitive information, because of their lack of personal acquaintance with the persons from whom infection was contracted, rather than actual refusal to coöperate. However, it is quite possible that some of those who appeared to coöperate were in fact withholding information. If this were true, more diligent effort might have improved materially the end results. In so far as failure was due to the informant's own lack of knowledge, it is not certain that more persistent effort would have yielded different results.

The antecedent sexual contacts of the 134 cases in which investigation resulted in the location of one or more of the persons specified, numbered 197 individuals, while those of the 236 cases in which contacts were designated but could not be located, numbered 240. In addition, the 236 patients admitted contact with an unknown but considerable number of persons whose names they had not tried to ascertain. Ninety per cent of the contacts of the fully coöperative group were residents of Buffalo as compared with 50 per cent of the 240 contacts designated but not located. Thirty per cent of the contacts in which the investigation was successful were commercial or clandestine prostitutes, as compared with 75 per cent of those in which individuals were named but not located. Forty-nine per cent of the contacts in successful investigations were friends or acquaintances of the initial cases but this was true of only 23 per cent of those in cases when individuals were named but not located. Of the contacts designated and located 21 per cent were

marital partners as compared with 2 per cent of the named contacts who could not be found.

These findings are such as might be expected from the manner in which the two groups of patients were classified. Other factors not susceptible of measurement were in all probability concerned in the success or failure of the investigations of the 464 initial cases.

By investigating the original 464 cases, 66 infectious syphilis cases were discovered among antecedent contacts, that is, contacts with infectious syphilis were found for 14 per cent of the cases. Twenty-six of the initial cases were apparently infected by a marital partner. Excluding cases so infected, 9 per cent of the initial cases had been in contact with infectious cases of syphilis. In other words, assuming generally accepted views as to stages of syphilis in which the disease is transmissible, the source of infection was found for 14 per cent of all cases and for 9 per cent of cases other than those maritally infected.

The coöperation of 134 initial cases was attested by the location of most of their designated contacts. The contacts named by 4 of the 134 patients refused examination. Ninety-four of the remaining 130 patients gave histories of contact with one, and 36 with more than one, person. In the latter group, 16 patients admitted contact with "several" or "many" persons. In designating the probable source of infection of each case, contacts found to have infectious syphilis were chosen in preference to contacts with latent syphilis or apparently non-syphilitic. The status with respect to syphilis, of the 130 contacts selected as probable sources of infection, according to the method described is given in Table II.

The table shows that 51 per cent of the suspected sources of infection were suffering from presumably infectious

syphilis. This proportion, while large, is perhaps less rather than greater than one would expect to find.

TABLE II

*Results of the Examination of Antecedent Sexual Contacts of 130 Coöperative Initial Syphilis Cases, Buffalo, N. Y., 1935-1937 **

Stage of Syphilis of Antecedent Contact at Time of Contact with Initial Case	Number and Per cent of Initial Cases in Antecedent Contact with Persons in Various Stages of Syphilis	
	Number of Cases	Per cent of 130 Cases
Infectious syphilis	66	51
Presumably non-infectious syphilis	32	25
Syphilis, status as to infectivity unknown	17	13
Non-syphilitic	15	11
Total	130	100

* These results do not include all antecedent contacts examined, but only the "most infectious" contact of each initial case. Thus, if a given individual admitted contact with two persons, one of whom was found to have infectious syphilis, and the other to be non-syphilitic, the former person was selected. In other words, results are given in terms of most probable sources of infection.

The 32 patients whose examined contacts were believed to be non-infectious syphilitics include 13 individuals who admitted contact with other persons. These additional contacts could not be found but might have been the true sources of infection. The remaining 19 maintained that the persons identified and examined were their sole contacts. These 19 patients together with the 15 others whose contacts were apparently non-syphilitic are of considerable epidemiological interest. If there were any way of proving that the information they gave was reliable, the possibility of the transmission of syphilis in other than its early infectious stages and by persons without clinical manifestations of the disease would suggest itself.

SUBSEQUENT CONTACTS

The contacts of the 464 initial cases subsequent to date of infection were investigated in exactly the same manner as the antecedent contacts. Excluding the 33 lost from observation, the remaining 431 are classified in Table III according to their apparent willingness to give information as to subsequent contacts.

TABLE III

Success Achieved in Obtaining Information Which Might Lead to the Identification and Examination of Persons Exposed to Infection by Initial Syphilis Cases—Buffalo, N. Y., 1935-1937

	Number of Initial Cases	Per cent of Investigated Cases
Declined to give information	21	5
Denied subsequent contact	280	65
Apparently willing to cooperate but giving information so indefinite or incorrect that it did not serve to identify persons named	48	11
Willing to cooperate and giving information leading to the identification and location of persons named	82	19
Total	431	100
Lost from observation before investigation was instituted	33	
Total	464	

The cases in which subsequent contact was denied was 65 per cent, as compared with 4 per cent with a denial of antecedent contact. Only 11 per

cent of the patients belonged to the class of individuals willing to cooperate but giving unsatisfactory information as to subsequent contacts, whereas 55 per cent of the same patients were in this group with respect to their antecedent contacts. The proportion of patients willing to cooperate and giving identifying and locating data, 19 and 31.0 respectively, were not significantly different for subsequent and antecedent contacts.

The 82 cooperative patients gave histories of sexual contact subsequent to infection with 112 individuals, of whom 60 were marital partners and 52 were extramarital contacts. Of these 112 persons, 92 were located and 90 examined, and 76 were found to have syphilis.

In evaluating these results, consideration must be given to the fact that many subsequent contacts were also contacts prior to the date of the patient's infection. In fact, it was determined that the dates of infection of 21 syphilitic individuals who were both antecedent and subsequent contacts antedated the dates of infection of the initial cases to which they were related. In presenting findings in Table IV as to the status with respect to syphilis of the 90 subsequent contacts examined, account is taken of the 28 individuals examined who were both antecedent and subsequent contacts.

Since the date of infection of each subsequent contact is believed to have been later than that of the initial case,

TABLE IV

Results of Examination of 90 Subsequent Contacts of 82 Cooperative Initial Syphilis Cases—Buffalo, N. Y., 1935-1937

Status of Contact as to Syphilis	Subsequent Contacts	Antecedent and Subsequent Contacts	Total
Infectious syphilis	43	11	54
Presumably non-infectious syphilis	2	7	9
Syphilis, status as to infectivity unknown	10	3	13
Non-syphilitic	7	7	14
Total	62	28	90

it appears that 43 individuals contracted syphilis as the result of exposure to an initial case. Fourteen individuals exposed to the initial case both prior and subsequent to infection were negative upon examination. Hence, of 57 non-infected persons known to have been exposed to early syphilis, 43, or 75 per cent, contracted the disease. This high proportion is of interest in comparison with the proportion of coöperative initial cases for which an antecedent contact with infectious syphilis was found, namely 51 per cent, and indicates failure to discover the actual source of infection in many instances.

CONTACT INVESTIGATION AS A CASE FINDING PROCEDURE

From the health officer's point of view, the object of investigating cases of early syphilis is to discover new infectious cases and to bring such cases under supervision and treatment. The question arises as to whether the case investigations in the present study fulfilled the purposes for which they were intended, and were sufficiently successful to warrant carrying them on permanently.

During the study, 461 contacts were named and 275 located and examined. Of the 275 examined, 233 were sexual contacts and 42 were incidental contacts, for the most part members of the same household as the initial case.

Among the 275 contacts, there were 202 cases of acquired syphilis and 2 of congenital syphilis of whom 55 were themselves initial cases; that is,

although the individual concerned was reported to the Health Department independently, and was accordingly defined as an initial case, investigation revealed that he or she was also a contact of another initial case.

Exclusive of these 55 contacts who were themselves classed as initial cases, there remain 149 syphilis patients brought into the record during the study, 97 of whom were already known to the Health Department, and all such cases had received some sort of treatment. Thirty-four of the 97 cases were delinquent in treatment at the time they entered the study.

Thus, the study resulted in the finding of 52 new syphilis cases, not under treatment or without histories of previous treatment. Of these 45 were among individuals with presumably infectious syphilis.

A larger series is now being collected in Buffalo, not only for the purpose of evaluating case investigation as an administrative procedure but also with the hope of adding to our knowledge of the epidemiology of syphilis. There are many facts regarding the transmission of the disease which remain unknown, and in general these facts are of such a nature that they must be determined by field observations on human beings. The problem as it now presents itself seems to be twofold: (1) reaching a decision as to practicable control methods, and (2) acquiring knowledge as to the essential details of the epidemiology of syphilis.

Nutrition Services in Maternal and Child Health Programs Under the Social Security Act*

MARJORIE M. HESELTINE

Specialist in Nutrition, Children's Bureau, U. S. Department of Labor, Washington, D. C.

THE claim of nutrition to a place in a maternal and child health program rests on two major premises: (1) that good nutrition is essential to optimal development; and (2) that the nutritional status of mothers and children can be improved by educational activities. The relation of nutrition to the growth and development of children is too well established for discussion at this time. The far reaching effects on public health of good nutrition of mothers during the childbearing period has been given vigorous expression by two Scottish writers in a recent notable review of¹ the dietary requirements during pregnancy and lactation. I quote from the summary:

Since the maternal diet in pregnancy and in lactation inevitably affects the well-being of the infant, the health of the whole population depends to a greater or less extent on the feeding and nutrition of the mothers.

In some branches of public health, recognition of the importance of any single health factor leads to direct action as well as to educational activities. Children whose parents cannot arrange with the family physician for immuni-

zation against diphtheria are protected at public health conferences. But children whose parents are not providing adequate food and the other essentials of good nutrition are not protected against undernutrition or malnutrition by the direct action of the health department, except by an occasional sample of cod liver oil or canned or dried milk received at an infant or pre-school conference. The nutrition services carried on by a maternal and child health division are almost entirely educational in nature; education of the families and individuals to make the most of whatever resources they have, and education of public and private agencies in the community to the need for supplementing inadequate resources.

Have we any evidence that education in nutrition results in healthier children? Emboldened by hearing an eminent statistician assert that we do not need to be in doubt about everything that has not been proved to have statistical significance, I venture to say "yes." There have been only a few attempts to study the influence of nutrition teaching but these few give us courage to go on. Doubtless many of you can add from personal experience to the studies that come to my mind: the retardation of dental caries among children attending the nutrition clinic

* Read before a Joint Session of the Food and Nutrition, Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

of the Forsyth Dental Infirmary²; the improvement during 4 of the leanest depression years in the nutritional condition of preschool children examined by pediatricians and dentists on the staff of the Massachusetts Department of Health³; and, still nearer home, the gratifying findings regarding the influence of education on the food purchasing habits of low-income city families studied by the Association for Improving the Condition of the Poor of New York City.⁴

As in other activities for human betterment, much of the pioneering in community nutrition was done by far sighted private agencies. Years before the passage of the Social Security Act, however, a few state departments of public health, either convinced by scientific evidence or acting upon faith, inaugurated nutrition services. The Health Departments of Massachusetts, Connecticut, and New York have maintained such services continuously for more than 10 years. At least 4 other states had employed nutritionists at some time in the past—when federal funds were available for maternity and infancy services or when state legislatures were relatively liberal in making appropriations for public health. It seems safe to say, however, that the principal stimulus to the establishment of nutrition services in maternal and child health programs of public agencies has been through Title V, Part I of the Social Security Act, which authorizes the Secretary of Labor to make grants-in-aid to the states for the extension and improvement of the health of mothers and children, especially in rural areas and in areas suffering from severe economic distress. In advising the Children's Bureau on the administration of maternal and child health services under the Social Security Act, the State and Territorial Health Officers have mentioned the extension of nutrition programs among the public health

activities for which federal funds may be used.

Two of the 3 states that pioneered in the continuous maintenance of nutrition programs have taken advantage of social security funds to add workers to their staffs. Two states that were forced to abandon nutrition programs during the economic doldrums have reinstated the service. Ten states have set up nutrition services in their health departments for the first time. The most recent reports to the Children's Bureau indicated that on September 1, 1937, 15 states were employing a total of 27 nutritionists. In all but one of these the chief nutritionist serves on the staff of the maternal and child health division. In Connecticut the nutritionist heads a division of nutrition and health education. In Massachusetts a supervisor and 7 nutritionists are attached to the maternal and child health division and 2 more nutrition workers, who serve in the division of tuberculosis control, receive technical supervision from the nutrition supervisor. In New York 3 nutritionists serve on the staff of the maternal and child health division and a fourth is assigned by the State Health Department to a project for staff education in a city health department.

The pediatricians or obstetricians who constitute the majority of state directors of maternal and child health have shown interest in and understanding of the contribution of nutritionists to their programs. They have also been quick to realize that nutrition plays a part in other aspects of public health. It is safe to say that no nutritionist has failed to render some service outside the maternal and child health division of the state health department, notably in dental hygiene, public health education, tuberculosis control, and diagnostic clinics for crippled children. When she is assigned to a local health agency, she is, of course, responsible

directly to the local health officer and carries on a general program that includes consulting with the staff and participating in their services to families and individuals.

The question naturally arises why nutritionists have not been employed in all states and territorial possessions that receive federal funds under the maternal and child welfare title of the Social Security Act. The answer is the same as to the question why no two states have submitted identical plans for maternal and child health services. State plans, as formulated by health department officials in consultation with representatives from the Children's Bureau, take into consideration both state needs and state resources. In some states nutrition education in rural areas is already more highly developed than the medical and nursing services given by public health agencies. If a highly organized agricultural extension service and a state department of vocational education are carrying on educational work in nutrition and are reaching the people toward whom the maternal and child health program is also directed, the health department does well to rely upon these resources, at least while it is building up its own organization to the point where it can furnish intelligent guidance to its own nutrition worker and make effective use of her services. Many state plans recognize that nutrition is an integral part of a well rounded program of maternal and child health and make some provision for incorporating effective nutrition teaching in the day-to-day service of the public health nurse and the physician conducting a health conference.

Dr. Morris* has offered convincing evidence from Delaware that a worthwhile nutrition program can be carried

out when two state agencies share in the employment of a well trained nutritionist. Several state health departments that have not been able to appoint a staff nutritionist for the present are using existing resources in the state to help solve outstanding nutritional problems. The serious health situations resulting from the drought of the summer of 1936 led to concerted efforts by health, welfare, and educational agencies in some of the states that suffered most severely. In South Dakota extension service workers, rural rehabilitation home supervisors, home economics teachers, and public health workers have formed a united front in a campaign of education and services to safeguard the health of mothers and children in drought areas. Through the efforts of state workers, nutrition and health councils have been formed in a majority of the counties. Educational material recommended by the state nutrition council as particularly well suited to different teaching situations is being used throughout the state. School lunches are being fostered by community leaders. The belief is widespread that some of the worst consequences of the drought in South Dakota have been averted by the concerted action of the agencies most immediately concerned with food, nutrition, and related health problems.

Although much can be accomplished in promoting good nutrition as a public health measure without drastic change in the personnel of state and local health departments, many state directors of maternal and child health look forward to the eventual appointment of at least one nutritionist as a staff consultant. The regional and special consultants of the Children's Bureau encourage states to appoint one or more nutritionists when the groundwork for a successful program has been laid. Even a single worker in a large state can increase the effectiveness of the

* See Morris, Woodbridge E. Nutrition Program in a State Department of Health. *A.J.P.H.*, June, 1938, p. 718.

nutrition services in the maternal and child health program if sufficient thought is given to the best use of her time and energy.

The activities of the state nutritionists now in service vary considerably in detail, but little in broad general outlines. Perhaps the major responsibility of the staff nutritionist is staff education so that all public health workers who come into direct contact with the public may be in agreement as to fundamentals of nutrition in relation to maternal and child health. The statement is often made that one of the functions of the nutritionist is to keep her public health colleagues informed on what is new in the field of nutrition. Probably a more important function is to keep them informed on what is *still true* in nutrition and on how to teach these generally accepted principles so persuasively and understandingly in terms of everyday food practices that mothers and children form good habits which will withstand the onslaughts of the most uninhibited of food faddists. To aid the effectiveness of nutrition teaching in the home visit, the health conference, the school inspection, the classroom, or the occasional lecture, the nutritionist assembles and evaluates teaching aids, such as bulletins, posters, films, and exhibits. Most workers find it advisable to make full use of all appropriate material from governmental and other reliable sources and to prepare within the state only what is not available elsewhere.

If staff education is the first responsibility of the nutrition consultant, coordination of the nutrition work of allied agencies is a close second. Just as the dental-health consultant interests local dentists in the oral hygiene program of the state department of health, so the nutritionist enlists the interest and support of individuals engaged in educational and service activities related to food and nutrition. The list

of people who can contribute to a public health program in a community may be a long one: the county home demonstration agent and 4-H club leader, the county home supervisor for the rural rehabilitation program, teachers of home economics, welfare workers, school administrators and teachers (including nursery school teachers), school lunch administrators, and others. As a state worker, the department of health nutritionist usually makes her first contact with the state leaders in the fields just listed and by so doing often finds that the way has thereby been paved for good working relationships on a county or community basis.

The extent of direct service that a state nutrition staff can give is perforce strictly limited. When the special maternal and child health demonstration in progress in a state either features or includes nutrition work, the nutrition consultant is often able to give some intensive service within that area. If the demonstration area also serves as a center for the field training of new staff nurses, staff education can be carried on under the realistic conditions of a local health unit. When several nutritionists are employed, participation in child health conferences is often possible on a permanent basis, as a means for training nurses or qualified volunteer workers in the technic of the nutrition consultation. Many nutritionists consider that some work in a local health department and some direct contact with mothers and children is indispensable to meaningful consultation service but recognize that the most far-reaching contribution they can make to a county or community program is through developing local resources for continuing participation in the work of the local unit. One or two inoculations may bring lifelong immunity to specific diseases, but the campaign for good nutrition is a never ending fight

against indigence, ignorance, and inertia.

Length of Life

. . . Again it will have been noted that no advice has been given this evening about how to conduct life so to live long. The reason for this omission is simple. I am not a medical man. It is the proper professional business of medical men to instruct and advise people about healthy and continued living. They have done well at it, and their collective wisdom about it waxes day by day. On the other hand, detached observation suggests that when laymen take on the job, as all too many of them love to do, the results have not been quite universally all that could be desired. Some conspicuous examples could be cited by way of illustration of this point, without having to wander very far geographically. The truth is,

as every physician knows, that human life and living are extremely complicated matters, not amenable to simplification by formula or to amelioration by panacea. Really helpful advice about unravelling these complications will come only from the wisdom that grows out of experience and knowledge. The purity of heart and nobility of purpose of bustling "do-gooders" or the ready omniscience of gentry eminent in branches of science other than medicine are poor surrogates for the real knowledge and wisdom of the seasoned medical practitioner in the search for longevity.—Pearl Raymond. "Lectures to the Laity," New York Academy of Medicine, February 24, 1938, *Sci. Month.* May, 1938.

Accuracy of the Cancer Death Records*

ELEANOR J. MACDONALD, F.A.P.H.A.

Epidemiologist, Division of Adult Hygiene, State Department of Public Health, Boston, Mass.

THE challenge to statisticians to prove that data upon which extensive biometrical methods are used and from which conclusions are drawn are basically accurate enough to warrant this expenditure of effort or to justify the conclusions drawn, suggested the need for appraisal. This study is concerned with the soundness of the data contained in the cancer death records.

The general use of autopsy for exact verification of doubtful diagnoses does not seem imminent. Only about 12 per cent of the cancer deaths at the present time come to autopsy, and these in no sense represent a cross-section of the cancer population. With the limitation in autopsies, the method employed in this study furnishes a reasonable evaluation of the cancer death records.

The late Robert B. Greenough advised checking the accuracy of the information on the cancer death records by interviewing those who were related to or associated with the deceased. The state-wide interest in the cancer program, in effect in Massachusetts since 1926, with the consequent rational attitude toward the disease as an entity, would presuppose a coöperative attitude toward the study. It was an extensive undertaking, financed in part by the Rockefeller Foundation, and coöperated

in enthusiastically in practically every instance by that portion of the population interviewed—approximately 15,000 individuals. Whether, in view of the state cancer-program in operation for the past 10 years, the findings in Massachusetts could be applied to other states is problematical.

The death records were first copied on a special card prepared for the purpose. In addition to the name and address of the individual, the death record contains information concerning the cause of death, date of birth and death, nativity, date of first recognizable symptoms, the operative history, the place of death, any associate cause of death, the record of an autopsy if one were performed, and the name of the individual who signed the certificate.

Comparable information was obtained from the family, every physician employed, hospitals attended, and social workers who knew the case.

There were 6,153 deaths from cancer in Massachusetts in 1932. Since several interviews were required for every completed case record, it was necessary to sample the deaths rather than to attempt to obtain information on every single death for the calendar year. It was predetermined that completed records of one-third of the total deaths should be secured. This necessitated at least one visit to the residences of about one-half of the individuals who had died of cancer in Massachusetts in 1932. The family was visited first in every instance. From this source the

* Read before a Joint Session of the Association of State Registration Executives and the Vital Statistics Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

names of the physicians employed, as well as the hospitals attended, the social workers, and others familiar with the case could usually be obtained. When the family and physicians of one of these cases could not be reached, the case was not followed further. This caused the rejection of approximately 1,000 records after one or more contacts had been made, since records with insufficient data were discarded.

An attempt was made to draw the true picture of the life of the cancer patient from the material thus obtained, and to note differences between this picture and that furnished by the death record itself. While it is realized that in some instances accurate details may not have been obtained, it is believed that in most cases the verified data represent the actual facts.

The sample of cancer deaths surveyed was 32.9 per cent of the total for 1932. That the sample was representative by site of cancer is evidenced by the fact that the distribution in the surveyed population of the several sites studied shows no significant difference by chi-square test from the distribution by site in the total Massachusetts cancer deaths for 1932 (chi-square = 4.9 and $n = 8$). This shows that this sample is representative of the Massachusetts cancer deaths by site for 1932. The geographical fairness of the sample had been assured by having the surveyors collect a certain number of records from each part of the state.

The verified data were in complete agreement with the death records on the question of sex, as was to be expected. Discrepancies as to age were so slight as to be practically negligible. Only an occasional case differed more than a year from the recorded data. Nativity was correct in over 99 per cent of the records. One may assume that the age, sex, and nativity information furnished by the death record is accurate.

The question of operations was reasonably accurate with agreement occurring in 93.7 per cent of all cases. A reasonable accuracy was present in the associate cause of death with agreement occurring in 92.0 per cent of all cases.

The duration of cancer is the least reliable information on the death record. Agreement between the death records and the facts learned in the survey occurred in only 22.8 per cent of the records. This item of information is frequently entirely omitted from the record, and was missing in 53.7 per cent of the cases studied. When the average duration of these cases in which information was available was compared with the verified duration, the true figure was nearly twice as large as that obtained from the death records—13.6 months on the death records and 23.8 months in the survey. From these facts, it is evident that little reliance can be placed on the importance of duration in cancer as determined by the death records.

The most important item from the standpoint of the student of cancer statistics is the value of the record certified as being cancer. The number of cures prevents cancer mortality from being an index of cancer morbidity. With accurate cancer mortality, accurate duration of disease, and a reasonably accurate estimate of the percentage of cures, morbidity can be approximated from mortality data. A death is either certified as being due to cancer or not. The statistician wishes to know how many of those so certified are correct, and how many of those not so certified should have been classified as cancer.

Another problem which is increasing in importance with improved methods of handling statistical data and with better knowledge of the disease is that of the exact primary location of the cancer. The present-day statistician not only wants to know whether or not the patient died of cancer, but also

TABLE I

Comparison of Actual and Death Record Diagnosis

<i>Location of Cancer</i>	<i>Official Death Record Diagnosis</i>	<i>Verified Diagnosis</i>	<i>Complete Agreement</i>	<i>Percentage Agreement with Death Record</i>	<i>Author's Estimate of Percentage Agreement</i>
Buccal Cavity	79	74	66	83.5	84.0

Doubtful—Probably Not Cancer	0	47	0
Non-Cancer	4	37	0
Total	2,033	2,033	1,590	78.2	83.0

where the primary lesion originated. The data obtained in the death record survey furnish an answer to all these questions with the exception of the size of the group classified as dying of other diseases that should have been classified as cancer. Inasmuch as only cancer deaths were verified, additional data were obtained to determine the volume of this particular group.

Table I shows the official diagnosis compared with the verified diagnosis, subdivided by broad types of location of cancer. Four cancer cases were not recorded in the official cancer classification because other diseases which the individual had were given precedence over cancer. While these individuals had cancer, they were classified as follows:

1. Sudden death under ether anesthesia preparatory to operation for extensive carcinoma of the stomach

2. Hypostatic pneumonia following a fracture of the left femur; associate cause, cancer of the prostate gland

3. Shock following fracture of the right hip; associate cause, cancer of the lung

4. Shock due to pathological fracture of right femur and left humerus; metastatic lesions from cancer of the breast

While these cases are classified as dying of accident, they all had extensive cancers, and from the point of view of cancer epidemiology might well have been classified under cancer.

A group of 66 cases was probably malignant, although conclusive evidence was lacking. In most of these cases the diagnosis had been based on observation of clinical symptoms by one or more physicians and although the physician or physicians had not had the advantages of consultation, they had treated the patient over a considerable length of time and did not base their opinions solely on observations of the patients in a moribund condition.

A second group comprising 75 cases was classified as possibly malignant. A physician might state he believed this case to be malignant from the symptoms, but because the patient refused sufficient examination or study of the case, he was not certain. An example of this type of case was the woman who refused examination and whose family refused to permit examination of the body even after death, when all the symptoms pointed toward cancer of

the uterus. Another type of case included in this group of 75 was of those individuals who, although they went to a hospital, refused other than palliative treatment, and whose hospital records read "question of malignancy." A third type of case was of those individuals to whom a physician was summoned only a week or so before death. His opinion had to be based on a superficial examination of a moribund individual.

Forty-seven cases were viewed in which the evidence was presumptive of non-malignancy, but not sufficiently strong to warrant a positive statement. Several of the physicians signing records in this group made the statement that their diagnosis of cancer was only a guess. In other cases the hospital records stated positively that the case was non-malignant, while the local physician was equally positive that it was malignant.

Thirty-seven additional cases were definitely not cancer. Several of them at autopsy were found to be other conditions, and the death certificates were evidently written before the report of the autopsy findings. Others had been biopsied a short time before death with negative findings for malignancy. In one case in which the patient died of heart disease, the physician had written on the certificate that this patient was operated on for cancer of the bladder several years previous to that time and had had no recurrence. The fact that cancer appeared on the death certificate caused this to be certified as a cancer death rather than heart disease. In all of these 37 cases the evidence collected from the family, physician, hospital, and autopsy records seemed sufficiently strong to make the dogmatic statement that none of these cases was cancer.

This analysis of the presence or absence of cancer disregarding location indicates that the presence of cancer

as measured by the death certificate is accurate to somewhere between 89 per cent and 98 per cent. This may be even more closely approximated by the assumption that the probable cancers were cancers, and the probable non-cancers were not cancers. This is a reasonably safe assumption as errors in either of the classifications may well be balanced by the other. This would place the actual figure between 92 per cent and 96 per cent.

An exhaustive analysis of those cases classified as "possible cancer" leads one to believe that approximately three-fourths of the cases were cancer. An estimate that cancer as a disease was accurately diagnosed in 95 per cent of the total cases is felt to be a sound one.

A comparison of the diagnosis of the official death record by broad classification of site of cancer with the verified diagnosis disclosed complete agreement in 78.2 per cent of the total cases. If similar assumptions are made regarding the doubtful cases as were made with total cancer, this figure would be increased to 83 per cent. Frequently, the site of metastasis was given rather than the site of the primary lesion. When these cancers were allocated to the correct site, a decrease was found in the number of cases of cancer of the buccal cavity, of the digestive tract, of the respiratory tract, of the male genitourinary organs, and of the uterus. An increase was apparent in other female genitals, breast, and cancer of other and unspecified organs. Cancer of the skin was practically the same. From Table I the inference is drawn that site of cancer is not particularly well defined on the death record.

This is even more graphically shown in Table II where the broad classifications are subdivided into smaller units. Complete agreement was present in 70.9 per cent of the total cases. If the same assumption as was made above is repeated, this figure may be as high as

TABLE II
Comparison of Actual and Death Record Diagnosis

Location of Cancer	Official Death Record Diagnosis	Complete Agreement	Percentage Agreement with Death Record	Author's Estimate of Percentage Agreement

Total	2,033	1,442	70.9	75.0

75 per cent. The greatest discrepancy appeared in cancer of the liver, biliary passages, and gall-bladder where complete agreement occurred in only 17.5 per cent of the cases. Again, repeating the previous assumption, this figure may be as high as 20 per cent. This is due to the practice, which is still common although far less so than previously, of certifying a death record as being cancer of the liver rather than cancer of the original site.

These findings warrant conservatism in any discussion of cancer by location of organs affected in which mortality figures are used, but are much better than one would be led to believe by reviewing some of the literature.

These figures indicate a more accurate record diagnosis than was shown by Lund and Hoffman¹ in their study from 1918 to 1930. They found 31 per cent of mouth cases recorded as dying of cancer outside the buccal cavity. In

this study 16.5 per cent were found. While this sample of buccal cavity cancer is smaller and subject to more statistical fluctuation, the great difference would indicate that certification in 1932 was far better than the sample of Lund and Hoffman with the median year of death 1921. This points toward an improvement.

A compilation from the literature of 6 studies on autopsies in which the data have been reported so that comparison is possible has been combined in Table III with a review of records from the Massachusetts General Hospital of autopsies performed from January, 1928, to July, 1937, inclusive. This table shows the cases that were clinically diagnosed as cancer, those that were erroneously diagnosed as cancer, and the missed cases that were found only at autopsy. The percentage of erroneously diagnosed cancers varied from 2.2 in Lubarsch's study² to 12.0 in that of Bilz.² The Massachusetts General Hospital figure of 8.4 is in close agreement with 3 of the other studies and is also the median for the series. While attempts are made at the Massachusetts General Hospital to obtain autopsies on as many bodies as possible, the fact that this hospital receives ma-

terial which is difficult to diagnose clinically from all New England, makes its autopsy series a specialized group. Moreover, the cancers by location differ from a cross-section of cancer deaths, and if adjustments were made for these two items alone the rate for erroneously diagnosed cases would not differ greatly from the estimate made from the survey.

This strengthens the belief that 5 per cent erroneously diagnosed cases is close to the correct figure.

The number of missed cases per 100 erroneously diagnosed cases at the Massachusetts General Hospital was 230. In 2 of the other studies this figure was 244 and 264 respectively. The records of the Massachusetts state-aided cancer clinics show 220 originally diagnosed as non-cancer and later changed to cancer, to every 100 first diagnosed as cancer and later changed to non-cancer. Inasmuch as the Massachusetts state-aided cancer clinic cases are followed from first attendance at clinic to death of the patient and are in close agreement with the majority of the autopsy studies, this figure seems suitable to use in estimating the percentage of missed cases. There would thus be between 9 and 18 per cent

TABLE III
Measurement of the Accuracy of Clinical Diagnosis by Autopsy

	Clinically Diagnosed Cancer	Erroneously Diagnosed (Clinically Diagnosed Cancer— Found to be Non-cancer at Autopsy)	Missed Cases (Clinically Diagnosed Non-cancer— Found to be Cancer at Autopsy)	Percentage of Erroneously Diagnosed Cancer	Missed Cases per 100 Erroneously Diagnosed Cancer
Wells ²	400	33	178	8.2	539
Lubarsch ²	7,426	163	1,312	2.2	505

de Vries ²	1,102	102	249	6.5	244
Current Study—Massachusetts General Hospital	677	57	151	8.4	230

missed cases, the most probable figure being 11 per cent.

The total error in the number of cancer cases reported would be about 6 per cent (11 per cent missed cases minus the 5 per cent erroneously diagnosed cases). If 6 per cent were added to the number of recorded deaths in Massachusetts, a figure would be obtained which would closely approximate the actual cancer mortality.

The analysis of these data indicates that in Massachusetts identification of cancer deaths is sufficiently accurate to warrant statistical compilations on age,

sex, nativity, and the disease as a whole. There is a considerable error in exact location of cancer and a large error in duration of disease, and the statistician should not draw conclusions on these data without making corrections for errors known to exist.

Tobacco, Alcohol, and Longevity

. . . The net result is obvious. In this group of nearly 7,000 men the smoking of tobacco was associated definitely with an impairment of life duration, and the amount or degree of this impairment increased as the habitual amount of smoking increased. The contrast between the life tables relative to the implied effects upon longevity of moderate smoking, on the one hand, and the moderate use of alcoholic beverages, on the other hand, is very striking. The moderate smokers in this material are definitely shorter lived than the total abstainers from tobacco; the moderate drinkers are not significantly

worse or better off in respect of longevity than the total abstainers from alcohol.

Heavy indulgence in either tobacco or alcohol is associated with a very poor life table, but the life table for heavy smokers is definitely worse than that for heavy drinkers up to about age 60. Thereafter to the end of the life span the heavy smokers do a relatively better job of surviving than the heavy drinkers. But neither group has anything to boast about in the matter of longevity.—The Search for Longevity, by Prof. Raymond Pearl, *Sci. Month.*, May, 1938, p. 480.

Precision Methods in the Determination of the Heavy Metals*

LAWRENCE T. FAIRHALL, PH.D.

*Principal Industrial Toxicologist, U. S. Public Health Service,
Washington, D. C.*

A CERTAIN amount of the chemical work in industrial hygiene requires only routine procedure of the conventional type—such as the determination of the amount of a given constituent in air samples, the analysis of factory products, or of raw materials, the analysis of rafter dusts or of water samples. Such work requires only ordinary care and average skill to yield perfectly satisfactory results. Furthermore, a routine procedure is usually quite sufficient for the accuracy desired or necessary.

There are phases of investigation in industrial hygiene, however, that require the highest type of chemical skill, yet it appears to be quite generally the case to relegate such work to a routine analyst. It is obvious that an investigation, no matter how ambitiously projected, is no better than the physical data collected, or the analytical figures upon which it is based. A special plea is therefore made, not necessarily for simpler, but for more precise methods and for more careful evaluation of the results obtained. This may entail more work, time, and expense than an investigation would appear to warrant; but it is a question whether such a rapidly increasing field

as industrial hygiene would not be better served eventually. A poor job is not only a poor job—it multiplies the later work of others in the same field.

One of the major undertakings yet to be done in industrial hygiene is the question of methods of analysis. In spite of all the work that has been accomplished, this will be true for some time to come. Just as the great advances in biochemistry have been conditioned and fostered by more and more exacting methods of analysis, the ground work and basis of industrial hygiene is that of its analytical data.

In a sense this is uninteresting work. As in analytical chemistry in general, nothing basically new is added in working out a method of analysis. Rather it consists in adaptation of recognized methods to a specific or unique problem. Occasionally a conventional procedure is discarded entirely and a breath-taking short-cut substituted, as shown in analytical spectrography, but even here its validity must be based on recognized procedure of the highest order.

I propose to confine myself to selected phases of analytical procedure, rather than to a detailed discussion of analytical methods. The methods of analysis are constantly changing to meet new or unforeseen conditions, and this shows a healthy and fortunate tendency. There are two directions in

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

which these changes occur: one in the direction of simplification and rapidity; the other toward greater accuracy. The former meets the pressure of routine output; the latter may need some explanation—but no justification surely. The higher degree of accuracy is needed more in specialized investigations of industrial toxicology. It is with the latter that I propose to deal here and to discuss certain phases of the analytical problems with which we recently have been concerned.

We no longer have the massive exposure to injurious substances that was true only a few years ago in industry. Great improvements have been made in preventive control. Therefore the problems of occupational disease are more difficult because the actual degree of exposure is smaller—smaller amounts of poisonous materials are involved—and the clinical pictures of various intoxications are modified in similar fashion. For instance, lead is still the ranking industrial poison, yet control measures are so good that the degree of exposure of workers in a modern factory is very low and the actual number of cases of typical lead poisoning is steadily diminishing.

With respect to the heavy metals, investigations in industrial hygiene are concerned with quantities that are very small. Unfortunately these very small amounts are concealed in quantities of biological material which are enormously large in proportion. Thus, a significant amount of a metal in a day's output of urine of 1,500 c.c. may be 30 or 40 micrograms. This represents a concentration of 3 or 4 parts in 150,000,000. Furthermore, organic material notoriously interferes with the chemical determination of the heavy metals and must be removed. In the determination of the total arsenic content of a human liver, say, this becomes a very difficult problem. Therefore I would like to discuss two things that betray more than

anything else the difficulties of such analytical procedure.

DRY ASHING PROCEDURE

It is well known that one of the most troublesome operations in the determination of the tissue or excreta content of the heavy metals is that of ashing. At the same time, nothing can contribute so much to lack of precision as the process of removal of organic material. In spite of this, however, the amount of attention that has been directed to this problem is out of proportion to its importance. With such metals as arsenic, cadmium, antimony, and mercury, dry ashing is of course out of the question. However, in certain cases dry ashing is exceedingly useful if it can be safely employed, although it requires great care and patience to carry out properly. The extraction of the ash must not only be thorough, but one must not overlook the possibility of the formation of insoluble phosphates or silicates at the temperatures employed. This means that *all* residual material—commonly supposed to be "silica"—must be carefully dissolved and added to the acid extract. Unless this is carefully attended to, the resulting analysis may be tremendously in error.

From time to time the possibility of loss in ashing as a result of using too great a temperature is pointed out. However, very little work has been reported with respect to losses in ashing at various temperatures.

In a recent study made with respect to lead losses in ashing we found that the nature of the compound is of some importance. Owing to the predominance of chlorides in tissues or excreta there is the possibility of formation of lead chloride which is rather volatile compared with other lead salts. Known amounts of lead as chloride were heated in platinum dishes for similar lengths of time in an electric muffle

furnace in which the temperatures could be measured by means of a carefully calibrated pyrometer. The lead could be quantitatively recovered in those cases in which the temperature never exceeded 500°C . At 600°C . losses began to be evident and at 750°C . they were serious, amounting to some 40 per cent. With lead phosphate, however, losses did not begin to occur until a temperature of 750°C . had been reached and even at 850°C . amounted to only a few per cent. These experimental data are shown graphically in Figure I in which the lead recoveries are plotted together with the vapor pressures of lead chloride.¹ In addition to the chloride and phosphate alone, lead carbonate alone, and chopped meat to which lead chloride had been added, were ashed at temperatures intermediate between those in which losses occur with the chloride and phosphate—with no evidence of loss of lead. It is evident, therefore, that so far as lead is concerned, an

ashing temperature of 500°C . is perfectly safe.

WET ASHING PROCEDURE

While dry ashing is exceedingly useful for several of the heavy metals, it is frequently slow and time consuming and requires more or less constant attention. It is particularly difficult to ash any quantity of blood or liver because these substances tend to form a tarry mass on charring that swells or puffs up into a mass of spongy carbon several times the volume of the original substance. Because of this and because of possible loss with several of the more volatile heavy metals, we have attempted to find a more nearly universal method of ashing that would satisfy exacting requirements.

A study was made of the usual oxidizing materials—nitric, perchloric, permanganic, and sulphuric acids, chlorine, nitrosyl sulphuric acid, and hydrogen peroxide.

There are objectionable features to

FIGURE I

this study 16.5 per cent were found. While this sample of buccal cavity cancer is smaller and subject to more statistical fluctuation, the great difference would indicate that certification in 1932 was far better than the sample of Lund and Hoffman with the median year of death 1921. This points toward an improvement.

A compilation from the literature of 6 studies on autopsies in which the data have been reported so that comparison is possible has been combined in Table III with a review of records from the Massachusetts General Hospital of autopsies performed from January, 1928, to July, 1937, inclusive. This table shows the cases that were clinically diagnosed as cancer, those that were erroneously diagnosed as cancer, and the missed cases that were found only at autopsy. The percentage of erroneously diagnosed cancers varied from 2.2 in Lubarsch's study² to 12.0 in that of Bilz.² The Massachusetts General Hospital figure of 8.4 is in close agreement with 3 of the other studies and is also the median for the series. While attempts are made at the Massachusetts General Hospital to obtain autopsies on as many bodies as possible, the fact that this hospital receives ma-

terial which is difficult to diagnose clinically from all New England, makes its autopsy series a specialized group. Moreover, the cancers by location differ from a cross-section of cancer deaths, and if adjustments were made for these two items alone the rate for erroneously diagnosed cases would not differ greatly from the estimate made from the survey. This strengthens the belief that 5 per cent erroneously diagnosed cases is close to the correct figure.

The number of missed cases per 100 erroneously diagnosed cases at the Massachusetts General Hospital was 230. In 2 of the other studies this figure was 244 and 264 respectively. The records of the Massachusetts state-aided cancer clinics show 220 originally diagnosed as non-cancer and later changed to cancer, to every 100 first diagnosed as cancer and later changed to non-cancer. Inasmuch as the Massachusetts state-aided cancer clinic cases are followed from first attendance at clinic to death of the patient and are in close agreement with the majority of the autopsy studies, this figure seems suitable to use in estimating the percentage of missed cases. There would thus be between 9 and 18 per cent

necessary to yield a satisfactory white ash.

THE DIPHENYLTHIOCARBAZONE

METHOD FOR LEAD

The precise evaluation of certain of the metals, notably lead, has benefitted greatly within the past few years by the colorimetric diphenylthiocarbazone (dithizone) method of Fischer³ which is extremely sensitive. Useful as it is, it is not specific for lead unfortunately, as a number of other metals give practically identical colors. One must realize, therefore, that in determining lead in a given substance the appearance of the usual cherry color is not necessarily indicative of lead even after the addition of cyanide, and must take account of the possibility of the presence of other metals giving similar colors. Care should be used with respect to the quantity of cyanide used, as it tends to diminish the apparent amount of lead present.

In spite of these difficulties—which are not at all insurmountable—the diphenylthiocarbazone method is extremely valuable for the determination of lead in a great many cases. It is particularly useful for the determination of lead in spray residue on fruit and as developed by Clifford and Wichmann⁴ seems ideal for that purpose. Here the ratio of lead to other metals, or to the total amount of ash itself, is relatively great compared with similar ratios in tissues or excreta.

It would appear that where the diphenylthiocarbazone method has been applied to the examination of excreta for lead, insufficient account has been taken of the other metal constituents. Zinc and tin are normally excreted in far greater amount than lead and unless careful account is taken of the tin in particular, this may well be accounted as lead. Furthermore, Vinson⁵ has recently reported that zinc in the presence of cyanide is definitely an in-

terfering substance in the determination of lead by the diphenylthiocarbazone method.

When it is recalled that the urinary excretion of zinc is in the neighborhood of 1 milligram per day and that of tin at least as much, the determination of a few micrograms of lead in the presence of these substances in urine is obviously a more difficult problem than the determination of relatively much greater amounts of lead in simpler material.

APPLICATION OF SPECTROGRAPHIC METHODS

Recent years have witnessed a pronounced popularization of the spectrograph for analytical purposes and its immense advantages in metallurgical work perhaps more than anything else have drawn many to employ it for determination of the metals in biological materials.

At present no single method apparently is so full of promise for the analytical evaluation of traces of the heavy metals as the spectrographic. Its extreme sensitivity and the ease with which material may be examined, as well as the minute amounts of material needed for examination, are all most attractive features, and it is not surprising therefore that it has been so widely heralded.

It is unfortunate for its use in this field that some accounts of its application to the determination of traces of metals in biological material have been so enthusiastic. In reality there are formidable difficulties that stand in the way of its use for the precise evaluation of these traces of metals in tissues and excreta.

Familiarity with spectrographic procedure leads one to feel that there is no question that careful search for and comprehension of these difficulties of analytical application will lead to their elimination and yield a precise method of the greatest utility. However, the

rapid advance in the use of the spectrograph for the quantitative determination of metals in biological substances has been in the direction of extending its application, rather than in the narrower (and more uninteresting) field of tracing its difficulties of application.

The mechanical difficulties of quantitative spectrography—whether with reference to the production of the spectrogram, or to the measurement of line intensity—can obviously be met and satisfactorily eliminated as a result of care and experience. The difficulties to which I particularly refer are those of quantitative interpretation and the latter are not so dependent upon measurement of line intensity; whether by the “internal standard” method or by its photometric refinement, the rotating logarithmic sector method, as upon conditions prevailing within the arc and upon other substances present with the metal sought. While the latter condition is of no great significance so far as qualitative spectrography is concerned, it is very important in its quantitative application. The line intensity for a given arc and exposure is not constant during the whole time of arcing, but depends upon the relative rate of distillation of its constituents. Thus, the time required for the line spectra of an element to appear and the length of time it will remain after starting the arc depend upon how quickly it volatilizes. Bauer⁶ found in the determination of lanthanum in the presence of large amounts of calcium that the lanthanum spectrum reached its full intensity at the end of 2 minutes after most of the calcium had already volatilized.

Aside from quantitative variation in the spectrum with time, it is very important to know exactly what part of the arc is focused upon. Mannkopff and Peters⁷ found that such elements as lead, silicon, bismuth, tin, and

others show a line intensity in the cathode layer frequently as much as 100 times that in the gas column of the arc. Certain lines may be very intense near the cathode and yet vanish completely in the arc column.

It is particularly important with respect to biological material to recall that the type of lines emitted and their intensities are affected by the presence of an easily ionizable substance, such as sodium chloride, in the arc.

This makes more or less imperative the use of a medium similar in composition to that of the substance under test, but of course spectrographically free from traces of the metal being evaluated—not at all an easy task.

Webb^{8,9} and also Willey¹⁰ have pointed out that in the graphite electrode impurities, the strongest lines of which can only be faintly discerned in the “blank” spectrum, may leap into prominence as soon as *any* mixture that approximately resembles a tissue ash is introduced into the arc. King¹¹ pointed out that the presence of easily ionizable substances influence the apparent line intensity—notably in the case of calcium. Papish and O’Leary¹² have found that the least recognizable quantity of chromium when introduced into the arc as chromic acid was 0.001 mg., but the same element in fused alumina produced a spectrum much more intense and was recognizable to the extent of 0.00006 mg. Our work with the spectrographic determination of urinary lead so far has been in the direction of tracing such spectral vagaries. With all the sodium, potassium, calcium, and magnesium present in urine ash it is not surprising that more lead is apparently found than actually exists. Papish¹³ has coined the term “pulsion” to designate the variation in intensity of spectral lines as conditioned by ionization phenomena. These facts lead Webb (*loc. cit.*) to state that the tissue distribution of

certain elements found by workers who employed carbon or graphite electrodes must be treated with reserve.

It does not seem that these problems are at all beyond solution. On the contrary, it would appear that, while further careful study of electrode conditions is necessary, quantitative spectrography with respect to the heavy metals in biological material can become more definitely a precision method.

In thus reviewing certain phases of analytical procedure which need further careful investigation, I have not wished to magnify the difficulties of approach, nor to minimize what has been accomplished so far. One cannot but feel confident however that the advances made in industrial hygiene will justify all the care and attention that is devoted to insure precision of measurement.

Formate Ricinoleate and Brilliant Green Bile Broths to Detect Coliform Organisms in Pasteurized Milk*

I. C. GUNSALUS AND C. N. STARK

Laboratory of Bacteriology, Cornell University, Ithaca, N. Y.

THE results of most recent studies reported (Swenarton, 1927; McCrady and Langevin, 1932; Stark and Patterson, 1936; and others) indicate that although members of the coliform group of bacteria may occasionally resist the heat treatment employed in the pasteurization of milk, organisms of this group which can survive the pasteurization process are seldom observed. Exhaustive studies made by the New York State Department of Health, as well as those made by other workers, have indicated that coliform organisms were present in approximately 1 per cent of pasteurized milks known to contain these bacteria previous to the heat treatment.

Although bacteria belonging to this group are occasionally found to be able to resist the heat treatment of the pasteurizing process, their presence in pasteurized milk is usually interpreted to indicate recontamination. One of the principal reasons for testing pasteurized milk for the presence of coliform bacteria is the ease with which the test can be made. Although it is well known that bacteria belonging to the *Escherichia-Aerobacter* group are

not, as a rule, disease producers and that their presence in milk does not have the same sanitary or public health significance as does their presence in drinking water for human consumption, the seriousness of permitting pasteurized milk to become recontaminated with any kind of bacteria is readily recognized.

At present either the amylase or phosphatase test is employed to ascertain whether milk has been properly pasteurized, and tests to determine the presence or absence of coliform organisms are used to guard against the recontamination of properly pasteurized milk.

The significance of the presence of small numbers of coliform organisms in raw milk is unknown. All who have tested the various media which have been suggested for use on milk readily recognize that these media do not give as satisfactory results on raw milk as they give on pasteurized milk. Because of this, and since we have no accepted standards for the significance of coliform organisms in raw milk, workers making comparative media studies would do well to use pasteurized milks.

No perfect medium has been or probably will ever be found. It has been shown (Stark and Curtis, 1936) that brilliant green 2 per cent bile

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

TABLE I

Formate-Ricinoleate Broth as a Presumptive Test Medium for the Detection of Escherichia-Aerobacter Organisms in Pasteurized Milk

Series	Date of Test	No. of Samples Tested	No. Positive	No. Confirmed	Per cent of Samples Positive	Per cent of Samples Confirmed	Per cent of Positives Confirmed
I	4/24/36	229	35	34	15.3	14.9	97.0
II	7/23/36	221	69	68	31.2	30.8	98.5
IV	4/ 1/37	205	43	42	21.0	20.5	97.6
Total or Average		655	147	144	22.4	22.0	98.0

broth will permit gas production by certain spore-producing bacteria not known to have sanitary or public health significance in pasteurized milk. How frequently these false test organisms will be encountered in pasteurized milk is not definitely known. Some have criticised the toxicity of formate ricinoleate broth. Bacteria capable of causing false tests in this medium may be found.

Using formate ricinoleate broth as the test medium for the detection of coliform organisms in 655 samples of pasteurized milk, 147 were found to be positive (Table I); only 3 samples, about 2 per cent of the positives, failed to confirm. In this study special effort was exerted to confirm all samples giving positive presumptive results. Before criticising too severely any medium for failure to confirm, one must recognize that failure to confirm does not necessarily prove the positive presumptive test to be false. The isolation of bacteria capable of producing the false test is strong evidence. In this study formate ricinoleate broth con-

firmed in 98 per cent of the cases; in the other 2 per cent (3 samples), slow lactose fermenting coliform organisms were found in 2, and in the other sample non-lactose fermenting bacteria, which might belong to the Salmonella group, or might be Escherichia organisms which had lost their ability to ferment lactose. The detection of weak lactose fermenting strains should be an advantage rather than a drawback for this medium. It is believed by us that pasteurized milk containing Salmonella organisms should be considered unfit for consumption and that a medium which detects these bacteria comes one step nearer to the ideal medium. From these data it is concluded that the presence of organisms in pasteurized milk which are able to cause false presumptive tests in formate-ricinoleate broth are rare. It is realized, however, that false presumptive tests might at times be encountered.

In a comparative study of 221 samples of pasteurized milk (Table II), brilliant green 2 per cent bile broth gave a slightly greater number of positive

TABLE II

Comparison of Presumptive Test Media for Detection of Escherichia-Aerobacter Organisms in Pasteurized Milk

221 Samples Tested 7/23/36

Media	No. of Samples Positive	No. of Samples Confirmed	Per cent of Samples Positive	Per cent of Samples Confirmed	Per cent of Positives Confirmed
Brilliant Green 2 per cent Bile	76	73	34.4	33.0	96.0
Formate-Ricinoleate	69	68	31.2	30.8	98.5

presumptive tests than did formate ricinoleate broth, but the brilliant green bile broth gave a slightly lower percentage confirmation; in certain instances the gas in the positive presumptive tubes was shown to have been produced by anaerobic spore-producing rods.

SUMMARY

Formate ricinoleate broth has been used to determine the presence of coliform organisms in 655 samples of pasteurized milk. Ninety-eight per cent of the positive presumptive tests confirmed; in the other 2 per cent, 3 samples, slow lactose fermenting or related organisms were found.

In comparative tests on 221 samples

of pasteurized milk formate ricinoleate and brilliant green 2 per cent bile broth gave approximately the same number of positive presumptive tests. Brilliant green gave a slightly higher yield of positive presumptives, but some of these were shown to be due to anaerobic spore-producing rods.

New Jersey Health Legislation

WE are indebted to *Health Progress*, the publication of the New Jersey Health and Sanitary Association, for the following summary of important developments in public health legislation in New Jersey:

A marriage bill, which was drafted by the venereal disease committee of the Health and Sanitary Association and sponsored by the State Department of Health, provides that, beginning July 1, 1938, each applicant for a marriage license in New Jersey must present a certificate from a qualified physician stating that a standard laboratory blood test for syphilis has been made and that, in the opinion of the physician, the person either is not infected with syphilis or is not in a stage of that disease which may become communicable.

Another law, effective January 1, 1939, requires physicians to take blood samples for syphilis tests from all expectant mothers at the time of the first examination. Midwives and others are not allowed to take such samples but must call in a physician for the purpose. All birth certificates must include a statement as to whether or not the blood test was made and the date.

Another provision, which is now in effect, provides \$25,000 for the purchase and distribution of pneumonia serum by the State Department of Health.

A fourth provision allows local boards of health to pool their finances for the purpose of lifting the levels of their work and permitting small communities which cannot afford full-time service to employ qualified personnel.

Politics in the Selection of Health Department Personnel

Is There a Remedy?*

WILLIAM PARR CAPES

*Executive Secretary, New York State Conference of Mayors
and Other Municipal Officials, Albany, N. Y.*

BEFORE the question assigned to me can be discussed intelligently, we must know exactly what we are discussing. The use of the word "politics" is bothersome and, unless we determine its exact meaning and application for this discussion, our suggestions may be misinterpreted and therefore misleading. If we define politics as the science of government, which is one dictionary definition, there can be no objection to its use in the selection of health department personnel. If, however, we consider politics as the subservience of the interests of a political party or of interests other than public, which is the most prevalent interpretation, then we have a problem which demands our most serious thought.

Pernicious politics, no matter by whom used, can degrade the personnel of any municipal department. We must not forget, however, that we have several kinds of politics, all of which are equally harmful to efficient public service. Most of us think only of partisan politics, because we hear more about party activities than those of

other groups. In addition we have, for example, personal politics, fraternal politics, racial politics, religious politics, and the politics of professions. Political parties are not the only ones which "play" politics in its reprehensible sense. We have civic organizations, cliques, and professional bodies which do not hesitate to place their selfish interests above those of the public. We have school politics, labor politics, bank politics, insurance politics, and even health politics.

In order that there may be no misunderstanding, I shall assume that the question under discussion is this: What can be done, if anything, to prevent any interests other than public interfering in the selection and retention of efficient health department personnel?

First, qualification for persons eligible for health department service should be prescribed, either by state law or by a state body. Experience in New York State has demonstrated that it is preferable to establish qualifications by a state body. It is exceedingly difficult, if not almost impossible, to prescribe by law satisfactory qualifications which meet all conditions over a period of time. For several years the Public Health Council of New York State has had authority to prescribe by regulation

* Read before the Health Officers Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

the qualification for local health officers or commissioners and public health nurses. A law was enacted at the last session of the Legislature giving to the Council power also to determine the qualifications for dairy and milk inspectors, operators of public sewage treatment plants and public water treatment and purification plants. If such a state body performs its duties efficiently and does not use its power to create a monopoly in the health field or to favor individuals or groups, and the state department uniformly and rigidly enforces the regulations, this state activity will guarantee a minimum of knowledge and experience which every appointee must have. Political or other interests cannot break through this barrier. The success of this plan depends upon the reasonableness of the regulations and their impartial enforcement. With such a plan in effect the number of applicants is reduced to those who have the knowledge and experience to perform their duties properly. Under it no political or other interest can demand, for instance, that a bartender out of a job be appointed milk inspector or the operator of a sewage disposal plant.

But this alone is not enough. Proficiency among those who are able to meet the prescribed qualifications is not uniform. Therefore, if we are seeking the best, we must put into operation some plan which will make it possible for the appointing officer to select the most proficient of those qualified. No better plan for doing this has yet been devised than civil service. I know the drawbacks and weak points of civil service, but I am convinced that these can be eliminated by proper laws and good administration. If local civil service commissions are effectively supervised and aided by an efficient state commission, and if the local body coöperates with the appointing officer in an effort to make available by ap-

pointment only the best qualified persons, then the opportunity for favoritism and the establishment of mediocre eligible lists are reduced to a minimum.

Much of the criticism of local civil service commissions can be eliminated by the adoption of two comparatively simple plans.

First, the prevalent inability of local commissions to prepare proper examinations for technical positions, such as those in health departments, and to rate papers properly can be remedied by the establishment in the State Civil Service Department of a municipal advisory bureau. The staff of such a bureau could have available technical experts to assist local commissions in preparing proper examinations, and both the staff and experts could aid in rating the papers.

Second, local commissions should assist the local appointing officer in every way possible in obtaining the services of the kind of person he feels he needs to fill the position. This can be done by the local commission conferring with the appointing official when a request is made for the establishment of an eligible list, and learning what qualifications are essential for the job. In performing this duty the local commission should be careful to impress upon the appointing official that it does not want to know what person he desires to fill the position, but what kind of a person is necessary.

The efficient administration of a proper civil service law not only will help health departments to obtain good officials, but also to retain them. A proper statute impartially administered insures tenure of office during good behavior and satisfactory service. However, legislators are being constantly importuned by various groups of civil service employees to build a bomb proof wall around them so that it is almost impossible to remove them

except for some very grave offense. As a result, dry rot enters into the service and the incentive for meritorious service is destroyed. Health department heads must join with other administrative officials in constantly and vigorously opposing such legislation.

The third suggestion I have to offer relates entirely to the retention of an efficient health department personnel. This is just as important as the selection. A department which can retain an efficient personnel will have fewer selections to make. A health officer, food inspector, water superintendent, or any other official in a health department may have all of the preëntry qualifications prescribed. He may also be the best equipped by knowledge and experience as shown by his civil service rating. However, as he continues in the service, he is liable to retrogress or become infested with the termites of indifference unless he keeps abreast of the times by constant study. Experience has demonstrated that in-service and extension training services are the most effective ways to keep officials alert, progressive, and skillful.

A study and observation of municipal administration in New York State revealed a few years ago that the goal of perfection sought was not being approached as rapidly as the public demanded and the officials desired. It was found that municipal servants were not uniformly proficient, and that practically nothing had been done to help the new official know his job. Experience alone had been teaching the official the daily routine of public service, and although experience was a competent and exacting teacher, it was also slow and expensive. The problem was solved by the gradual establishment by the New York State Conference of Mayors and Other Municipal Officials of training schools for officials in service. Following the successful demonstration between 1928 and 1935, the

University of the State of New York granted to the officers of the Conference of Mayors a charter incorporating the Municipal Training Institute of New York State as an educational institution to operate the municipal training schools. We now have in New York State the equivalent of a municipal university offering 20 courses of practical and systematic instruction in municipal government to 15,000 employees. We have to date operated more than 300 training schools which have been attended by more than 47,000 municipal officials. Among these schools are one for each of the following groups of health officials: milk and dairy inspectors, water superintendents and plant operators, sewage disposal plant operators, and food inspectors.

To supplement the training the officials receive in these training schools, we are now developing in New York State an extension training course for each group. The foundation of this course is a monthly information bulletin. The material for these bulletins is supplied by the local departments and consists of articles describing any new plans or changes in plans, or policies, new developments in work, changes in organization or financing work and new problems, ideas and theories. In effect, the staffs of all the departments in the state have a monthly round table by correspondence at which they present and discuss their work and developments during the previous month. The schools teach the attending official the fundamentals of his job; the extension courses keep him informed of new developments in his work between school sessions.

These schools and extension courses have reduced the costly apprenticeship period of public officials, decreased municipal administration expenses, and are lessening public dissatisfaction with municipal services. They have raised the standard of municipal service,

lengthened the tenure of office, reduced personnel turnover, increased the efficiency of officials and employees, and are gradually convincing the public, including the various interests mentioned in the beginning, that municipal service is not just a political job, but a technical and highly specialized work.

A program of qualification, examination, and training is in my opinion the best so far devised to prevent political or other interests than public interfering in the selection and retention of efficient health department personnel. It is not spectacular, but it is practical. The program as a whole is unusual. I

know of no state or municipality which has in operation all of the recommendations. Several governmental units have adopted one or two of the suggestions and have demonstrated their practicability and value. Few of these, however, can boast of such efficient administration as is necessary to produce desired results.

The program carries with it no guarantee of perfection. It provides the machinery by the operation of which the results sought may be obtained. The more proficiently the machine is operated, the better and more permanent will be the personnel.

Whooping Cough Most Intractable of Childhood Diseases

AT the beginning of the Twentieth Century every one of the 4 principal communicable diseases of childhood (measles, scarlet fever, whooping cough, and diphtheria) was an important cause of death, whereas, at the present time, each is a minor cause. Diphtheria, in the 5 year period 1900-1904, so far outranked the 3 others that it caused more deaths than did all 3 combined. With a death rate in excess of 40 per 100,000 population, in the year 1900, this disease just escaped inclusion among the 10 leading causes of death in the country.*

With the passing of more than one-

third of the century, however, the picture has changed. Not only have the death rates from these diseases been materially reduced, but there has also been a change in their relative rank. Whooping cough is now the leader and takes a toll of 3 lives to every 2 charged to diphtheria.

The following table shows the death rates from each of these diseases for the 5 year periods 1931 to 1935 and 1900 to 1904.

*Average Death Rates per 100,000 for the Principal Communicable Diseases of Children
Original Registration States
1931-1935 and 1900-1904*

Cause of Death	1931 to 1935	1900 to 1904
Measles	2.0	10.0
Scarlet fever	2.1	11.8
Whooping cough	2.9	10.7
Diphtheria	2.0	32.8

* In an area consisting of 10 states and the District of Columbia. Reliable data on the mortality from individual causes of death are not available for the rest of the United States for the year 1900.

—Stat. Bull., Metropolitan Life Insurance Company, Apr., 1938.

A Sanitary Study of Commercial Laundry Practices*

LLOYD ARNOLD, M.D., F.A.P.H.A.

Department of Bacteriology and Public Health, University of Illinois College of Medicine, Chicago, Ill.

WE have applied our knowledge of sanitary sciences to restricting the distribution of bacteria in water, milk, and food. The present paper is a report of a year's study of the sanitary practices in 54 laundries. The purpose of the study was to ascertain the usual practice and then to develop methods of procedures to overcome the sanitary errors, if such existed.

The washing formula can be subdivided into two large groups, one using a high temperature for white clothes and fabrics, the other requiring a low temperature formula to preserve the color of textiles which would be altered by high temperature. Any washing formula must prevent loss of tensile strength, and the whiteness retention must be preserved. Fabrics must not lose more than 10 per cent of their tensile strength after 20 complete washings, and the whiteness retention tests cannot show more than 6 per cent loss. The formula studied by us conformed to these tests. We were concerned only with the bacterial counts of the wash waters and the textiles in the laundry process.

A family's weekly laundry bundle is subdivided into approximately 16 classifications. Each classification receives a different treatment. Space does not allow us to go farther into this aspect of the washing technic, but for the purposes of this report we shall for convenience and simplicity consider but 2 of these formulae: the high temperature white clothes and the low temperature colored clothes formulae.

Tables I and II give the high and low temperature washing formulae. The flush is the wetting process and consists of the addition of water. This is followed by 4 suds. The washing apparatus is drained after each operation. The 4 rinsing processes are to remove the detergents used in the washing process. The last or sour rinse is to remove the residual soaps which may be retained in the clothes. The whole procedure consists of 4 detergency operations for cleansing the clothes and a similar number of rinsing operations to remove the detergent.

Tables I and II also give the purpose of each operation, the holding time, temperature, and the average bacterial count per c.c. of the wash water. The bacterial count is based upon a year's study of 2 laundries, each was tested twice weekly throughout the year.

The high temperature washing proc-

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

ess does not present many sanitary problems. A temperature of 165° to 175° F. with a chlorine (bleach) concentration of 0.01 per cent in the fourth suds, held for 15 minutes is an effective germicidal process. This temperature prevents accumulation of bacteria inside the washing apparatus. Any deposit of insoluble material does not contain living bacteria. Approximately 75 to 80 per cent of the total wash in laundries is processed by this high temperature method.

The low temperature washing formula presents some interesting sanitary problems. The preservation of the fabrics, silks, woolens, and the colors

necessitates a low temperature washing procedure, too low to be of significance as a bactericidal procedure. Dilution by repeated washing and rinsing is the principal mechanism of removal of bacteria from the clothes. The last operation used by laundries consists of the addition of some sour or weak acid to remove the residual detergent and brighten the colors of the clothes. We have found that this operation can be used as a bactericidal process. If the sour used brings the hydrogen-ion concentration down to pH 3.8 to 4.2 and is held for 5 minutes, there is a reduction of the bacterial count. We have therefore utilized this common

procedure and adapted it so as to make a germicidal agent. This requires a carefully controlled operation; the colorimetric determination of the hydrogen-ion concentration must be carried out on each load of clothes washed.

The following sour s have been studied:

Sodium Acid Fluoride
Sodium Silico Fluoride
Ammonium Acid Fluoride
Ammonium Silico Fluoride
Acetic Acid

Table III gives the average amount of each sour to be added per lb. of clothes in order to obtain the required hydrogen-ion concentration. The buffered sour s are safer and more satisfactory. The organic acids can be added in excess and will then reduce the tensile strength of the textiles in the wash.

TABLE III

One and One-half Grams of Each of the Following Sour s Were Added per lb. of Clothes—Hydrogen-ion Concentration and Bacterial Count Determined at 5 Minutes' Holding Time

	pH	Bacteria per c.c.
Sodium Acid Fluoride	4.3	40

F	612,550	11

age number of bacteria cultured from wooden cylinders per sq. in. of surface before and after cleaning from 6 laundries. Table V gives a method of cleaning cylinders which we have found to be very effective and practical. Sodium silico fluoride dissociates at high temperature and acts as a solvent for the calcium soap residues as well as a germicidal agent. Twenty minutes holding time at 190° to 195° F. in the presence of this acidity destroys the bacterial flora in deposits. Rinsing at high temperature, followed by the use of caustic soda to neutralize the acids in the wooden cylinders, followed again by hot rinses, leads to a clean cylinder with a very low bacterial count on its surface.

TABLE V

A Method for Cleaning Wooden Cylinders in Laundries

Procedure	Purpose	Time Minutes	Temperature Degrees Fahrenheit
2 lb. Sodium Silico Fluoride	Acid to dissolve insoluble soap residue and kill bacteria	20	190-195
Hot Rinse	Remove residual acid and destroy bacteria	5	170
Hot Rinse	Remove residual acid and destroy bacteria	5	170
2 lb. NaOH	Neutralize acidity and remove residue	20	190-195
Hot Rinse	Kill remaining bacteria and remove residual chemicals	5	170
Hot Rinse	Kill remaining bacteria and remove residual chemicals	5	170

The low temperature washing formula allows insoluble residues to be built up on the inside of the machines. The cylinders become coated with insoluble calcium soaps and other materials which harbor many living bac-

Table VI gives the results of bacterial counts of the last souring rinse from 3 laundries using the same washing formula before and after the cylinders were cleaned. Table VII records an average low temperature

dirty cylinder wash. It is self evident that bacteria are being added from some source to the wash waters. The 4th and 5th rinse waters contain more than twice the number of bacteria that were present in the 3rd rinsing operation. The souring process was not effective because of the inexhaustible bacterial reservoir on the surface of

washing process with bacterial counts per c.c. of the wash water, using the same machine before and after cleaning of the cylinder. It is apparent that the sanitary efficiency of the process is not satisfactory when the cylinder acts as a bacterial reservoir during the procedure. We wish to call attention to the irregularity of the counts in the

the cylinder in contact with the clothes.

There is a seasonal variation in the bacterial counts of clothes received by laundries. During the warm months the bacterial flora of clothes is much higher than during cold months of the year. Table VIII gives the summary of a year's cycle by months in one laundry studied.

TABLE VIII

Laundry B

July	14,063,111	27,149	427	88° F.
August	18,514,530	27,122	430	95° F.
September	16,288,870	36,378	426	91° F.
October	2,055,090	55,188	388	72° F.
November	1,203,697	16,050	216	56° F.
December	850,045	19,646	119	48° F.

Staphylococcus albus is the predominant bacterium in the flora in all wash waters from flush to the after sour rinse. This is the microorganism that increases in the clothes during the warm weather months of the year. The flora in the after sour rinse are usually large china white colonies of *Staphylococcus albus*.

A part of this high count after the souring operation was due to dirty cylinders. This is shown in Table IX. If the low temperature washing formula is used several times each day a wooden cylinder will build up a surface deposit in 4 to 6 weeks that will materially influence the sanitary quality of the washing process. We have found that if a cylinder is cleaned properly, and then once a week this cylinder is used for high temperature washes, it will perform in a sanitary manner for at least 6 weeks before it will show by both surface swab and rinse water high bacterial counts. If the clean cylinder is used on alternating days for high and low temperature washes, it will remain clean for several months.

TABLE IX

Influence of Clean Cylinders on the Average Monthly Bacterial Count During Summer Months

Low Temperature Washing Formula

	July, 1937	August, 1937
Cylinders cleaned:	May 1, 1937	August 1, 1937
Flush	14,063,111	4,536,962
Last Rinse	27,149	27,122
Sour Rinse	427	218
Maximum Monthly Temperature	88° F.	95° F.

Table X gives a résumé of a series of experiments to determine the relationship between the bacterial counts in the water and the bacteria on the clothes. We are more interested in the bacteria remaining on the wearing apparel than in those in the wash waters. Test clothes were put into the wash clothes and removed after

TABLE X

various operations. Five square inches were cut out under aseptic precautions and bacterial counts made on each sq. in. sample. The technic was to suspend the inch square sample in 10 c.c. sterile saline and shake in a machine for 10 minutes. One, 2, and 4 c.c. samples were used for shake plate counts and the inch square fabric was transferred to a sterile Petri dish and covered with melted cooled nutrient agar. The bacterial count was calculated and the last column represents averages of these experiments. Bacteria are removed from the clothes during the washing process as would be expected from the wash water count. The extraction operation (centrifugation) removes the excess water and we found this process was very effective in removing bacteria. The extraction operation lasts 10 minutes. The remaining bacteria are destroyed by ironing.

We have conducted numerous ironing experiments. We have substantiated previously published reports from other sources that the high moist temperature is an effective process in killing bacteria, vegetative forms as well as spores. We have added bacteria (*B. subtilis*, *B. welchii*, *B. megatherium*, *Staphylococcus*, *Streptococcus*, *B. coli* and *B. pyocyaneus*) to

fabrics in high concentrations before passing through the ironing machines. All fabrics—using 12 inch square pieces submerged in broth flasks—were sterile after ironing.

We do not feel that the demonstrated efficiency of the ideal ironing process should be depended upon to remove large numbers of bacteria from clothes. This is similar to expecting pasteurization to make dirty milk wholesome for human consumption.

SUMMARY

The high temperature washing formula used for white clothes and fab-

rics has sufficient temperature and holding time to insure a safe procedure from a public health standpoint.

The low temperature washing formula used for other classifications requires more attention. The cylinders or machines need frequent cleaning to prevent bacterial accumulation on their surfaces. The souring operation must be carried out at a hydrogen-ion concentration of between pH 3.8 and 4.2 to insure low bacterial counts.

The extraction and ironing procedures remove or kill the residual adherent bacteria in all instances studied by us.

Supervision of Food in New York City*

A. LICHTERMAN, PHAR.D.

*Acting Director, Bureau of Food and Drugs, Department of Health,
New York, N. Y.*

IN anticipating the supervision of food in New York City, one must familiarize himself with the quantity and type of food which is received daily; the geographic confines of the city, and the points of entry. At the outset, consider a train of railroad cars, each loaded with food containing approximately 20 tons. A train of this sort which is 2 miles long, or the equivalent of 200 city blocks, would represent the approximate food bill per day for the City of New York. There is about 28,578,425 lb. of food consumed daily in New York City.

New York City comprises an area of approximately 319 square miles, with a population of 7,294,000 persons and 1,000,000 commuters and daily visitors. There are about 120,000 food establishments of all kinds, of which 25,000 are wholesale or manufacturing plants. There are 733 piers within the borders of this city where 327 ocean liners dock weekly from all parts of the world.

The milk supply for New York City is received daily from a milk shed which comprises 7 states and is within a radius of 500 miles of New York City. To furnish this milk supply, there are 62,286 establishments outside of New York City and 475 estab-

lishments within the city and the metropolitan area.

To have some control over this vast food supply, it is essential that a detailed knowledge of the points of entry of food be part of the equipment of the Administrator. He must be able to dispatch inspectors on short notice to all these points, in order to keep unwholesome or questionable food from entering the food channels. This procedure is more exemplified by the activity of the Bureau of Food and Drugs during the early part of 1936 when we were concerned with keeping condemned food from the flooded areas from entering our city. Due to precautions taken, four cars holding 80,000 lb. of semolina flour, one car holding 20,000 lb. of butter, and large quantities of meat were seized and condemned before they were able to enter food channels.

It is essential in the supervision of a food supply to know the geography of the city, especially the market areas and districts where large quantities are handled and stored. With such information on hand, it is relatively simple to conduct periodic surveys of these establishments in the given areas.

METHODS OF CONTROL

Control of all food establishments of the City of New York rests with the Bureau of Food and Drugs, of the Department of Health. The method whereby control of these food estab-

lishments is maintained, consists of dividing the city into inspection districts, each being supervised by an inspector. Major control work is carried on through seasonal activity and planned projects. Table I indicates the time of the year when special surveys are undertaken of the different foods and food manufacturing plants.

In addition to the activity of the Bureau of Food and Drugs in connection with seasonable activities and planned projects, inspectors of this bureau are required to make routine inspections of establishments under permit to conduct restaurants, bakeries, soft drinks, milk, cheese, butter and eggs, shellfish, preserved meats, etc. Also, the investigation of complaints involving food establishments requires the attention of the food inspector. During 1936 more than 12,000 complaints were investigated including every conceivable subject concerning food or sanitation in food establishments. Piers, railroads, terminals, market areas, and places where food enters the city are covered by the inspector of the particular district in which the receiving points are located.

METHODS OF INSPECTION

The essential sanitary conditions to be determined in a food establishment by an inspector are:

1. Adequate toilet facilities with running hot and cold water
2. Adequate refrigeration for perishable foods
3. Clean utensils and adequate sterilization
4. General cleanliness in and about the plant
5. Undue exposure of foods to contamination by dust, dirt and flies
6. Removal of obnoxious odors
7. Hygienic habits of the operators

A good food inspector is able to recognize quickly whether the operator is conducting his business in accordance with the fundamental sanitary laws, or is careless or slipshod in his methods. Merchandise stored in corners or hidden behind boxes involves spoilage and undue waste; cans standing to one side or tipped on shelves indicates swells; unclean labels on cans may indicate leakers or food from salvage stores; sediment in bottled goods serves to indicate improper storage, manufacturing, packing or perhaps spoilage.

Records, dealing with the receiving

and storing of raw products and the distribution thereof, should be examined in all manufacturing plants. Information of this nature often uncovers improper methods and practices on the part of the food processor.

EDUCATION OF THE FOOD DEALER

Dealers in food generally are not acquainted with the health aspects of handling, storing, or manufacturing of foods, nor the reason for the regulations promulgated to control these conditions. A program of education whereby representative food organizations are called to meetings of their respective groups should be inaugurated. At these conferences, officials of the Food and Drug Bureau give detailed information explaining the health significance of the regulations governing the respective industries. Open discussion is held after presentation of the initial talk. Often new ideas are expressed by the industry which are of interest to the health officer and reveal problems in health control.

When the administrative office has secured the confidence of the industry, information concerning questionable practices is often brought to its attention, which leads to corrective measures being taken. The results of such conferences tend toward an understanding for better coöperation between the industry and the health administrator, ultimately benefitting the public at large.

COÖPERATION WITH OTHER HEALTH AGENCIES

Food control administrators must of necessity develop a feeling of confidence in their fellow workers in departments within the city, and other municipal, state, and federal control agencies. The policy of the Bureau of Food and Drugs of the New York City Health Department has been to co-operate and give every assistance to

such agencies. The principal concern is to protect public health. This spirit of coöperation makes the food dealer realize that not only has he the city authorities to contend with but also the other local, state, and federal agencies.

PERSONNEL TRAINING

Besides the general office and field training of the new inspector, provision is made for further instruction once he has obtained the fundamentals of food and sanitary work. The personnel of the Bureau of Food and Drugs has at times taken advantage of courses at New York University, Cornell University, Massachusetts Institute of Technology, and special courses given by the State Department of Agriculture at Albany, N. Y. At present there is one man assigned to a full 1 year course in sanitary and food control at Massachusetts Institute of Technology. In addition, 10 men are assigned to take a similar short course of 8 weeks' duration at New York University. Those who have had the benefit of such courses are required to present papers at Inspectorial Meetings which are held semi-monthly. Free discussion is encouraged and better understanding developed among the personnel regarding the scientific principles of sanitary inspection and food control.

RECORD KEEPING

Records of work accomplished and findings of the inspectors in the course of their daily routine must be kept in order that results may be tabulated and future action planned. An instance in which the benefits obtained from the keeping of proper records was brought out in the methods pertaining to record keeping for food poisoning cases. Prior to the inauguration of the new system the procedure was to total the number of investigations made relative to cases where food was suspected

of causing illness. This total was accepted as the number of food poisoning cases for the current year. The present method involves the classifying of reported cases of alleged food illness into 3 groups. The first group is known as "confirmed" or "proved" food poisoning cases. The second are those which are "doubtful," and the third are those instances which are proved to be "non-food" poisoning cases.

CONCLUSION

The City of New York has a vast supply of foodstuffs coming to its more than 7,000,000 population daily. The responsibility of keeping this food supply available and wholesome at all times rests largely with the Bureau of Food and Drugs of the Department of

Health. Proper control has resulted in not a single epidemic or severe outbreak caused by food for many years.

The modern health officer realizes that a safe food supply means a healthy community; that with a safe food supply it becomes his function, through educational methods, to bring to the attention of the people of his community how to use this food so that they may get the best nutritional value therefrom. Food dealers should be made to realize that the health inspectors' function is to advise and teach them the proper manner in which to conduct their food establishments. This coöperation between the dealer and the department of health leads to a safe food supply.

The Nutritionist in a City Public Health Program*

SOPHIA S. HALSTED

Nutrition Director, Department of Health, Detroit, Mich.

DETROIT became interested in nutrition about 1921 when the whole nation was concerned with improving the physical conditions revealed by examinations for military service during the World War. If improvement was to be shown in the rising generation, malnutrition was one of the enemies which must be conquered. It seemed quite logical to begin with the school children of the city, and consequently a plan modeled after the very popular procedure of Dr. William Emerson was instigated.

All of you are doubtless familiar with those early methods of combating malnutrition and the results obtained therefrom. The limited number of children who could be reached by such a program showed marked improvement in nutritional status, but unless a youngster was extremely emaciated, there was not much opportunity to include him in the activities. Correction rather than prevention was the usual objective in those early programs.

As the science of nutrition developed, it became apparent that work which was limited to underweight children was wholly inadequate. The poorly fed obese youngster came into the picture and presented his particular problems;

deficiency diseases were recognized and studied; prophylactic measures were carefully mapped out based on the results of scientific investigation; many things other than body weight began to enter into any consideration of malnutrition.

The trend toward preventive measures gained momentum and our nutrition program was reorganized on an entirely different basis. Assuming that all children should know the essentials of good nutrition and should be taught correct health habits in their early years, an effort was made to plan those activities which would include normal as well as abnormal children. Consequently the standard program of classes for the malnourished children was broadened to include all of the children in a chosen grade or section. Supplementary feedings were abandoned. Emphasis was placed on the formation of good health habits and attitudes rather than on gain in weight. Children who failed to grow according to established standards were subjected to intensive follow-up work. They themselves were interviewed individually and their parents were invited into conference with the nutritionists. Interest of the whole school was aroused by the display of posters and exhibits, articles in the school papers, and campaigns in the lunch rooms. The requests for the classes soon exceeded the numbers which could be handled with the limited

* Read at a Joint Session of the Child Hygiene, Foods and Nutrition, and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 9, 1937.

personnel available, and it was necessary to confine the activities to a few selected schools each semester.

In order to broaden the scope and increase the efficiency of nutrition work in the schools, it is hoped that in the near future a coöperative plan involving the classroom teacher and the trained nutritionists as consultants may be placed in operation.

While our school activities were undergoing this evolution, it became increasingly apparent that we were missing a golden opportunity to teach normal nutrition in our own prenatal and child welfare clinics. During the summer of 1930 therefore, a nutritionist was assigned the task of organizing an experimental program in these clinics. Modestly beginning with a group talk once a week in the waiting rooms, this prophylactic service rapidly proved its value. The teaching of normal nutrition has come to be considered an integral part of good prenatal care, and plays such an important rôle in the physical growth and development of children that a nutritionist is now included in the personnel of each clinic. At the present time 5 staff nutritionists divide their time among the 7 health centers and specialized divisions of the department. Their schedules are so planned that it is possible for them to cover approximately 66 per cent of the prenatal and 41 per cent of the baby clinics with regular nutrition service. Normal nutrition with all of its ramifications—food preparation, budgeting, habit training, etc.—is routinely discussed with all patients admitted to the clinics. Individual interviews, group discussions, posters, and exhibits are the technics most frequently used. In addition to normal diet instructions, the nutritionists coöperate with the clinic physicians in planning and explaining to patients any special diet orders that may be deemed necessary. Thus the doctor can use the services of

a scientifically trained person to execute his dietary recommendations. In addition to the work done in the clinics, the nutritionists follow their conferences with visits to the homes of patients. Actual demonstrations of food preparation and detailed planning of budgets can be done better in the seclusion of an environment familiar to the individual. A trip to the market with a housewife is an excellent object lesson in food selection.

For the clinics which are not included in the regular schedule of nutrition work, the nutritionists are on call as needed. Cases requiring help with food problems may be referred to them either by telephone or in writing. Such refers are handled through home visiting.

As the official health agency in the community, the health department is frequently called upon to supply speakers for various organizations and interested groups in the city. Requests for talks on nutrition have been increasing with the growing food consciousness of our population. Last year 28 such requests were handled by the nutrition division in addition to the weekly radio broadcast which has been conducted for the past 3 years. Through the speaker's bureau and our radio programs, we reach a group of people that would be entirely missed if our activities were confined solely to the schools or to our clinics.

In addition to the work done with lay people, the services of the nutritionists of the Health Department are available to any agency in the city who wants to use them as consultants. Frequent committee meetings, conferences, and interviews are held, together with occasional group talks to workers in related fields. To avoid duplication of efforts in nutrition work, close co-operation among the nutritionists in the community is maintained.

The public health nurse working in

a generalized program is invariably called upon to discuss food and diet problems with the families with whom she comes in contact. The assistance she is able to give them in solving their nutrition difficulties should represent the same high standards of accuracy and timeliness as those of her nursing technics; therefore one of the most important phases of our program is the attempt to keep the entire staff of the department well informed and up to date in the science of nutrition. To maintain close enough contact with all field workers to insure uniformity in information given to the public, a plan of staff education has been evolved. At least once each month the nutritionist meets with the nurses working in her district for a discussion of food problems. Case studies, reports of recent literature and scientific meetings supply the material for these group conferences. Individual nurses and other personnel are encouraged to call upon the nutritionists for help either for themselves or for the families under their supervision. Staff members ask for all sorts of help—explanation of a dietary order they have received from their physician, recipes and menus for use in their own homes, literature to send to their friends, food budgets to make their money stretch a little farther, reference material for classwork, and so on. Every one of these contacts provides the opportunity to spread the gospel of good nutrition, and they are easily utilized as teaching situations.

Realizing the growing importance of prophylactic measures in nutrition work, the American Dietetic Association in 1932 made a recommendation to the hospitals sponsoring courses for student dietitians that their training periods could be greatly enhanced by an affiliation with a public health agency doing nutrition work. Consequently the three hospitals* offering such training in Michigan requested

the Detroit Department of Health to provide such an affiliation. Giving these young women a glimpse of the possibilities of preventing many dietary disturbances and showing them the relationship between the patient in the hospital and the members of his family has been of immeasurable benefit both professionally and personally to these potential nutritionists. The 2 weeks spent with the Health Department is eagerly anticipated by most of the students and their presence brings to us a freshness of viewpoint that could not be achieved in any other way.

One of the requirements for the master's degree in public health from the University of Michigan is that the candidate shall have 3 months of practical experience in a recognized agency. When a course was planned, leading to an advanced degree in public health nutrition for students with a home economics background, the Detroit Department of Health was selected as the organization in which such students could obtain the required field work. As yet this curriculum is too new to have sent students to us, but within the next year, we expect to incorporate this activity into our program. It is our aim to give these young people experience in the routine nutrition work in addition to providing them with the opportunity to organize and conduct field studies for us. With 3 months of such experience plus the training in public health administration, statistics, public speaking, etc., which they will receive at the university, they should be well equipped to meet the growing demand for public health nutritionists.

The success of any nutrition program is largely dependent upon the people who are chosen to plan and administer it. Any sort of educational work re-

* Henry Ford Hospital in Detroit, Harper Hospital in Detroit, and University of Michigan Hospital in Ann Arbor.

quires adequate academic preparation and experience. Nutrition is a science whose subject matter is detailed and complex. The well trained nutritionist is a college graduate who has had training in the fundamental sciences—physics, chemistry, and biology—before she begins to specialize in nutrition. Her undergraduate work is done in an institution in which the home economics course is recognized by professional workers in the field. Her academic work is then supplemented by 1 or 2 years of practical experience. For membership in the American Dietetic Association, the professional organization for nutritionists and dietitians, 2 years of practical experience including a period of internship in an approved hospital is obligatory.

In addition to these professional requirements, there are certain personal qualifications necessary. Good health should certainly come first on the list since she must be a good example of the principles she preaches. With obvious nutritional defects herself, such as overweight or underweight, poor physical development, or lack of vitality, her teaching will be discounted by those with whom she comes in contact. Emotional stability and poise, because they indicate mental health, are characteristics which she must possess. The capacity to work well with all kinds of people in all walks of life is important for anyone, but for the nutritionist it is indispensable. Adaptability and ingenuity in making use of available resources is a decided asset. The person who has to wait for ideal working conditions and perfect equipment has no place in the public health field. Sympathetic understanding of and tolerance for individual variations and differences is essential to success in dealing with human beings. The true scientist, and that is what the nutritionist should be, looks at facts and bases judgment upon them rather than

upon personal prejudices and feelings. Because nutrition is a rapidly developing science, the nutritionist must be ever alert to the advances being made. She must keep posted not only in her own field but in all fields directly related to her profession. She must have the initiative and interest which will stimulate her to constant study and professional growth.

If a nutritionist has these professional and personal qualifications, she will be actively interested in her professional associations and organizations. Membership in such groups is evidence of her appreciation of the need for constructive progressive advancement in her chosen field of activity. Unless she has some means of contact with other workers in the same and allied fields, her educational program will not have the breadth of vision which should be its outstanding characteristic.

The objective of the nutrition service in the Detroit Department of Health is the attainment of the best possible state of nutrition for the citizens of the community. To achieve this end, there are several aims guiding the activities of the nutritionists:

1. To arouse an interest in and an appreciation of the relationship existing between good health and normal nutrition
2. To maintain a source of authentic and reliable information on all matters pertaining to the feeding of people
3. To prevent and correct nutritional deficiencies within the limits of an educational program
4. To use every available opportunity to teach sound nutrition principles and encourage the use of those principles in every day living

The methods used in attaining these aims are identical with those employed in any phase of health education. Group discussions in clinics, schools, and community organizations can serve to arouse interest in nutrition; individual conferences, either personal or by correspondence, offer more specific help, and are probably the most effec-

tive technics; radio talks and printed literature have their place in supplying large numbers of people with general information; consultation service for schools and other agencies provide the means for much indirect teaching; and coöperation with educational institutions serve to make future professional workers aware of the possibilities inherent in their chosen field of activity. Posters and exhibits, carefully planned and judiciously used, can contribute materially to the teaching of health subjects. Any well rounded public health nutrition program should make use of a combination of any or all of these

devices. The needs and facilities of the community must be considered in determining the most effective means of disseminating educational material.

If science is to counteract faddism, the official health agency in any community must be prepared to dispense authentic and reliable information on all subjects pertaining to health. Nutrition is no exception, and with the developing food consciousness of our population, the trained nutritionist is rapidly becoming an essential member in the personnel of all organizations which are striving adequately to meet community needs.

Schick Reactions in Students of Medicine

H. C. PULLEY and MOYER S. FLEISHER

Department of Bacteriology, St. Louis University School of Medicine, St. Louis, Mo.

DURING the 7 years 1930-1936, each student in the sophomore class at St. Louis University School of Medicine was Schick tested, and records have been kept. Information has been collected regarding Schick reactions of 816 students, the majority of whom were between the ages of 22 and 27; a few, only 20 or 21, and an insignificant number ranged to 29 years.

Information has been obtained regarding the place of birth and home address of each student as well as personal history of diphtheria, immunization against diphtheria, and administration of antitoxin for therapeutic or prophylactic purposes.

For the purpose of the present study the individuals have been divided into 4 classes according to previous residence on the basis of (1) continuous residence in a larger community, (2) continuous residence in a smaller community, (3) birth in a larger and later removal to a smaller community, and (4) birth in a smaller and later residence in a larger community. Any community of 50,000 population or more has been classed as large, and one of less than 50,000 population was classed as small. In our first attempts to classify according to size of the community we set up 3 classes, 50,000 population and more, between 50,000 and 10,000, and less than 10,000, and 6 further classes as regards place of birth and later residence. It became apparent that the 4 classes listed

gave a simpler, and at the same time a true picture of the occurrence of positive and negative Schick reactions in relation to residence. The 4 groups were suggested largely by the percentage figures of Schick negative reactions among those giving no history of diphtheria or of immunization.

In tabulating the history of the individuals in relation to diphtheria, administration of antitoxin, or in relation to immunization, we have set up initially 7 classifications:

- a. Those who had had diphtheria and immunization (it is not always clear whether these individuals received only antitoxin or both antitoxin and some active immunizing agent)
- b. Those who had had diphtheria but had not been treated with any agent to produce active immunity
- c. Those who had received toxin-antitoxin mixture to produce active immunity
- d. Those who had received injections of unknown nature to produce active immunity
- e. Those who had received prophylactic injections (presumably antitoxin)
- f. Those who had received antitoxin (not having had diphtheria)
- g. Those giving no history of any therapeutic or prophylactic treatment

Certain of these groupings may seem unnecessary, but they may have certain value. In the tabulations the various original groupings relating to history have been combined so that larger and more inclusive groupings are presented as well as the smaller ones. Thus, in a second part of Table II, all individuals having had a diphtheritic infection

TABLE I

Distribution by Residence of the 7 Annual Student Groups

Residence	Year →		1930-31		31-32		32-33		33-34		34-35		35-36		36-37		Total	Average
			%		%		%		%		%		%		%		%	%

or having received treatment possibly leading to active immunization are listed in one group (*i.e.*, all who might have developed an acquired active immunity), while all others who might not have acquired active immunity through active immunization or through infection are listed in a second group. In Tables III and IV only the figures relating to these 2 summarized groups are presented.

In this group of 816, 72.2 per cent (590) give no history of diphtheria or immunization, while 11.7 per cent (96) give a history of diphtheria. Only 17

per cent (139) of the individuals reported having received active immunization (this includes the group who had diphtheria and were immunized but not those who had diphtheria with no history of active immunization). Only 10.5 per cent reported active immunization but no history of diphtheria, while 5.4 per cent (44) were passively immunized.

Table I shows the distribution by residence in each annual group observed. There is sufficient similarity to justify the assumption that the material is reasonably homogeneous.

TABLE II

*Occurrence of Schick Reactions in Relation to Residence and Past History**Part I*

		68.1%		83.7%		82.7%		87%		25.3%		62.5%		60.3%		68.1%

On the basis of residence in larger and smaller communities, and without regard to the previous history of diphtheria, it will be noted (Table II, Part I, Totals column) that the percentage of negative Schick reactions decreases as we pass from residence in larger communities to residence in smaller, and a sharp drop in Schick negative individuals may be noted when we pass from those who resided for some portion of their life in a larger community. Although in some categories the numbers of individuals are too small to warrant definite statement, there appears the suggestion (Table II, Part I, Columns c and d) that even among those exposed to active immunization the likelihood of developing a negative Schick test is greater with continuous residence in the larger community. Among 45 individuals resident in larger communities 86.7 per cent were Schick negative, while among 34 individuals having lived in smaller communities only 67.6 per cent were Schick negative. The relationship of the Schick reaction to residence is, how-

TABLE II.

more frequent than among those who resided constantly in smaller communities (Table II, Part 2).

In Table III the classification in relation to residence and Schick reaction, for each of the 7 annual student groups is shown. Only the figures for those individuals who lived constantly in larger and smaller communities are considered here, and only the summarized group relating to past history of diphtheria and immunization are presented. The numbers are small in many cases but certain considerations are suggested. While the per cent of negative Schick reactions among those individuals who were exposed to active immunization remains reasonably high during these 7 years, the same cannot be said as to those not exposed to active immunization. In both the group resident in large and that in smaller communities a tendency toward a progressive fall in the number of Schick negative individuals may be noted in the later years of the study.

When the groups of the first 3 years are combined and compared with the group of the last 3 years covered, these

facts become even more striking in view of the greater number of individuals in each group (Table IV).

The combined figures for these groupings again point to the difference between those living in larger communities and those in smaller communities, and there is the suggestion that even among those who had been exposed to active immunization those living in larger communities stand a better chance of being Schick negative.

Among those actively immunized the difference in per cent of Schick negative reactors between those living in larger and in smaller communities is possibly not significant, but it is interesting that the per cent of Schick negatives is slightly higher in both of the residence groups of the last 3 years.

DISCUSSION

One must be cautious in attempting to draw definite conclusions from data as scanty as those presented here, but certain suggestions seem to appear.

As has been pointed out by others, the relative importance of residence in a larger community in relation to devel-

opment of natural immunity becomes evident, and there is definite suggestion that the chances of developing natural immunity in the smaller sized community is relatively less than in the larger community. Thus if we consider the percentage of Schick negatives in 3 groups:

1. All individuals with some residence in communities over 50,000 population (412 total, 136 positive, 276 negative)

2. All individuals with some residence in medium sized communities, between 10,000 and 50,000 population (137 total, 61 positive, 76 negative)

3. All individuals with some residence in smallest communities, under 10,000 population (197 total, 92 positive, 105 negative)

(These three groups of course overlap)—we find that in (1) 66.2 per cent are Schick negative, in (2) 55.4 per cent are negative, and in (3) 53.3 per cent are negative.

The total percentage of Schick negative individuals in the entire group is probably lower than might be expected (64.5 per cent) in this age group.

The per cent of Schick negatives among individuals who had been exposed to active immunization is somewhat low (76.4 per cent). Peculiarly, this low percentage among actively immunized individuals is chiefly affected by the relatively small number of Schick negative individuals among those who had had diphtheria and gave in addition a history of active immunization.

There is also the suggestion that the percentage of Schick negatives is greater in the larger community group than in the smaller even when comparing only those actively immunized. The difference is, however, not great enough to warrant more than the suggestion that maintenance of the Schick negative state may in some cases be dependent upon repeated exposure.

The most striking suggestion which

appears is that there is the apparent gradual diminution of Schick negatives among those who give no history of exposure to active immunity, during the period covered in this study. While the percentage distribution according to residence varies slightly from year to year it is hardly likely that this factor is responsible for the change. It would rather appear that some other factor accounts for the diminution in negative reactions in the successive groups. It may well be that lack of exposure to sub-clinical contact with diphtheria bacilli is responsible. If this tendency is continued in future years (and it is our intention to continue the study of future classes), it raises certain questions of importance in relation to control of diphtheria.

Since it is assumed that the development of immunity to diphtheria in non-actively immunized individuals is related to possibilities for contact with the causative agent, and if active immunization within a community tends to reduce the opportunities for contact of the non-immunized individual with diphtheria bacilli, then those individuals who are not actively immunized must be particularly guarded, or the campaigns for active immunization must be pressed with greater vigor so as to cover as nearly 100 per cent of individuals as possible.

CONCLUSIONS

1. In 7 successive groups of medical students studied, the importance of the place of residence—large or small community—is evident in relation to the development of a negative Schick reaction.

2. The percentage of Schick negative individuals is rather lower than might be expected in such an age group.

3. There is evident the suggestion that the percentage of Schick negative individuals among those not exposed to active immunization, has steadily decreased over the period of this study.

Evaluation of Dental Programs for Children*

J. M. WISAN, D.D.S., F.A.P.H.A.

*American Society for the Promotion of Dentistry for Children,
Elizabeth, N. J.*

A STUDY of public health literature will reveal a need of technics for evaluating dental programs. This void exists in measuring community dental programs and analyzing trends in dental health of individuals, communities, and nations.

This discussion will be limited to two points:

1. The chart recently designated as a national chart for group inspections of school children to determine dental needs
2. The Lost Permanent Tooth Index for evaluating dental programs among school children

NATIONAL DENTAL INSPECTION CHART

This chart (Figure I) is to be used in surveying dental needs of school age children. It is hoped that the designation by the American Society for the Promotion of Dentistry for Children, the American Dental Association, and the proposed sanction of the American Public Health Association, will result in widespread adoption. If this form is used as a basis of dental inspection charts in all local and state dental programs, it will be possible within a few years to make more accurate comparisons and to determine dental needs with greater uniformity. However, a valid

and reliable method for evaluating dental programs is required. The Lost Permanent Tooth Index is suggested for this purpose.

LOST PERMANENT TOOTH INDEX

HOW IS IT OBTAINED?

The teeth of 12-14 year old children are examined by a dentist. This age group is selected because 28 permanent teeth should be in place, that is, all but the 4 third-permanent molars or "wisdom" teeth. Then, too, 7th and 8th grade conditions indicate the results of more than 6 years of service and/or instruction.

Two items are observed and charted: (1) Permanent teeth requiring extraction, (2) Permanent teeth previously extracted. Both constitute what may be termed "lost permanent teeth."

By using the compiling chart (Figure II) it is possible to obtain:

1. *The number of lost permanent teeth per 100 children*—By lost permanent teeth is meant the total of both permanent teeth requiring extraction and previously extracted permanent teeth.
2. *The percentage of children with lost permanent teeth*—That is, the percentage of children having permanent teeth requiring extraction and or previously extracted permanent teeth.

It may be noted that this Index does not evaluate dental programs for

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

preschool children. The author is preparing a Lost Deciduous Molar Index for this purpose.

Is the suggested method of evaluating dental programs practical, valid, and reliable?

little time (1 minute or less per pupil) consumed in obtaining the data for this Index would seem to indicate that this method of evaluating dental programs is practical.

PRACTICABILITY

The simplicity of the technic and the

"The retention of the permanent teeth, sound and healthy, functioning adequately and with comfort"¹ as an objective of dental programs.

Inasmuch as this Index shows the number of lost permanent teeth and indicates to what extent the permanent teeth are being retained in sound vital condition, it does measure dental health in accordance with a standard set by an authoritative body.

that this Index does measure dental health conditions:

1. It was noted that the children in communities of less than 5,000 population had lost fewer permanent teeth than did children in the more populated communities.
2. Negro children had fewer lost permanent teeth than white children.
3. Other conditions being similar, children in communities with well planned dental programs showed fewer lost permanent teeth than those in communities without programs.
4. Children in communities of high eco-

FIGURE III

How the Lost Permanent Tooth Index Enables One to Compare Contemporary Programs

Town A	Date—October, 1937	Town B
70%	7th and 8th grade children with lost permanent teeth	50%
150	Number of lost permanent teeth per 100 children—7th and 8th grades	170

FIGURE IV

How the Lost Permanent Tooth Index Enables One to Measure Progress Attained by Dental Programs

March, 1932	7th and 8th grade children with lost permanent teeth	55%
March, 1936	7th and 8th grade children with lost permanent teeth	40%
March, 1932	Number of lost permanent teeth per 100 children—7th and 8th grades	140
March, 1936	Number of lost permanent teeth per 100 children—7th and 8th grades	90

Figure III shows how the Lost Permanent Tooth Index may be used to compare contemporary programs.

Figure IV indicates how it may be used to measure progress within a community.

The following conclusions, arrived at by studying the Lost Permanent Tooth Index of 650 communities as obtained from the U. S. Public Health Dental Survey of School Children,² indicate

nomic level had fewer lost permanent teeth than children in poorer communities.

See Figure V for data.

RELIABILITY

The reliability of this Index was tested by having a number of dentists examine the same children. Uniformity ranged from 85 to 95 per cent.³ evidence of satisfactory reliability.

¹ See Dental Statistics, p. 234.

FIGURE V

1. AVERAGES ACCORDING TO SIZE OF COMMUNITY

Population	Lost Permanent Teeth per 100 Children
100,000 and over	80.8
25,000-99,999	90.2
10,000-24,999	70.0
5,000-9,999	75.8
Under 5,000	54.6

2. COMPARISON OF NUMBER OF LOST PERMANENT TEETH AMONG WHITE AND NEGRO CHILDREN

	Lost Permanent Teeth per 100 White Children	Lost Permanent Teeth per 100 Negro Children
In 22 cities	51.4	36.6

3. COMPARISON OF NUMBER OF LOST PERMANENT TEETH AMONG CHILDREN IN COMMUNITIES HAVING DENTAL PROGRAMS AND AMONG CHILDREN IN COMMUNITIES NOT HAVING DENTAL PROGRAMS

Communities With Dental Programs

	Lost Permanent Teeth per 100 Children
Pontiac, Mich.	19.3
Atlanta, Ga.	26.5
Des Moines, Ia.	41.3

Guggenheim Clinic (New York) Report

	Lost Permanent Teeth per 100 Children
Children entering service early with regular treatment	36
Children obtaining late dental care (10 years or over)	105

Communities Without Dental Programs or With Inadequate Programs

	Lost Permanent Teeth per 100 Children
Camden, N. J.	142
Lyndhurst, N. J.	199
Pittsburgh, Pa.	138.6

4. COMPARISON OF NUMBER OF LOST PERMANENT TEETH AMONG CHILDREN IN COMMUNITIES OF HIGH ECONOMIC LEVEL AND AMONG CHILDREN IN COMMUNITIES OF LOW ECONOMIC LEVEL

High Economic Level	Lost Permanent Teeth per 100 Children
Englewood, N. J.	73
Westfield, N. J.	49
Palo Alto, Calif.	11

Low Economic Level	Lost Permanent Teeth per 100 Children
Rahway, N. J.	168
Hoboken, N. J.	156
Garfield, N. J.	169

Note: Above data applied to children 12-14 years.

ATTAINABLE STANDARDS

The question is frequently asked:
"What may be considered attainable

standards?" Tentatively, it is suggested that attainable standards among white children be set in accordance with economic status. We may reasonably expect that the number of lost permanent teeth per 100 white children of 12-14 years would be:

For Economic Level	Lost Permanent Teeth per 100 Children (12-14 Yrs.)
\$5,000 and up	0-19
\$2,000-\$5,000	20-49
Below \$2,000	50-70

These suggested attainable standards merit conditional acceptance for the purpose of further study and analysis.

The author believes that, including all of the following will, in 5 years, effect results indicated by the suggested attainable standards: (1) educational programs to improve nutritional and dental practices, (2) repetitive dental inspections by dentists using mouth mirror and explorer plus follow-up guidance programs, and (3) preventive dental service programs for underprivileged children with emphasis on pre-school and lower elementary grade children, and treatment provided for older children as well. *Dental service programs based on emergency treatments will not reduce the number of lost permanent teeth.*

Summarizing, the adoption of the National Dental Inspection Chart for School Children will aid all communities to determine dental needs among children with greater uniformity. The use of the Lost Permanent Tooth Index is recommended as a reliable, valid, and practical means of evaluating dental programs among school children.

PUBLIC HEALTH NURSING DEGREES AND CERTIFICATES
GRANTED 1936-1937

In the Academic Year 1936-1937 there were 2,408 graduate students and 58 undergraduate students registered in public health nursing courses approved by the National Organization for Public Health Nursing. In the summer session or the 4th quarter of 1937 there were 1,040 graduate students and 3 undergraduate students enrolled. The following table indicates the number of students who received degrees and certificates in Public Health Nursing for this period. These figures have been supplied by the National Organization for Public Health Nursing and are printed here with permission. NOTE: No report received from Simmons College.

TABLE VI

<i>Course</i>	<i>Certificates</i>	<i>B.S. or B.A. Degree</i>	<i>M.S. or M.A. Degree</i>
University of California Division of Nursing Education	47	53	0
Catholic University of America School of Nursing	5	3	0
University of Michigan Division of Hygiene and Public Health	13	12	2
Wayne University Nursing Education Department	51	5	0
University of Minnesota Department of Preventive Medicine and Public Health	34	18	0
Teachers College, Columbia University Department of Nursing Education	0	38	10
Fordham University Social Service Department	3	0	0
Syracuse University Department of Public Health Nursing	9	2	0
Western Reserve University School of Applied Social Sciences	52	18	3
University of Oregon Medical School Department of Nursing Education	11	6	0
University of Pennsylvania Department of Nursing Education	9	3	0
George Peabody College for Teachers Nursing Education Department	32	15	2
Vanderbilt University School of Nursing	16	4	0
College of William and Mary, Richmond Division School of Social Work and Public Health	27	3	0
Medical College of Virginia St. Philip School of Nursing	4	0	0
University of Washington School of Nursing Education	35	27	1
University of Hawaii School of Applied Science	13	0	0
Total	361	207	18

For the school year 1936-1937 the total course registration was reported as 3,509 as compared with 3,353 in 1935-1936, an increase of 156 students. The number who received certificates or who completed the full public health nursing program in the school year 1936-1937 or who received degrees was 586 as compared with 445 in 1935-1936, an increase of 141.

WESTERN BRANCH, AMERICAN PUBLIC HEALTH ASSOCIATION

NINTH ANNUAL MEETING PORTLAND, OREGON

THE Western Branch celebrated its tenth birthday in Portland, Ore., June 6-8, the city in which it was organized on June 18, 1928. Dr. Frederick D. Stricker, long-time State Health Officer of Oregon, who made the motion to form a permanent Western Branch of the A.P.H.A., ten years ago, was made President-Elect.

The meeting was welcomed by the Mayor of the city, the Honorable Joseph K. Carson. Unfortunately the Governor of Oregon was detained. The President, Dr. P. W. Covington, opened the meeting with a historical sketch, after which the regular program was taken up.

The program throughout was excellent, full of interest for every class of membership. Deserving of special mention was the discussion "Progress in Public Health Under Title VI of the Social Security Program," by Assistant Surgeon-General C. E. Waller. This gave, for the first time that we know of, many facts in which all public health workers are interested. Other high lights of interest included a discussion of syphilis control, therapy, and laboratory aids; a panel discussion of public health nursing functions; a symposium on school and college hygiene; newer developments in plague distribution, dissemination, and control; and a discussion of tourist camp sanitation.

There were several sections, among which the laboratory workers deserve particular mention. This section had the largest attendance on record. Every state in the Western Branch and the Province of British Columbia were represented. Notable among the papers were "Developments in the Slide Test for the Diagnosis of Syphilis" and "The Culture of the Gonococcus."

The registration at the meeting approximated 550. The attendance was also the greatest of any meeting since this organization was formed. The membership of the Western Branch is now more than 1,300, of whom 801 are Fellows or active members of the parent Association.

This meeting saw the election of an unusual number of new members, since Dr. Fred T. Foard, Surgeon, U. S. Public Health Service, conducted an aggressive campaign for members throughout the Western Branch territory, and from his own pocket offered a \$25 cash prize for the state health officer who obtained the largest number of applications between January 1 and June 6, 1938.

An honor scroll was provided by Dr. P. W. Covington, the President, to be awarded to the state health officer who obtained the largest number of applications for membership in relation to population. This scroll is to be engraved with the name of the state health department winning it, to remain in its possession until it is awarded on the same basis again to the same state or to some other. This plaque is the property of the Western Branch, and is named in honor of its donor "The Platt W. Covington Honor Scroll." Both of these were awarded to Dr. J. L. Jones, State Health Officer of Utah.

A number of other organizations met at the same time and in the same hotel, and shared in the meetings of the Western Branch. Among these were the Conference of State Supervisory Nurses, Conference of City and County Health Officers of Oregon, Washington State Public Health Association, Oregon Nutrition Council, Northwest Association of Milk Inspectors, and the Oregon Milk Inspectors' Association.

The exhibits, both commercial and scientific, were excellent. Perhaps those of the Los Angeles City Board of Health on "Rabies" and that by the Montana Rocky Mountain Spotted Fever Laboratory at Helena, Mont., deserve special mention. In the latter were unquestionably the best exhibits of ticks concerned in the transmission of spotted fever which are in existence. It was also illustrated by the most beautifully done drawings.

The annual banquet took place on Tuesday evening, and was attended by more than 400. A most unusual, but none the less welcome and honored guest, was Darigold Periwinkle, owned by Mr. and Mrs. M. C. Fleming of Portland, who is the World Champion Golden Guernsey. Perhaps her presence had something to do with the meetings of the Northwestern and Oregon Milk Inspectors' Associations and the fact that the dairying industry in the Northwest is going ahead by leaps and bounds. In the general discussions, the sanitation of milk production and pasteurization were well to the fore.

Toward the end of the banquet Dr. Guy S. Millberry, President-Elect, succeeded Dr. Platt W. Covington as President for the ensuing year.

It was especially pleasant to see the large number of Canadian visitors, headed by the honored Dean of health officers, Dr. Henry E. Young of Victoria.

The hospitality of Portland is famous, and those in attendance who had not experienced it before were fully convinced that none of the reports of it which had reached them had been exaggerated. Entertainments, especially for the ladies, were provided in abundance, including drives and trips to some of the most interesting places within a hundred miles of Portland. We need hardly call attention to the fact that Portland is famous for its beautiful location, the two grand mountains that are in full view of it, and many other points of interest as well as beauty. All who were fortunate enough to attend this meeting will look forward to the first opportunity again to visit Portland, the City of Roses.

Other officers elected in addition to Dr. Stricker were: *Vice-Presidents*, Dr. J. D. Dunshee, Director, Local Health Administration, State Board of Health, Phoenix, Ariz.; E. H. Bramhall, Director of Laboratories, State Board of Health,

Salt Lake City, Utah; Anna L. Heisler, Supervising Nurse, U. S. Public Health Service, San Francisco; *Secretary*—Dr. W. P. Shepard, Metropolitan Life Insurance Company, San Francisco, Calif.; *Treasurer*—W. Ford Higby, Executive Secretary, California Tuberculosis Association, San Francisco. New Regional Board members elected were: Dr. R. L. Cleere, State Health Officer, Denver, Colo.; Dr. E. B. Godfrey, State Health Officer, Santa Fe, N. M.; Dr. A. U. Simpson, Director of Laboratories, State Department of Health, Seattle, Wash.; Elizabeth Soule, Director of Public Health Nursing, University of Washington, Seattle, Wash.; Dr. Helen A. Cary, Medical Director, Division of School Hygiene, Bureau of Health, Portland, Ore.

The next meeting will be in the San Francisco Bay Region in May or June, 1939.

ESTIMATES OF NUTRITIONAL STATUS

OF recent years communities have shown an increasing interest and participation in programs for the improvement of the nutritional status of their children. Frequently a considerable portion of the public health budget is expended for this purpose. In such programs, the routine examination of groups of children by a physician to identify the malnourished ones and give them special consideration is a commonly accepted procedure. Yet a recent paper in the *Public Health Reports* indicates that such an activity may not be as effective as it was previously considered. This conclusion is based upon the finding that there are wide disagreements in the nutritional estimates of the same children by different physicians. For example: It was shown that out of 108 boys examined by 6 physicians, 25 were judged malnourished by at least one of the physicians, yet only one child was so considered by every examiner. In a second sample of 113 girls examined by a second group of 6 doctors, 65 were judged to be malnourished by at least one physician and only 4 were so considered by all 6 of them. These disagreements are summarized in the statement that "the rating of nutritional status which any child is given depends to a large extent on which doctor makes the rating."

The practical significance of these findings so far as individual children are concerned is pointed out in the following illustration. If Dr. A had been a regular school physician and had examined the 113 girls, she would have indicated that 32 of them needed special attention to improve their nutritional condition. If Dr. B had been the school physician, she, likewise, would have indicated that 32 of the girls needed special service. But only 17 of those judged malnourished by Dr. A were so considered by Dr. B. Each doctor selected 15 as malnourished that were considered normal by the other physician. These data indicate the futility of nutritional programs that give special attention to a few cases regarded as deficient in nutritional status on the basis of a routine physical examination. The errors in the doctor's estimates are too great to justify the extra effort given to the individuals chosen.

It is also pointed out that the use of such judgments to determine the prevalence of malnutrition at any one time or to measure changes in the prevalence over a period of time is apt to be misleading. Wide differences in the incidence of malnutrition may arise because of the variation in the judgments

of the doctors. For example, one physician found 7 times as many malnourished children in the group of boys as did a second physician.

The findings of this paper are not altogether new to physicians. They have always known that their judgments were not infallible. Even under the best of conditions where a clinical history and some information on the hereditary background of the child may be obtained, a pronouncement on his nutritional status is difficult. Despite this difficulty the best advice a mother can obtain on an individual child is that given by a physician after he has had sufficient time to examine and study the child. But under the less favorable conditions of a rapid routine examination, such as is usually given in schools or on surveys, the difficulties of accurate nutritional estimates are practically insurmountable and such disagreements are likely to occur.

As a substitute for programs based on rendering service to a few children specially selected on such unreliable estimates, it is suggested that attention be focused on the discovery of those individuals who have faulty food habits, or whose behavior symptoms such as failure to gain in weight, lack of stamina, and lassitude, suggest the need for medical advice. Thus the interest would be in preventing the occurrence of malnutrition as well as correcting it after it occurs.

It is also suggested that research workers concentrate on the construction of valid methods of determining nutritional status rather than making surveys which are of doubtful significance because of the inaccuracies of the estimates upon which their findings are based.

Though there is no evidence to show that these two suggestions are the proper procedures, yet they would seem to warrant experimental trial by those responsible for nutritional programs.

THE DEAD HAND OF AUTHORITY

MANY years ago, Oliver Wendell Holmes said he had learned three things in Paris: "Not to take authority when I can have facts, not to guess when I can know, and not to think a man must take physic because he is sick." Holmes had been under the influence of the New School of Medicine in Paris, of which Louis was the founder and great representative. Louis abandoned a lucrative practice and "gave nearly 7 years, including the flower of his bodily and mental powers . . . to vigorous, impartial observation." Everyone who thinks, and perhaps especially everyone who writes, knows that the lesson learned by Holmes and passed on by him still needs to be emphasized. No one can deny the great debt which we owe to the Fathers and no one would detract one jot or little from their credit, for "it is a sign of a dry age when the great men of the past are held in light esteem." Nevertheless, too many of us are bound by the dead hand of authority.

Religious authority for centuries stood in the way of the advances of medicine. Within the time of practically every reader of this *Journal* authority has denied certain great scientific truths and hindered progress in biology and medicine. The general subject has recently been reviewed in a masterly address,¹ in which

are recalled some outstanding examples of the influence of the dead hand of authority over advance in the medical sciences. We remember the interdictions against the dissection of the human body and the long delay in the most rudimentary knowledge of the body which resulted. Harvey, the discoverer of the circulation of the blood, had to leave Cambridge and go to Padua, but it is said that even he in his later life came more or less under the influence of authoritarian thought. John Mayow (1645-1649) made discoveries concerning what we now call oxygen and its rôle in respiration which would have been revolutionary if carried to their legitimate conclusions. He showed that blue venous blood became red by the absorption of something which he called the "igneo-aerial" particles of the air. Joseph Priestly (1771) made accurate experiments but did not draw correct conclusions owing to the influence of the dead hand. The influence of Stahl (1737), with his doctrine of animism, which was a revamping of vanHelmont's "sensitive soul" as a source of all vital phenomena, is said to have blocked progress in the chemical aspects of physiology throughout the 18th century. It was only when Lavoisier (1775) announced his discoveries that the atmosphere was cleared and many observations "fell into their place, as at the touch of a magician's wand."

It seems to many people that authority still plays too great a part in the ordinary medical education. Much of this is probably due to lack of preparatory education and to the greater or less amount of mysticism with which the ordinary mind endows anything pertaining to medicine. It is true that some professors, unfortunately too few, have the power of developing originality in their students and of inspiring in them a desire for research, but to a great extent this curiosity to unearth basic facts is born and not made, though it can be fostered. There is no doubt that the average teacher could do more than he does to cultivate an open mind controlled by critical judgment. Sir Walter Langdon-Brown holds, correctly we believe, that in spite of the faults which exist in our present system of medical education "every medical school is a guardian for the future of truth." The views of Sir Walter have brought forward other considerations. The writing of textbooks by young and inexperienced men brings about the "perpetuation of accepted views which have not been redissolved and recrystallised from experience."² Bad as this is in medicine, it is probably worse, or more frequent, in hygiene and preventive medicine. The market is flooded with such efforts, many of which add nothing to knowledge, and do not even present facts as well as the texts from which they are taken.

What shall we say about preventive medicine? Do not the same conditions apply? We believe so, but to a lesser extent, since public health as we understand it today, is a new development. It is true that the ancient Greeks developed personal hygiene to a high degree and that the Romans were well advanced in public sanitation in the way of baths, abundant water supplies, sewerage, disposal of refuse, and things of that nature, as early as 494 B.C. All of these things passed in the Dark Ages except the control of epidemics. It is also true that the Jewish code of hygiene, as found in Leviticus, was the earliest known and even today is recognized as sound. While isolated studies such as that of the Broad Street Pump epidemic in London (1854) taught sound lessons, the birth of modern preventive medicine may be dated from the researches of Pasteur. In spite of all that bacteriology has done for medicine

and preventive medicine, it seems to have overshadowed some important matters, and in a way has delayed the recognition of the importance of other factors in public health. The deficiency diseases, for example, were perhaps not recognized as early as they might have been. In spite of the progress on which we have good reason to congratulate ourselves, there are still subjects of great importance which are knocking at the door of public health,³ among which mental hygiene, psychology and psychotherapy are the newest and most prominent applicants. The place of mental hygiene is fairly well established and a recent writer holds that there is even an epidemiology for it.

A CONTRAST

RELIGION and medicine have often found themselves in conflict, especially as to certain rites and observances. The pilgrimages of India are notable in this respect, have cost tens of thousands of lives, and have been the means of spreading cholera over large areas. The number of pilgrims is estimated at 20 million annually.¹ One can imagine nothing more ghastly than the reports of some of these only a few years ago. The sacred Ganges, which is 1,600 miles long, is bathed in as a religious duty by millions, made up not only of those living near its banks, but of pilgrims, and the dead are cast into its waters. Sickening accounts have been written by Hunter, the Bishop of Calcutta, and by Bishop Wilson, among others. At the feast of Juggernaut, the Temple kitchen has the monopoly of cooking for the multitudes. The food cooked there is too sacred for any of it to be thrown away. It undergoes putrefactive fermentation, and within 48 hours is a loathsome mass unfit for human food, yet it forms the chief nourishment for thousands. The housing could not be worse. As many as 80 persons pass the night in lodgings 13 feet long, 10 feet broad, and 6½ feet high. The stench is said to be overpowering, and as many as 90,000 people are packed together for a week in 5,000 of these lodgings. Bishop Wilson estimates the slaughter of one pilgrimage at 50,000, and says that the description given of one might well be used for all the great pilgrimages—at least a dozen. Hunter states that 24 high festivals take place annually at Juggernaut. From the accounts it is not surprising that Bishop Wilson has said that Hindostan "well deserves the reputation it universally possesses of being the birthplace and settled home of the malady."²

The contrast showing the introduction of modern medicine is so great as almost to pass belief.³ Since the whole world is interested in preventing the spread of Asiatic cholera, the Egyptian Maritime and Quarantine Sanitary Council has for 10 years made an annual report to the Permanent Committee of International Public Health at Paris as well as to the health authorities of all the countries interested in the pilgrimages to Medina and Mecca. This festival attracts some 100,000 worshippers. For 1936 the general health was satisfactory and there was an entire absence of infectious diseases. The absence of intestinal trouble is accounted for by the cooler weather. It is particularly interesting to note that this year, 105 people came by aeroplane, and it is

reported that there are indications that this mode of transportation will become more popular.

All of the pilgrims had to submit to vaccination against smallpox and double inoculation against cholera and typhoid fever. The countries of origin have been studied by the Regional Bureau of Sanitary Inspection for the Near East, and so have warnings of any sources of infection. There is coöperation in the carrying out of sanitary measures so that a pilgrim cannot obtain a passport unless he has a medical certificate from recognized authorities stating that he is free of disease. Ships carrying pilgrims are rigorously inspected and a report must be made on the structure of the vessel, accommodation, food, water supply, sanitation, and deratization. No pilgrims are allowed to supply their own food. Food is well prepared by the authorities and must be eaten under sanitary conditions. The camps have electric lighting, incineration, disinfectors, clean kitchens, and clean bedding. At Tor, 16,700 pilgrims were inspected, and examinations of blood, stools, and sputum of all suspected cases made.

This report applies only to the pilgrimage of Hedjaz, which is one of the most important, since it "has, for the last 81 years, been the post of relay of cholera in the rate of progress from the Far East towards the West."⁴

PUBLIC HEALTH EDUCATION*

Education in a Cancer Program—

One of the 5 main elements in the Massachusetts Cancer Program is education. Paragraphs describing the education phase of the program are taken from a talk by Eleanor J. Macdonald, epidemiologist of the State Department of Health. This talk was one of the many in which the state program is presented for local application.

In 1936 an order to disseminate knowledge concerning cancer did not suggest as precise a plan of action as a similar order would today. Every possible means of disseminating knowledge was immediately used. The radio, newspapers, and pamphlet distribution were all employed. There were large meetings held at central points to which famous authorities were invited to speak. These meetings were attended by hundreds of people who seemed to be enthusiastic. Although these general educational measures have certain intangible traits in common which make it difficult to measure their effectiveness, it was determined that some method of measuring the effect of these time-consuming educational projects must be evolved. At first, visits were made to physicians' offices in the territory surrounding the location used for one of the large meetings. The physicians were asked if there had been an influx of patients, especially of cancer patients, following one of these lectures, and if they thought that individuals were inspired by what they had heard to take some action. It was found by this means of evaluation that only the briefest flurry of interest was aroused by these meetings which took so much effort.

A second means of evaluating the effect of education became available with the passage of time. This was in the form of information that could be obtained from the cancer clinic records. After 8 years there were enough of these records to form a fair sample on which to base a sound study of the cancer educational situation in Massachusetts. Since

cancer, to be controlled, must be treated early, the most important measurement figure to watch is the average period of time that an individual waits after he knows that he has an abnormal symptom before he seeks medical advice. There is another figure that is very important from an educational point of view and that is the average length of time that individuals wait after they have been diagnosed by a physician before they put the recommended treatment into effect. It was found by this study; first, that there was not one individual who did not know he had symptoms of an abnormal nature for a considerable length of time before he sought attention; second, that the time individuals waited from the first appearance of this abnormal symptom until they sought medical attention had not been cut down by a fraction of a month and still averaged more than 6 months; third, that the period of time that individuals waited to put the prescribed treatment into effect after they were diagnosed by a physician was cut in half.

The one redeeming feature of this study indicated that the most promising way to control cancer in Massachusetts was through the family physician. So after the 8 years of usual methods of education, it was deemed wise to introduce a personal type of cancer education. Every individual would have to be given a chance to know exactly what was known and exactly what was not known about this disease. This exact knowledge precisely presented would give confidence which would in turn awaken realization of the need for prompt action.

In 1934, the Division of Adult Hygiene of the Massachusetts Department of Public Health began to organize every one of the more than 350 communities in Massachusetts into Coöperative Cancer Control Committees. Each community is studied first as an individual problem. The census figures reveal the various age groups, the various national groups, and the general population structure. The town directories list the clubs, churches, businesses, and industries. With this material thoroughly understood before the first contact is made, the original individual approaches the community with a fair idea of the size of the problem.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

The surveyor contacts the board of health and in various ways finds out who the representative citizens in the community are. He has a meeting with these individuals, explains the plan in brief, and seeks advice as to what other individuals have the friendliest contacts in their own groups. Racial, social, fraternal, religious, labor, service, and all groups in the community are represented. The surveyor then has assistants to visit personally all these representatives. Their cooperation is sought, the plan is explained to them briefly, and they are asked to come to a formal organization gathering such as this meeting.

Assembled as we are here to determine how we may best face this problem together, we will again go into this plan. We want each one of you to go back to the group that you represent to ask them to have at least one meeting a year at which cancer is discussed and to which a local physician is invited to speak. The nature of the group determines the type of a talk. Some groups prefer a formal speech and others ask a physician to come in and answer questions. Whichever type of meeting your organization prefers is for them to decide, but in every case plan to have a question period. Do not feel that any question that any individual one of you wishes to ask will be taken lightly or will seem absurd. It has really been felt that the failure of large group meetings to accomplish their end is because their size precludes any possibility of a question period. It is through this question period that the greatest hope lies for controlling cancer. Every community has many of the same ideas. Each community usually has an idea peculiar to itself—"Does aluminum cause cancer?" "Do tomatoes cause cancer?" "Are there cancer streets?" "Is cancer contagious?" "Is it hereditary?" These are some of the questions that every community asks.

Some individuals have wondered what difference it made whether a person thought for example that tomatoes caused cancer. Individuals with cancer have often come to a physician's attention who had delayed beyond the hopeful stage because they thought tomatoes caused cancer and they had abstained from eating tomatoes. While they took an erroneous precaution they had been blind to the possibility of cancer developing in their case. This is one outstanding example, of which there are many, where true and false knowledge has made a difference between life and death.

This community is not being approached

while this plan is in the experimental phase. . . . Two hundred sixty communities have been organized. Many of the others are in the process of being organized. The meetings that have been held in this connection within the last 3 years have numbered thousands. There are approximately 4,000 individual committee members who keep in contact with the department all the time on this subject. The number of meetings being held each year varies all the way from more than 250 in Cambridge to the 3, representing the whole community, in Monroe Bridge.

In many places these small groups have their meetings, notify the central committee, who in turn notifies the department of public health without any prompting from the central committee. Other communities find that the individuals representing certain parts of the population have to make an occasional visit or call to the clubs in those groups to make sure that a meeting is held. Printed post cards with spaces to fill in the following information—the name of the club, the date of the meeting, the number present, the physician speaking, and any remarks which the group thinks would be of interest in the main office, have been placed with this committee. . . .

After every community in the state is organized, we are going to start all over again and see if we can reach those individuals who might have been missed in the first organization because they were not affiliated with any club or any group. . . .

The Income of the Audience—Family income, of course, affects much more than the status of medical care. It sets many factors which have to do with the acceptance and application of health instruction.

These paragraphs merely direct attention to the 3 year study of how American *native born* families make their living and spend their money. The study has been made by the Bureau of Labor Statistics, Dept. of Labor, and Bureau of Home Economics, Dept. of Agriculture, in 51 cities, 140 villages, and 64 farm counties. Some 285,000 families figure in the final returns.

Several pages of charts accompany an explanation of the study as reported in *Business Week*, 330 W. 42d St., New York, N. Y. April 9, 1938. 20 cents.

A "family" consisted of at least a husband and wife . . . who had been married at least a year . . . are living in housekeeping quarters . . . and were both born in the United States. The status of the foreign born was left for another study.

Of the families studied in cities of 200,000 to 300,000 population: 27.6 per cent were on relief or had less than \$1,000 annual income; 39.3 per cent between \$1,000 and \$2,000 income; 23.7 per cent between \$2,000 and \$3,000; 14.9 per cent had \$3,000 and over.

Of the families in cities of 30,000 to 70,000 the proportions were: 35.4 per cent under \$1,000; 39.8 per cent, \$1,000 to \$2,000; 16.2 per cent, \$2,000 to \$3,000; 8.6 per cent, \$3,000 and over.

These samples will suggest the significance of one phase of the study which was made primarily for use by business executives in laying out merchandizing plans.

The Uncounted Radio Audience— Much is said about the measurable radio audience. Broadcasting companies, research organizations, and radio followers submit a mass of more or less convincing data.

But *Business Week* (May 28, 1938) reviews the differences between the commonly accepted Crossley and Hooper reports, and the further differences by test check-ups made by a few advertisers.

B.W. quotes a leading commercial advertising director:

"We have not at the present time discovered the ideal method for gauging accurately what we buy when we buy radio, so far as circulation is concerned."

Business Week, 330 W. 42d St., New York, N. Y. 20 cents.

To Quote and To Be Quoted— We have urged that quotable material appears in monthly bulletins and else-

where. In response one editor has asked for suggestions.

The main idea is to note good stuff as it appears in various bulletins and other publications, and to help give it a larger audience—and make it do a bigger job. This has been the policy of several editors of state and local bulletins.

The companion big idea is to write something of your own now and then that other editors will wish to quote for the benefit of their readers. Needless to say, permission should be asked and credit given in every case.

"Where They Can Learn"— Under this heading *Business Week* (May 28, 1938) editorializes on the subject of public relations for business and industry. "Where they can learn" would be "a seminar or study group of not more than 15 or 20 searchers."

Public relations for health agencies calls for a similar approach. Health education on behalf of the organizations, as well as education in health practices of individuals and families could be furthered by such a group—or several groups.

The most experienced among us could jointly tackle some of the many perplexing problems. The experienced ones would be all the better equipped through such a procedure. The less experienced should be helped far beyond the expectations of pessimistic executives.

Not a 3 day institute with a crowded program, and competing distractions can serve the purpose. But a full week quite apart from any convention, and preferably away from a "big city." A week would be a modest minimum. A month would be all the better. However, several one week tests would show the way such a group might go.

Will executives and practitioners alike comment on this suggestion?

SPECIAL EDITIONS

The first of the new crop of newspaper health magazine supplements comes from New Haven, Conn. The "Better Health" edition of the *New Haven Sunday Register* is dated Feb. 27, 1938, and covers 36 pages. Among the features are a symbolic cover page; a page carrying facsimile letters from the Mayor of New Haven and the Governor of Connecticut, accompanied by portraits, and the Inter-Chamber City Health Conservation award to New Haven; the illustrated Diabetes Historical Landmarks (New York City Health Dept.); "Personal Health Aided by Books," by the Public Library readers' adviser; "Spider Web of Syphilis" (illustrated diagram); "The Medical Practitioners of Little Old New Haven" (sketches going back to 1645); "Old Time Nostrums Made It True, 'Cure Is Worse Than Kill'"; and so on. There are numerous illustrations, with some readable captions. For a copy send 10 cents to Paul H. Stevens, public information assistant, Health Department, New Haven.

Special health editions of Hertford County Herald and Jackson News of

Northampton are mentioned in North Carolina's state *Health Bulletin*. Local health officers participated in both cases.

Winston-Salem's *Journal and Sentinel* came out May 1, 1938, with a child welfare section of 8 standard pages. Numerous illustrations, nearly all being local scenes or subjects.

MAGAZINE ARTICLES

"Have They Died in Vain?" by H. Krieghbaum. *Survey Graphic*, 112 E. 19th St., New York, N. Y. May, 1938. 30 cents. Status of food and drug legislation. Letter from mother of a sulfanilamide victim as the appeal.

"Leaves from a Surgeon's Casebook," by James Harpole. (Stokes, New York). Condensed in *Book Digest*, 350 E. 22d St., Chicago, Ill. May, 1938. 25 cents. Records "the rapid progress which medical and surgical science has made."

"Medical Superstitions," by Dr. Morris Fishbein (a page of pictures); "150,000 Childbirth Tragedies" and what government is doing about it (4 picture pages). *Look*, Des Moines, Iowa. May 10, 1938. 10 cents. More nation-wide health education.

BOOKS AND REPORTS

Lectures on the Control of Syphilis and Other Infectious Diseases—
By Thorvald Madsen, M.D. Baltimore, Md.: Williams & Wilkins, 1937.
 216 pp. Price, \$3.00.

Dr. Madsen's book consists of 5 lectures given as the Abraham Flexner series for 1937 at Vanderbilt University. The series includes addresses on widely diversified subjects, and reflects the broad range of the author's learning and experience.

The first lecture deals with venereal disease control in Denmark, a topic already somewhat familiar to public health workers in this country. Treatment for syphilis by compulsion began in the 18th century in certain parts of Denmark and at its inception was strongly opposed. Later the public began to understand and with the co-operation of the clergy the necessity for syphilis treatment became recognized and accepted. Dr. Madsen believes that the underlying factor in the relatively satisfactory condition in Denmark as far as venereal diseases are concerned is expedient and adequate legislation that gives easy access to free treatment. The present excellent facilities for diagnosing and treating syphilis at public expense are described. The reproduction of the serological test record of a Danish patient will be of special interest to those engaged in syphilis control.

The "Mechanism of Bacterial Infection" is the subject of the second lecture. Numerous experiments at the Danish State Serum Institute are reviewed, most of them involving the administration of organisms of the salmonella group to animals and tracing the course of the bacteria administered

by means of pathological and bacteriological examinations at stated intervals after the initial dose. Besides organisms of the salmonella group, *B. abortus* and the tubercle bacillus were used. The studies make it appear that when organisms are given by mouth the route of infection is always the same. Direct infection of the blood stream from the intestinal tract has never been demonstrated. Organisms pass from the intestinal tract to the regional lymph glands, and thence through the lymphatics to the thoracic duct, and to certain organs, particularly the liver and spleen. Organisms reach the blood stream through lymphatic channels, and in many infections the presence or absence of bacteremia seems to depend upon phagocytosis, especially in the liver and spleen, rather than upon any bactericidal powers of the blood.

According to Dr. Madsen's third lecture, the cost can never keep a tuberculosis patient in Denmark from being treated properly. There are two sanatorium beds for each annual death, adequate diagnostic facilities, and facilities for extramural X-ray and pneumothorax services. Americans who realize the social and economic implications of tuberculosis will appreciate the provisions of Denmark Social Care Acts. These laws provide for giving needy tuberculosis patients and their families full maintenance during the first 3 months after the discharge of the patient from a sanatorium.

Dr. Madsen gives the results of tuberculin testing in various localities, and of experimental studies of the same nature. There are many authorities who would not agree with his statement that "it seems an established fact that,

except cases of a quite new infection, the tuberculin-positive are better protected against subsequent infections than the tuberculin negative." Also, many health officials may question Dr. Madsen's belief that there are good reasons for advocating vaccination by the Calmette-Guerin method.

"All born in northern climates can speak of the effects of the yearly change on our condition and from antiquity months of the year have been associated with diseases." Dr. Madsen in this fashion takes cognizance of common experience in his lecture on the influence of seasons on infection. He then cites numerous examples of seasonal distributions of disease. Taken for the most part from the unusually complete Danish morbidity records, these examples are striking in that they include seasonal distributions for such diseases as gastric ulcer, impetigo, erythema multiforme, and other conditions for which occurrence by months is seldom recorded. Dr. Madsen reviews experimental observations on the possible relationship of light, vitamin deficiency and other factors to seasonal distribution, and closes his lecture with emphasizing the fact that the health officer must be familiar with seasonal fluctuations in his own community. He must also determine the cause of an unusual rise of any disease out of season.

The last lecture is on whooping cough. Statistical data from several countries are presented to show that whooping cough is one of the most fatal of the acute infections of children. In spite of this, it is assuring that the trend of mortality has been downward over a period of years in most countries. As shown by data from many localities, the proportion of older children surveyed who give histories of whooping cough is very large. The disease causes much loss in absence from school and may be followed by physical

and psychic troubles of long duration.

Dr. Madsen accepts Bordet-Gengou bacillus as the cause of whooping cough, and states that facilities for diagnosis by the cough plate method have been established at the Serum Institute. On the basis of frequent cultures during illness, it has been found that organisms are few by the 4th week after the first paroxysm, and it is considered safe to readmit children to school on this basis. During experiments with whooping cough vaccine on the Faroe Islands, the mortality in the vaccinated group was one-sixteenth that of the unvaccinated, and cases among the vaccinated were mild and of short duration. Whether these results were due to specific immunity, or to nonspecific immunity lasting only a few weeks after injection was not decided.

GEORGE H. RAMSEY

Milk Control: Governmental Regulation of the Dairy Industry in the United States—*Prepared and published by the American Municipal Association. Chicago, 1937. 49 pp. Price, \$.75.*

The principal steps taken by federal, state, and local authorities to regulate this important industry for consumer protection are reviewed and the developments necessary further to purify milk in every section of the country are examined and explained. Four out of every five communities with population over 1,000 to 10,000 do not regulate the conditions of production or distribution of milk. Less than 40 per cent of the milk consumed in such communities is pasteurized and little or no attempt is being made to urge producers to pasteurize milk before they use it in their own homes. With bovine tuberculosis practically eliminated, Bang's disease in cattle (one of the causes of undulant or Malta fever) and mastitis (which causes the secretion of abnormal milk) still need to be brought

under control. More accurate reporting of milk-borne infections is needed. Under our system of state and local government, milk regulations naturally are not uniform throughout the United States, and this lack of uniformity continually offers reason to those who believe in efficient government from above to urge federal and state regulations. The general approach used in this review is one that supports federal and state control with consequent suppression of municipal and community initiative.

This pamphlet discusses in some detail the attempt to standardize regulations through the use of the model milk control ordinance which has been developed since 1923. It states that many communities have adopted the model ordinance, but does not point out the fact that this type of standardization may be carried out in such a way as to repress new developments. The review also fails to call attention to the fact that communities, e.g., New York City, that have efficient milk control based on other types of regulation do not receive recognition for their work in the published records issued by the federal authorities urging the model milk ordinance.

Little recognition is given in this pamphlet of the fact that the enforcement of any ordinance designed to control the quality of the dairy products should be based on a laboratory examination of the product whose quality is to be controlled as well as an inspection of the sources of supply and processing plants. Thus, there is only incidental mention of the report on *Standard Methods of Milk Analysis* which has been developed under the auspices of the American Public Health Association.

Nevertheless, the pamphlet issued by the American Municipal Association summarizes so much information of value that everyone interested in the

important question of the sanitary quality of our dairy products should have a copy. ROBERT S. BREED

Health Section Report, World Federation of Education Associations—*Seventh Biennial Conference, Tokyo, Japan, August, 1937. Available from the Health Section Secretariat, 200 Fifth Ave., New York, N. Y. Price, \$1.00.*

This report gives the proceedings of the conference held in Tokyo in August. Dr. C. E. Turner, Chairman of the Health Section, and Sally Lucas Jean, Secretary, planned a program to which representatives of 15 nations were welcomed. Present membership in the section consists of 200 groups in 26 countries. Health information is sent by regional correspondents to the secretary in New York. From here it is disseminated in answer to inquiries from other countries. Dr. Turner emphasizes the fact that the section is not interested in standardization, but in learning the best experience of all countries and helping its members to benefit therefrom.

The report is very interesting and readable. Perhaps its most important lesson for us is that there are "many ways to skin a cat" in public health work. It is well for us to bear this in mind since we are often inclined to be intolerant of others whose methods differ from our own but whose results eventually are as good. Discouraged rural public health workers in this country may take heart from reading the reports from Punjab and from Egypt. Self-satisfied health workers may find new worlds to conquer by reading the reports from Hawaii, the Philippines, and Japan. The Chinese delegate reports a number of inherent obstacles in his country, among them the fact that medical education in China has been taken from overseas and most teachers in medical schools

do not see the relation between education and keeping healthy. Where have we heard that before?

It is evident that the educational abilities of the public health nurse are being recognized and utilized in other countries as well as our own. With the exception of Japan, each country reporting speaks highly of her values. It is also evident that the United States is not unique in befogging the public health field with many activities only indirectly related to health. Thus, the papers contain discussions of gymnasias, sports, military training, morals, baby contests, community singing, religion, and philosophy. Many countries appear to be farther advanced in attention to teachers' health than this country. One searches through the report in vain for definite proof that the elementary school health program is resulting in lessening the incidence of physical defects among college students and those entering industry. The Junior Red Cross appears to be a potent influence in health matters in many countries.

Teacher training, physical education, special schools, the part of the physician, the nurse, and the teacher, the relationship of the home and school, sight protection, dental health education and service, and physical examination of college students are discussed at length. This volume should be of interest to public health and school personnel. It should inspire readers with a renewed desire to help improve the health of children whatever their nationality.

W. P. SHEPARD

The Foundations of Nutrition—

By Mary Swartz Rose (3rd ed.) New York: Macmillan, 1938. 625 pp. Price, \$3.50.

This is a welcome revision of a much used text in college courses in nutrition. The organization is fundamentally the same as in the earlier editions, but each

topic has been rewritten in the light of recent discoveries in the field, and all tables have been revised.

The subject matter is selected and presented for those who wish to gain a knowledge of the significance of food so that they may "live more intelligently." In the 26 chapters the author presents very simply and clearly some of the basic principles of human nutrition and makes practical application of these principles to the feeding of individuals or groups of individuals. Special attention is given to the discussion of dietary essentials—energy, protein, the ash constituents, vitamins, and water; of the contributions to the diet of various types of food materials; and of the construction of adequate diets. The appendix comprises 9 compact tables which include height-weight-age tables for children and adults; detailed information on the energy cost of activities; plans for constructing adequate diets for persons of various ages and conditions; and data on the nutritive value of food in terms of "shares." From these tables the nutritive value of any diet can be calculated easily.

The discussion of energy, including the need of the body for energy, the energy requirement of adults and children, the methods of measuring energy production, and the effects of a shortage or a surplus of calories, has been little changed. The results of recent researches have been incorporated in the discussion of proteins, vitamins, and minerals. Liberal use is made of photographs, tables, and charts to illustrate and emphasize the points under consideration.

Having presented the fundamental facts concerning the dietary essentials, the author points out the contributions of these factors made by the different foods. The foods are grouped on the basis of their similarity in nutritive properties. These groups serve as a

foundation for the planning of diets to meet the daily requirements. The construction of adequate diets for children of various ages, for adults of different occupational groups, for families on different income levels, and for the mother and baby are given careful consideration.

In its revision the book has lost nothing and has gained much that is of value. Subject matter, tables, dietaries, and references have been brought up to date and much new illustrative material has been added.

VIRGINIA BATIE WHITE

Standard Business Etiquette—By J. George Frederick. *New York: Business Bourse, 1937.* 188 pp. Price, \$1.75.

Executives and staff members are concerned with how to do things together—how to get things done through right personal relations. To that end we have this book presenting "personal codes for smooth-running organization efficiency."

There are chapters on being "business-like," on using the telephone, on conferences, and chapters for private secretaries, for reception clerks, and for executives and employers. Any one of these chapters makes the book worth the price to a health agency. They are practical and "business-like."

The book first claimed our interest through the chapter on the business conference, in view of many weary hours spent "in conference." Addressed to business groups, yet largely this chapter is applicable to health agencies. Studied and practised, these 14 pages would help to make staff conferences interesting, and actually an important factor in administration. And the 25 rules with comment should retrieve countless conference-hours now grimly endured without hope of fruitful results.

At least take a chance, and ask the publisher to send a copy on approval.

EVART G. ROUTZAHN

Dairy Bacteriology—By B. W. Hammer, B.S., M.S., Ph.D. (2nd ed.) *New York: Wiley, 1938.* 482 pp. Price, \$5.00.

The author is eminently qualified by experience, accomplishments, and insight to write a book on dairy bacteriology. In this revised edition the newer phases of dairy bacteriology have been incorporated and the book brought up to date in every respect. He again emphasizes the fermentations taking place in milk and its derivatives, since an understanding of these is essential not only to the student and the practical bacteriologist but to any one responsible for the quality of dairy products. Material selected from the leading dairy bacteriology departments in the country makes the book a source of valuable information.

Beginning with the fundamental chapters on bacterial determinations of milk and milk fermentations, there is a comprehensive and authoritative discussion which leaves in the mind of the reader a picture of the difficulties met with in the manufacture of dairy products of high quality. The basic facts underlying the practice of such production are clearly presented.

The chapters on contamination of milk and cream and its control, and the destruction of microorganisms are particularly well presented. The book is not a mass of theory on controversial subjects but of technical and practical knowledge usable by those responsible for the quality of milk and milk products.

The make-up and printing are excellent. The first edition at once took its place as a standard. This second edition maintains the high character of the original and the book will doubt-

less keep its place as one of the most authoritative and useful in its field.

R. G. McCARTY

Fit To Teach: A Study of the Health Problems of Teachers—*Ninth Year Book, Department of Classroom Teachers, National Education Association, Washington, D. C., 1938.* 276 pp. Paper. Price, \$1.00.

Here is a report, with interpretation and the application of the data, along with a health manual for the classroom teacher. The basic material is drawn from 5,000 questionnaires from classroom teachers, and several hundred from school physicians, superintendents, principals, and teachers' associations.

A chapter asking if teachers are healthy (reviews the nature of teachers' health disorders) is followed by the personal health practices of teachers (the diet section being prepared by Mary S. Rose and Clara M. Taylor). The mental health and the spiritual health of teachers, and the school environment are presented. Factors outside the school, and community responsibility in the promotion of teacher health are discussed. Considerable importance is attached to health promotion by teachers' professional organizations, and in the pre-service training of teachers. Good health as a prerequisite for certification, and as a factor in employing teachers, is emphasized.

The questionnaires, duplicated in the appendix, might well be used in further local studies, and as checklists for administrators and individual teachers. Civic and health workers concerned with the health of teachers and health teaching by teachers cannot afford to overlook this volume.

EVART G. ROUTZAHN

Let's Grow and Let's Stay Well—*By Mary L. Hahn and Charles-Edward Amory Winslow, Dr.P.H., New York:*

Merrill, 1938. 186 and 184 pp. Price, \$.72 each.

Let's Grow and *Let's Stay Well* are the Third and Fourth grade books, respectively, of the New Healthy Living Series by these authors. They are designed to meet the major objectives of health instruction in these two grades. The type used is easy on the eyes. The chapters average 8 pages each. The material used aims at maintaining real child interest in the true-to-life experiences of the children in the books. The health program presented is definite and complete. Emphasis is placed upon good health rather than upon sickness.

W. W. PETER

Health—*By C. E. Turner, Dr.P.H., Sc.D., and Georgie B. Collins. Boston: Heath, 1937.* 231 pp. Price, \$.72.

Cleanliness and Health—*By C. E. Turner, Dr.P.H., Sc.D., and Georgie B. Collins. Boston: Heath, 1937.* 236 pp. Price, \$.80.

According to the publisher's blurb there are "one hundred forty-six health habits, fundamental to physical and mental health"—a number sufficient to stimulate many authors to writing text or guide books for teachers who otherwise might omit stressing some or get all confused.

Both of these books are revisions. *Health* for grade V and *Cleanliness and Health* for grade VI. The method followed by the authors is quite in contrast to *Let's Grow* and *Let's Stay Well* by Hahn and Winslow. The former books might be edited stenographic records of interesting health talks; the latter employ dialogue chiefly.

W. W. PETER

Intensive Rural Hygiene Work in Netherlands India—*Public Health Service of Netherlands India, Batavia, Java, 1937.* 170 pp., 144 ill.

This book is much more than a de-

lightful report of outstanding public health work; it is a philosophy of public health expressed in terms of successful experience. From a recent visit to Java, the reviewer can certify that the accomplishment and philosophy expressed are fully borne out in the splendid work being carried forward by the Dutch Colonial Service.

The intensive rural hygiene work described is essentially a program of sound, practical, constructive health education applied to rural sanitation, and especially to hookworm control. It is succeeding much better than did sanitary ordinances or curative medicine. The philosophy, or point of view, upon which it is based may best be expressed by a few selected sentences from the book itself:

An attempt to carry out hygienic measures by beginning with the use of force gives rise to active and passive resistance . . . Medical care can be carried out by a central government organization, a local government organization, a society et cetera, but it should not be included in the program of a public health service . . . The teaching of hygiene cannot be based efficiently upon medical care, but should be based upon educational measures . . . Medical care and hygiene work concern such different fields of activity that for efficient work there should be a different subordinate personnel for each field wherever this is possible . . . Those who have once worked with activities that concern medical care will not willingly give up this attractive care of the sick which is satisfying to them to carry on hygiene work which is much more difficult and the results of which cannot be seen immediately, but will be secured much later. For this reason pure hygiene work is nearly always postponed. Medical care is much easier than hygiene work, it is more attractive, the results are immediately seen, the patients come to the doctor, and everything runs more smoothly than with hygiene work . . . The people must seek their health not in clinics or hospitals, but must try to find it in hygienic habits and hygienic surroundings.

Detailed descriptions of the health education procedures are presented and the plentiful illustrations charmingly depict the health education methods and

also the habits, problems, living conditions, and accomplishments of the Javanese villagers.

The delegates from Indo-China at the recent Rural Hygiene Conference in Bandoeng were so impressed with this work that the book is now being translated into French.

Every health educator and every health officer would be challenged and stimulated by this book. Inquiry has revealed that there are a few hundred copies of this report still available to professional workers who are really interested in the problem. Requests should be sent to the Director of the Public Health Service of Netherlands India, (Dienst der Volksgezondheid) Parapattan 10, Batavia-Centrum, Java, N. I.

C. E. TURNER

Tuberculosis Among Children and Young Adults—By J. Arthur Myers, Ph.D., M.D. (2nd ed.) Springfield, Ill.: Thomas, 1938. 401 pp., 71 ill. Price, \$4.50.

The first edition of this book appeared in 1930 and now, 8 years later, the author has drawn on his added, rich experience and the multitudinous, valuable contributions that have been made to the literature on the subject of tuberculosis among children and young adults to bring together into one compact volume the latest information on the diagnosis, treatment, and prevention of the reinfection type of pulmonary tuberculosis.

Beginning with an account of the results of recent research in the field of tuberculosis control, including Purified Protein Derivatives, X-ray, Sedimentation Rate, Animal Experimentation, Epidemiology, Sociological considerations, sanatorium treatment, etc., the author then devotes a chapter to sensitization and immunity, discussing the effects of sensitization, the detection of sensitiveness, the dangers of a high degree of sensitization and the

significance of the negative tuberculin reaction in persons who have been exposed to an open case of tuberculosis for a comparatively long period of time.

Concerning immunity to tuberculosis Dr. Myers summarizes the 6 pages of discussion as follows:

Attempts to produce immunity in various animal species have brought about a wide range of results. Therefore, it does not appear safe to draw conclusions concerning the immunizing effect of tuberculous infection in man from the results obtained in any one animal species. The incidence of disease in the various races is not an index to immunity. The best test of the immunizing effect of the first infection type of tuberculosis is made by observing what actually happens among groups of children who have developed this type of disease. Wherever such observations have been made over a sufficiently long period of time, the results are very discouraging to those who would like to depend upon immunity for protection against clinical tuberculosis.

Tuberculosis in Infancy, Tuberculosis in Childhood, and Tuberculosis Among Young Adults, are the principal subdivisions of the book. The chapters have been prepared carefully and with an eye to an orderly presentation of the facts. Contributing authors have written the chapters on Tuberculous Meningitis, Tuberculous Disease of the Bones and Joints, and Chronic Non-tuberculous Basal Pulmonary Diseases in Childhood.

Especially valuable are the summary and bibliography at the end of each chapter. No effort has been spared in presenting as exhaustive a compilation of modern references as possible, and this feature should make the volume an important addition to the technical libraries of all persons interested in tuberculosis in children and youth. The index is unusually complete.

BERNARD S. COLEMAN

Pulmonary Tuberculosis in Practice—By R. C. Wingfield, B.A., M.C., B.Ch., F.R.C.P. Baltimore: Wood, 1937. 122 pp. Price, \$2.50.

This book, as we are told in its preface, is intended

... to bridge the gap between the practitioner and the specialist. An attempt to show the senior student and the young practitioner that if he will approach tuberculosis from a new and simpler angle he can study the disease in his practice and that with only a broad knowledge of those parts of the diagnosis, assessment and treatment, that must of necessity call for the specialist's skill, he can really take a hand in the treatment of his cases and need no longer drop them like hot coals as soon as they are diagnosed.

The author has undoubtedly had broad experience in the management of tuberculosis and the present volume is a direct result of his intimate acquaintance with actual needs of practitioners with whom he has had contact. The text is most interestingly presented; the arrangement of the material follows closely and in careful detail the train of events along their various courses from the primary tubercle to complete healing or to massive cavitation. The chief diagnostic aid is the roentgenogram. The method of classifying lesions is the author's own; in America we cannot feel this to be superior to the classification of the American Association. His idea that allergy is not a manifestation of immunity will probably be changed as he studies this part of the problem more closely. We cannot agree that an ischio-rectal abscess should ever be poulticed and think the book would have made more friends if this section had been omitted.

These comments are trivial compared with the wealth of information this volume contains. Anyone concerned with the clinical management of pulmonary tuberculosis will find it profitable and interesting reading. It is profusely illustrated with cuts made from roentgen ray pictures and especially by a large chart showing graphically the important stages in the development of tuberculous lesions of the lung.

Supplementary chapters discuss: "The Mantoux Reaction" (apparently the author does not know about P.P.D.), "Haemoptysis," "Pleural Effusion," "Ischio-Rectal Abscess," "Spontaneous Pneumothorax" and "Tuberculous Laryngitis."

A. P. HITCHENS

Fifty Years a Country Doctor—
By William N. Macartney. New York: Dutton, 1938. 584 pp. Price, \$3.50.

Only the other day I was reading an article of the kind now all too common, dwelling on specialism in medicine as well as in doctors, and claiming that the family doctor had passed from the picture, leaving would-be patients confused and unhappy.

The first page of this excellent book combats the idea that the general practitioner is passing or has passed and that the day of the specialist has arrived. It claims that two-thirds to three-fourths of the population are still treated by their family physicians and says, "The species is a long way from extinction; they are a hardy breed and will survive." There is no doubt that many people will be glad to know this. Certainly we owe more to the country doctor than we can ever repay. It is well to remember that Marion Sims, McDowell, Drake, and a host of others who have added much to our medical history were country doctors.

The book before us is extremely interesting, a good story of a useful life, well written by the best type of country doctor. Autobiographies are always interesting when they are sincere. The story of Dr. Macartney is not only sincere but is filled with a kindly philosophy tempered by a shrewdness evidently due to the Scotch-Irish descent which he claims. Further than this, it gives us a picture of a number of the great men whose names are household words in American medicine, such as Loomis, Draper, Witthaus, Gaillard

Thomas, Austin Flint, Sr., Phelps—and perhaps of greatest interest to the readers of this *Journal*—Stephen Smith, the founder of our Association.

Almost every page gives some amusing incident, many of which are credited to certain characters who are perhaps more or less composite but who the author assures us actually were friends of his. We are quite prepared to see some of these—Uncle Eph, Si Perkins as well as Si Perkins's wife, and Dr. Jenkins—become well known characters.

We commend this book heartily from every standpoint, and hope for a long survival of the type of country doctor illustrated in the life of the author.

MAZÏCK P. RAVENEL

Personnel Policies in Public Health Nursing—*By Marian G. Randall. New York: Macmillan, 1937. 170 pp. Price, \$2.00.*

This book should be in the hands of every public health administrator, director of nursing bureau, and director of a public health nursing agency. The material discussed is based on a study made of personnel practices in 59 official agencies. Every chapter is full of meat for those interesting in improving personnel and the conditions which make for their well-being.

The author throws out a challenge in the introduction by stating: "At present the need for *qualified personnel* is still the *major administrative problem* of public health." Later she says "standards are maintained and improved by the efforts *from within the profession* or group." This follows the recommendation that a nursing advisory committee be appointed in each community to assist the Civil Service Commission in setting up standards, etc.

The most encouraging item in the book is the comparison of the preparation of public health nurses in official agencies today with that of those in-

cluded in the study made by the National Organization for Public Health Nursing 6 years ago. In addition to the tables giving this comparison, the author points out that approximately two-thirds of all directors and one-third of all supervisors have college degrees; nearly three-fourths of the directors and over three-fourths of the supervisors have public health nursing certificates, and the percentage of field staff having certificates has more than doubled in 6 years.

What is not generally understood by many boards and some officials is the fact that staff nurses working without supervision need more academic and professional experience—not less—than those with supervision. This study indicates for the total group that the higher salaries paid to public health nurses are in direct relation to higher education, both professional and academic. Several health officers and nursing directors said they would like to have salaries based on efficiency but had not devised a practical method of putting this into effect because of rating difficulties. It is encouraging that there is a trend toward increasing the probationary period used in many agencies from 3 months to 6 months, and the recommendation is made that where possible, a year be considered.

An important point brought out in connection with dismissal policies is that careful records of work and reports of agencies should be made out periodically for every nurse on the staff. These reports should also show that the records have been discussed with the nurse. In connection with the promotion policies, although length of service is the usual basis upon which promotions are made, it is generally agreed that an objective rating of services and promotion based on efficiency are more satisfactory to both the organization and the worker.

Excellent data have been made available

in regard to health examinations, citizenship, age, personality, hours of work, vacations, leaves of absence, retirement, pensions, and insurance. In fact, this book based upon a field study of personnel practices in various parts of the country is full of valuable information for the administrator in public health nursing, and its recommendations, presented in the fore part of the book, are a challenge to us all.

MARGUERITE WALES

Methods of Analysis for the Butter Industry—*Edited by J. C. Fridenberg. Chicago: American Butter Institute, 1937. 48 pp. Price, \$1.00.*

A laboratory manual is of value only in so far as its procedures are accurate, reasonably simple, and relatively inexpensive to conduct. This loose-leaf booklet adequately satisfies these conditions not only for the butter industry but also for food and dairy inspectors, laboratory workers, and even consumers.

The book is divided into 10 sections, each devoted to a phase of analysis. In addition to notes on sampling and methods for the determination of quality and composition of butter, the manual contains fat, sediment, and acidity tests for milk, skim milk, and cream. One section is devoted to the determination of diacetyl and acetylmethylcarbinol (the flavor factors) in butter and butter starters. A practical method for determining the keeping quality of butter is also presented. The last section of the book outlines methods for checking those acidity and salt test solutions which are subject to variation. An ever useful temperature conversion table is also included.

The methods outlined in this manual are those which are used by the American Butter Institute's Laboratory and may well be considered sufficiently accurate and simple for most routine semi-official butter tests.

C. R. FELLEYS

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Measles Statistics—Current measles incidence is the highest on record, but it is declining. Highest incidences were reported in the east, north central, and east south central regions, where the disease was more than 4 times the seasonal expectancy. Useful graphs.

AXON. *Prevalence of Communicable Diseases in the United States*. Pub. Health Rep. 53, 19:747 (May 13), 1938.

For Hot Weather Vaccinations—Research is reported which leads to the recommendation that vaccine virus propagated on chick membrane be dried, ground, and diluted with serum to make it resistant to the heat ordinarily encountered in hot weather, which so often inactivates ordinary saline diluted virus.

BIDDINGH, G. J. *The Use of Serum as a Protective Diluent for Vaccinia Virus*. Am. J. Hyg. 27, 3:530 (May), 1938.

The Slaughter of the Tonsils—Among 8,758 white families in 18 states, a surgical operation rate of 65 operations per 1,000 persons per year was reported. Highest rates were found in the 5-9 and 30-34 year age groups, the first for tonsillectomies, the second for female genital and puerperal conditions. Tonsillectomy accounts for a third of all operations, setting fractures stands second, and appendectomy third. Significant sex differences in various operations are recorded.

COLLINS, S. D. *Frequency of Surgical Procedures Among 9,000 Families, Based on Nation-wide Periodic Canvasses, 1928-1931*. Pub. Health Rep. 53, 16:587 (Apr. 22), 1938 (or) Milbank Quart. 16, 2:123 (Apr.), 1938.

Some Meditations on Tuberculosis—In New England female tuberculosis death rates exceeded the male until about the end of the last century: since that time the male rates have been in excess. In the South, mortality has been consistently higher among men. Whatever has affected the rate among young children has affected each sex about equally. The more rapid decline among adult females may be due to the fact that women being largely employed in household duties have responded more quickly to better living conditions than their husbands.

DAUER, C. C. *Sex Differences in Trends of Tuberculosis Mortality*. Am. J. Hyg. 27, 3:538 (May), 1938.

Frequency of Disabilities—Over a 5 year period disabling illnesses and non-industrial accidents of 8 or more days' duration occurring in a large group of white male employees were recorded. The annual rate per 1,000 was 132 (when adjusted for age, 124). In this study you will find some important records of duration of illness, incidence, distribution, etc.

GAFAR, W. M. *Frequency of Sickness and Non-Industrial Accidents Causing Disability Lasting Eight Calendar Days or Longer Among 60,000 White Male Railroad Employees, 1930-1934 Inclusive*. Pub. Health Rep. 53, 15:555 (Apr. 15), 1938.

Disulfide Poisoning—To the list of industrial health hazards must be added carbon disulfide poisoning. Viscose plants manufacturing rayon use the chemical, as do some rubber manufacturers. As a minimal standard of

safety an atmospheric concentration of 10 p.p.m. is suggested.

GORDY, S. T., and TRUMPER, M. Carbon Disulfide Poisoning. J.A.M.A. 110, 19: 1543 (May 7), 1938.

For V. D. Clinicians—British findings that sulfanilamide will clear up chancroid quickly.

HANSCHALL, H. M. Sulfanilamide in the Treatment of Chancroid. Lancet. 1, 16:886 (Apr. 16), 1938.

Brucellosis Incubation Periods—Most observations of the incubation period of undulant fever have indicated 14 days as the usual, with 3 to 20 days as the extreme limits. Experimentally induced infections increased the limits to 28 to 35 days. Study of 17 city cases infected by drinking contaminated milk in the country reveals incubation periods of from 1 week to not less than 4 months.

HARDY, A. V., *et al.* The Incubation Period of Undulant Fever. Pub. Health Rep. 53, 20:796 (May 20), 1938.

Whooping Cough Prophylaxis—One dose of alum-precipitated pertussis vaccine was given to a group of children. A control group and the treated children were watched for a year. Reactions following immunizations were negligible. Fewer cases of whooping cough occurred among the treated than the control children and attacks were milder. The experience indicates that larger doses of the antigen should be tried.

HARRISON, W. T., *et al.* Prophylactic Value of a Single Dose of Precipitated Pertussis Vaccine. Pub. Health Rep. 53, 20:793 (May 20), 1938.

Better Measles Prophylaxis—Globulins recovered from adult serum proved effective in preventing development of measles in exposed children. The prophylactic is urged for further trial, for it produced no reactions, the amount to be injected is small, and the supply unlimited.

KARELITZ, S. Prophylaxis Against Measles With the Globulin Fraction of Immune Human Adult Serum. Am. J. Dis. Child. 55, 4:768 (Apr.), 1938.

Starting from Scratch against Polio—How little we know about the cause, treatment, and prevention of poliomyelitis is told with openmindedness and with complete frankness. Especially in preventive knowledge are we woefully wanting.

LUMSDEN, L. L. Poliomyelitis: Facts and Fallacies. South. M. J. 31, 5:465 (May), 1938.

Decibels and Deafness—Excessive noise impairs the efficiency of workers by affecting hearing, producing fatigue and neuroses, and interfering with sleep. Noise can be measured and rough standards of safety established. Air conditioning tends to reduce outside noises, some inside noises may be eliminated at the source, and there are measures by which the individual may protect himself.

MCCORD, C. P., *et al.* Noise and Its Effect on Human Beings. J.A.M.A. 110, 19:1553 (May 7), 1938.

Fertile Families—In the 1930 census, questions were asked about children under ten years in each home. While the findings do not indicate the birth rate, they do reveal some interesting comparisons: fertility is inversely related to community size; negroes have lower average fertility than whites (though those negro women who have any children have more); in general, fertility and economic status are inversely related, with the exception of the highest value-of-home groups.

NOTESTLIN, F. W. Differential Fertility in the East North Central States. Milbank Quart. 16, 2:173 (Apr.), 1938.

All That Can Be Told About Colds—Excellent summarizing the best available present-day information about colds, the author begins with the

warning that in the pamphlet will be found nothing new or startling, and no revolutionary ideas about the cause, prevention, or treatment.

OLESEN, R. Common Colds. *Pub. Health Rep. Supplement No. 135* (May), 1938.

Three Generations of Rheumatism

—Studies of the history of rheumatic infection among relatives of children with rheumatic disease and relatives of a control group of children revealed a high frequency among the relatives of the infected children and a low frequency among the others. These findings, indicative of a familial tendency to the disease, suggest a constitutional susceptibility, but cannot eliminate exposure as the important factor. More study is suggested.

READ, F. E. M., *et al.* The Frequency of Rheumatic Manifestations Among the Siblings, Parents, Uncles, Aunts, and Grandparents of Rheumatic and Control Patients. *Am. J. Hyg.* 27, 3:719 (May), 1938.

Baby's Habits—Written for nurses, but there is much here of interest to all health workers. There are recognized behavior patterns of each age level: when they are not reached it is a sign something is wrong. With sufficient outside pressure a degree of conformity to expected behavior patterns may sometimes be obtained, but this may not be desirable. We are learning now that rigid schedules may not be best; how much individual freedom to allow is the problem.

ROBERTS, D. I. Changing Concepts of Child Training. *Pub. Health Nurs.* 30, 5:283 (May), 1938.

Children Lose Immunity—An apparent increase in diphtheria among supposedly immunized children leads these authors to recommend that children treated in infancy be tested and immunized again if necessary when entering school.

SCHWARTZ, A. B., and JANNEY, F. E. The Need of Redetermining Schick Negativeness

in School Children. *J.A.M.A.* 110, 21:1743 (May 21), 1938.

New Public Health Objectives—

Repeat this mouthful to yourself: any disease or condition causing widespread morbidity, about which existing scientific knowledge, if applied, would prevent, cure, or alleviate, but is not applied for some reason, is a public health problem. When that has sunk in, you have a starting point for a profound public health discussion, of which this is an excellent example.

SINAI, N. Health As a National Asset. *Pub. Health Nurs.* 30, 5:287 (May), 1938.

The Grim Reaper's Stealth—

In childhood, healthy growth and the progress of disease are easily distinguished because both show vigorous change; infirmity in childhood is not so easily recognized. In maturity changes due to aging are slow and not easily noticed, and infirmity may be confused with aging, which is a process of adaptation in structure and function. Criteria of healthy aging are not clear-cut; resilience is lessened, speed of reaction is curtailed, staying power is diminished, but portents of disaster are similar throughout life.

TODD, T. W. Aging Versus Infirmity. *Sci. Month.* June, 1938, p. 545.

Some Lives That Should Be Saved

—Excess of deaths among males over females is highest in the "prime of life" and at this age the excess has been mounting steadily. Incidentally, it is higher in the United States than in Canada and other countries, so there must be some other than a biological factor responsible. The excess of male deaths in the 25-44 year group is important because such deaths should be postponable, and they occur at the time of greatest economic usefulness of the men.

WIEHL, D. G. Sex Differences in Mortality in the United States. *Milbank Quart.* 16, 2:145 (Apr.), 1938.

"Bachelor Scurvy" and Other Disorders—Three useful lectures on nutritional deficiencies and deficiency diseases beginning with a thought provoking quotation to the effect that the best fed people nowadays, though get-

ting twice as much vitamin B as those on low incomes, consume less vitamin B than the parish poor in the early 19th century.

UNGLEY, C. C. Some Deficiencies of Nutrition. *Lancet*. 1, 16:875 (Apr. 16), 1938.

ASSOCIATION NEWS

THE HEALTH CONSERVATION CONTESTS

THE Health Conservation Contests for cities and rural areas, conducted jointly by the United States Chamber of Commerce and the American Public Health Association, have completed another year. Elsewhere* announcement has been made of the winners for 1937, during which year the City Contest completed its ninth year and the Rural Contest its fourth. The Rural Contest is supported financially by the W. K. Kellogg Foundation, and the City Contest by several insurance companies.

Among the outstanding features of the 1937 Contests were: the participation by the Canadian provinces in the Rural Contest, the two new special Contests for excellence in tuberculosis and syphilis control, and the general expansion of both the Rural and City Contests in the United States. The Canadian Contest, new in 1937, was sponsored jointly by the Canadian Public Health Association and the American Public Health Association.

Both the City and Rural Contests showed substantial growth in the number of areas participating. Of the urban population in the United States, more than 3 million additional persons were included in participating cities in 1937 than in 1936, while in the Rural Contests in the United States there was an increase of almost 17 per cent in the number of rural units submitting schedules.

The Canadian rural units set a remarkable all-time record by enrolling

almost 100 per cent of their units, and of these units more than 90 per cent submitted schedules. To Quebec Province goes the international record of enrolling 35 units and having 32 submit completed schedules. All together, 37 states, 4 Canadian provinces and Hawaii were included in the areas competing for awards.

It was apparent to the Grading Committee at its April meeting that the interest in the Health Conservation Contests is increasing and not waning; for example, in 1937, 263 cities participated and of these, 26 were new cities, while 241 rural units enrolled, of which 34 were new. Most encouraging in the schedules were the many improvements in basic public health which were reported. In no previous year have so many additions to personnel been made, in no other year have we seen so much improvement in the office equipment of health departments and in no previous year has it been possible to cite so many activities or such intensification of existing activities in the local programs.

There has been a significant shift between the City and Rural Contests because of the fact that, with the growth of organized rural full-time health service, many smaller cities are now corporate parts of rural units. There were 15 cities which have been enrolled in the City Contest which in 1937 took their place as a corporate part in the participating rural units. All together, across the years, there are 57 cities formerly participating in the City Contest which are now a part of rural units.

* *A.J.P.H.*, June, 1938, p. 795.

Field service to enrolled cities and counties has been at a high level in 1937. In addition to the 17 rural units representing 23 counties in Canada which were given field service, there were 120 individual county rural units and 19 districts embracing 64 counties which were visited in the United States. One hundred fifty-six rural visits were made to 207 rural counties. Funds have been available only to a limited extent for field service to cities but 55 visits have been paid to cities and, as a result, certain important areas are now included for the first time in the Contest. This field service, in addition to the visits to state health departments, made personal contacts with local

health departments in 28 states, 2 provinces, and the District of Columbia. Since the establishment of the Rural Contest in 1934, 343 different rural units representing 387 counties in the United States have been visited, in addition to the 23 Canadian counties, or a total of 410 counties in the two countries.

While emphasizing the important part which the local business man plays in the Health Conservation Contests, a well informed physician recently stated, "If there has been a recession in business, there has been no recession by business men in their interest and effort to make their communities safe for the democracy of public health."

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Harry S. Allen, M.D., 322 N. 6 St., Ironton, O., Health Commissioner
 Will H. Aufranc, M.D., Health Office, Kennett, Mo., District State Health Officer
 Seth S. Barnes, M.D., 222 Independence St., Cape Girardeau, Mo., District State Health Officer
 Edgar E. Berg, M.D., Flavel House, Astoria, Ore., Clatsop County Health Officer
 Arthur D. Blackburn, M.D., Court House, Circleville, O., Pickaway County Health Commissioner
 Howard E. M. Boocks, M.D., East Main St., Logan, Ohio, City Health Commissioner
 Walter J. Broad, M.D., Geneva, Ala., Geneva County Health Officer
 Enoch M. Bryan, M.D., Fredericktown, Mo., District State Health Officer
 Andrew Carney, 121 Prospect St., Westfield, N. J., Executive Officer, Board of Health
 Warren D. Carter, M.D., C.P.H., Box 625, Morganton, N. C., Burke-Caldwell District Health Officer
 Dr. Gonzalez Corbalan Trumbull, Casilla 518, Santiago de Chile, S. A., Jefe del Departamento de Sanidad Internacional del Servicio de Salubridad Publica de Chile
 Charles L. Coyle, M.D., Court House, Coquille, Ore., Coos County Health Officer
 John D. Fuller, M.D., Santa Cruz County

Hospital, Santa Cruz, Calif., County Health Officer
 G. G. A. Herzog, M.D., Highway 66, Cuba, Mo., County Health Officer
 Shelton E. Johnson, M.D., 5810 Cowen Place, Seattle, Wash., Specialist Physician, U. S. Dept. of the Interior
 Alfred H. MacLaren, M.D., City Hall, Pendleton, Ore., Director, Umatilla County Health Unit
 Charles W. Meinershagen, M.D., Salem, Mo., District State Health Officer
 Joseph R. Morrell, M.D., 2535 Eccles Ave., Ogden, Utah, President, State Board of Health
 William J. Sullivan, M.D., Kirksville, Mo., District State Health Officer
 Dan P. Trullinger, M.D., Rm. 304, Court House, Oregon City, Ore., Acting County Health Officer, Clackamas County Health Unit
 Luther P. Walter, Jr., M.D., City County Health Unit, El Paso, Tex., Assistant Director

Laboratory Section

David M. Baldwin, 1118 Washington Ave., Philadelphia, Pa., Bacteriologist, John Wyeth & Bro., Inc.
 Georgene W. Blauer, Rt. 4, Box 288, San Jose, Calif., Student

Evalyn J. Cowan, 901-6th Ave., Seattle, Wash., Assistant Bacteriologist, State Dept. of Health

Felix E. Fernandez Garcia, M.D., Luis Estevez 461, Vibora, Habana, Cuba, Chief, Bacteriological Dept., National Laboratory

Maude W. Fos, 1960-9W., Seattle, Wash., Bacteriologist, State Dept. of Health

John T. Glenn, Jr., Glenolden, Pa., Bacteriologist, Mulford Biological Laboratories, Sharp & Dohme

Maud Gober, State Board of Health, Jackson, Miss., Bacteriologist

Josie Haried, State Dept. of Health, Lansing, Mich., Senior Chemist

J. V. Irons, Sc.D., 705 E. 17th, Austin, Tex., Assistant Director of Laboratories, State Dept. of Health

Paul W. Kabler, M.D., Ph.D., State Dept. of Health, University Campus, Minneapolis, Minn., Assistant Chief of Laboratories, Division of Preventable Diseases

E. Lynn Kisner, 12 Municipal Courts, St. Louis, Mo., Supervisor of Chemistry, Health Division

William V. Knoll, M.D., 1200 N. State, Los Angeles, Calif., Clinical Laboratory Worker, Los Angeles General Hospital

Alice McElroy, 1225 Walnut St., Alameda, Calif., Student

Carrie A. Moorman, 1417 Smith Tower, Seattle, Wash., Bacteriologist, State Dept. of Health Laboratories

Questa G. Mountain, 1417 Smith Tower, Seattle, Wash., Laboratory Technician, State Dept. of Health

Charles R. Nicewonger, 159 Tamalpais Rd., Berkeley, Calif., Student

Bernice M. Pedersen, 1417 Smith Tower, Seattle, Wash., Laboratory Technician, State Dept. of Health

Norman B. Powell, 212 E. Parkway Drive, Columbia, Mo.

Frederick P. Sparks, M.D., Kootenay Lake General Hospital, Nelson, B. C., Canada, Medical Health Officer and Director of City Laboratory

Alexander I. Teplow, 426 N. Virgil Ave., Los Angeles, Calif., Technician, Los Angeles County General Hospital

Ernesto Trelles y Duelo, Edificio Govea 13 y 18 Vedado, Havana, Cuba, Chief Chemist and Bacteriologist, Havana Water Works

Vital Statistics Section

Margaret O. Swenson, State Office Bldg., St. Paul, Minn., Statistician, Division of Vital Statistics, State Dept. of Health

George K. Traver, 396 Union Ave., West Haven, Conn., Registrar of Vital Statistics

Public Health Engineering Section

Robert R. Balmer, Jr., 17 Eden St., Salem, Mass., Junior Sanitary Engineer, State Dept. of Public Health

A. R. Baron, Fredericktown, Mo., District State Public Health Engineer

Theodore J. Bommer, 327 E. Stoddard, Dexter, Mo., Public Health Engineer, State Board of Health

John M. Borden, 605 Jackson St., Oregon City, Ore., Clackamas County Sanitarian

James B. Carey, 2352 Winchester Ave., Ashland, Ky., Eastern District State Sanitary Engineer

Carl V. Erickson, Urbana and Champaign Sanitary District, Urbana, Ill., Manager

Wallace G. Grange, 316 N. 2nd E., Price, Utah, City Sanitarian

Richard S. Green, 101 Willow Ave., Somerville, Mass., Senior Sanitary Engineering Aid, Division of Sanitary Engineering, State Dept. of Public Health

William A. Hasfurther, 7723 S. Ada St., Chicago, Ill., Sanitary Engineer, State Dept. of Health

Edward O. Madison, 2411 N. Charles, Baltimore, Md., Assistant State Director, Community Sanitation Program, U. S. Public Health Service

Harold F. Rock, 46 Petrova Ave., Saranac Lake, N. Y., Junior Sanitary Engineer, State Dept. of Health

Claude Strickland, 1703-40 St., S., St. Petersburg, Fla., Supt., Pinellas County Anti-Mosquito District

Carmen A. Sullivan, Box 103, Ontonagon, Mich., Sanitarian, State Dept. of Health & Children's Fund

Food and Nutrition Section

M. Thomas Bartram, Ph.D., Food and Drug Admr., U. S. Dept. of Agr., Washington, D. C., Assistant Bacteriologist

Martha Koehne, Ph.D., 75-18 Ave., Columbus, O., Nutritionist, State Dept. of Health

Ralph L. MacNeil, 3433-90 St., Jackson Heights, L. I., N. Y., Chemist, Bureau of Food and Drugs, Dept. of Health

Esther Pickios, 55-21-138 St., Flushing, L. I., N. Y., Student

William J. Wollesen, Jr., 711-6 Ave., San Francisco, Calif., Trainee, Sanitary Inspector, University of California School of Public Health

Child Hygiene Section

Allen O. Gruebbel, D.D.S., State Board of Health, Jefferson City, Mo., Dental Director, Child Hygiene Division

Marie A. Hagele, M.D., 1819 W. Polk St., Chicago, Ill.
 Frank T. Jones, D.D.S., 306 State Bldg., San Francisco, Calif., Dentist, State Dept. of Public Health
 Arthur W. Stahl, M.D., 238 Republic Bldg., Denver, Colo., Denver Public Schools
 G. D. C. Thompson, M.D., 816 Oregon Bldg., Portland, Ore., Director, Division of Maternal and Child Health, State Board of Health

Industrial Hygiene Section

Arthur M. Master, M.D., 125 E. 72 St., New York, N. Y.

Public Health Education Section

Alice M. Bahrs, Ph.D., 10 & Montgomery Sts., Portland, Ore., Head of Science Dept., St. Helen's Hall Junior College
 Darrell A. Dance, P. O. Box 202, Mays Landing, N. J., Sanitary Inspector, State Dept. of Health
 Alfred Korach, M.D., 1640 Cambridge St., Cambridge, Mass., Visiting Lecturer in Public Health Administration, Massachusetts Institute of Technology
 Elizabeth McGuire, 1017 W. 31st, Austin, Tex., Organizer of County Children's Councils, State Dept. of Health
 Grace C. Nason, Box 303, Moab, Utah, Public Health Nurse, State Board of Health
 Alexander J. B. van Beyer, Dr.P.H., 308-16 S. Craig St., Pittsburgh, Pa., Director, Prevention of Blindness Dept., Pa. Assoc. for the Blind

Public Health Nursing Section

Catherine O. Beagin, R.N., P. O. Box 1854, Miami, Ariz., School Nurse
 Helen P. Bott, Price, Utah, County and School Nurse, State Board of Health
 Lula M. Champion, 105 E. Bexar, Crystal City, Tex., County Public Health Nurse
 Eunice Lamona, R.N., 6028 Harcourt Ave., Los Angeles, Calif., Chief Nurse, Board of Education
 Mabel A. Patton, State Board of Health.

Raleigh, N. C., Consultant in Public Health Nursing, State Board of Health
 Margaret L. Payton, R.N., Court House, Oregon City, Ore., Senior Public Health Nurse, Clackamas County Health Unit
 LaVerna Peterson, 2329 Monroe Ave., Ogden, Utah, Acting Director, Division of Public Health Nursing, State Board of Health
 Lydia Potthoff, R.N., 727 E. Willette, Phoenix, Ariz., Nursing Consultant, State Board of Health
 Helene K. Sabert, R.N., Board of Health, Honolulu, T. H. (Student until August). Nursing Supervisor
 Muriel Schopp, 3085 Andover Drive, St. Louis County, Mo., Public Health Nurse
 Louise Schott, R.N., Benton, Mo., District State Health Nurse
 Marcella A. Schumer, Perryville, Mo., District State Health Nurse
 Laura P. Stead, 35 E. Lakeview Ave., Columbus, O., Field Representative, State Dept. of Health
 Luella M. Stickney, State Board of Health, Helena, Mont., Maternal and Child Health Field Advisory Nurse
 Hedwig B. Trauba, 130 State Capitol Bldg., Salt Lake City, Utah, Assistant Director and Orthopedic Nursing Consultant, State Crippled Children's Service
 Martha J. West, R.N., P. O. Box 769, Price, Utah, Public Health Nursing Supervisor, State Board of Health
 Rosannah Winter, R.N., 3211 S. W. 10 Ave., Portland, Ore., Field Nursing Consultant, State Board of Health
 Miriam V. Wolf, 216 Morrison Drive, Toledo, O., Field Nursing Consultant, State Dept. of Health

Unaffiliated

Alice Marshall, 400 Paxton Bldg., Omaha, Nebr., Executive Secretary, Nebr. Tuberculosis Assoc.
 Charles A. Newhall, 6305-21 Ave. N. E., Seattle, Wash., Chemical Engineer, State Dept. of Health

DECEASED MEMBERS

W. Alfred Buice, M.D., Dr.P.H., Chelsea, Okla., Elected Member 1925, Fellow 1934
 W. F. Elgin, M.D., Glenolden, Pa., Elected Member 1900, Fellow 1922
 W. H. Frost, M.D., Baltimore, Md., Elected Member 1909, Fellow 1923
 Frank L. Watkins, M.D., Great Falls, Mont., Elected Member 1927, Fellow 1931

Robert W. Fowler, M.D., Richmond Hill, L. I., N. Y., Elected Member 1937
 Arthur M. Gibbs, M.D., C.P.H., Hamburg, Ark., Elected Member 1931
 Henry S. Plummer, M.D., Rochester, Minn., Elected Member 1924
 Bertha K. Spector, Ph.D., Chicago, Ill., Elected Member 1916

CLOSING DATE FOR SUBMITTING APPLICATIONS FOR FELLOWSHIP

SEPTEMBER 1 is the latest date the Committee on Eligibility can accept Fellowship applications. This date is set in order that there may be sufficient time to route them through the preliminary steps necessary before they

receive final consideration at the hands of the Governing Council during the Kansas City Annual Meeting. Eligible members who wish to apply for Fellowship are therefore urged to submit their applications in the near future.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Joint Vocational Service, 122 E. 22 Street, New York, N. Y., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS AVAILABLE

Wanted: Deputy Commissioner of Health. Midwestern city of 130,000. Under 45 years of age; particularly to be in charge of health of public schools. Give education, experience, qualifications and references. W376

The Civil Service Commission announces nurse positions in the Indian Field Service (including Alaska), Department of Interior. They are:

Public Health Nurse, \$2,000 a year

Graduate Nurse (General Staff Duty), \$1,800 a year

Nurse Technician (Bacteriology and Roentgenology Combined), \$1,800 a year

Closing date for receipt of applications are as follows:

- (a) July 18, 1938, if received from states other than those named in (b) below.
- (b) July 21, 1938, if received from the following states: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, Wyoming.

Write: U. S. Civil Service Commission, Washington, D. C.

POSITIONS WANTED

HEALTH OFFICERS

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, aged 38, with excellent training in medicine, pediatrics, and epidemiology, is completing work for Dr.P.H., and will consider appointment in administration, preferably in county health work. A366

Physician, M.D.; Class A medical school; M.P.H., Harvard School of Public Health; extensive experience in pediatrics and school medical service; also background of county health administration and teaching in medical school, will consider expanded opportunity in teaching or research. A302

Physician, M.D., St. Louis University: postgraduate in eye, ear, nose, and throat; 10 years' experience in public health administration as director of county health units and epidemiologist with state department; also experience in welfare administra-

POSITIONS WANTED (Cont.)

tion; prefers administrative public health position in central or western state. Excellent references. Available July 1. A373

Physician, experienced in health administration of cities and states, will consider attractive opening in maternal and child health or health education. A343

Physician, M.D., Class A school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer, seeks full-time administrative position in city or county. A367

Physician, M.D., McGill; C.P.H., Johns Hopkins; excellent background of communicable disease control and school health service, seeks position as epidemiologist or public health administrator. A368

CHILD HYGIENE

Experienced physician, M.D. and Ph.D., University of Minnesota; specially qualified in maternal and child hygiene, directing state and local programs; will consider position of better sort. A238

HEALTH EDUCATION

Young woman, M.A. in Health Education, Teachers College, Columbia University; with splendid international experience, seeks position as director of health education, with preference for New York City. H369

Sanitarian and health education activity worker with seven years' experience; Dr.P.H., Michigan; desires position in health education and/or social research work. M375

LABORATORY

Young man, A.B. in Chemistry, Phillips University; M.S. in Public Health Laboratory Work, University of Michigan; desires position in state or city health department laboratory. L304

Young woman, M.S., University of Michigan, experienced in biochemistry, bacteriology, water analysis and blood work, will consider research position. L322

Bacteriologist and pathologist with wide administrative experience; Ph.D., Brown University; will consider leading position in his field. L371

SANITARY ENGINEERING

Sanitary engineer, courses at Rutgers University, with 17 years' experience in design, research and construction of water and sewage plants, as well as aerial pollution surveys, desires position, preferably research. E321

Graduate sanitary engineer with service under U. S. Public Health Service and state departments of health, especially interested in filtration plant design and operation and shellfish sanitation, seeks employment. E356

MISCELLANEOUS

Young man, age 27, S.B., Massachusetts Institute of Technology, 1933; A.M., Boston University, 1935; M.S. in Biochemistry, University of Michigan, 1937; 2 years' graduate work in public health. Experienced in chemical, bacteriological and biochemical research; teaching experience in college hygiene, desires position in a food industry involving research or control. M374

NEWS FROM THE FIELD

NATIONAL HEALTH CONFERENCE

THE National Health Conference, called at the suggestion of President Roosevelt, and under the direction of the President's Interdepartmental Committee to Coördinate Health and Welfare Activities, will be held in Washington July 18-20.

Miss Josephine Roche, former Assistant Secretary of the Treasury, is Chairman of the Interdepartmental Committee, appointed by the President August 15, 1935, and consisting of officials of the Social Security Board and the Treasury, Departments of Agriculture, Interior, and Labor. The committee has been assisted in its preliminary work by the Technical Committee on Medical Care, comprising experts from the U. S. Public Health Service, the Children's Bureau, and the Social Security Board.

NEW JERSEY AND NEW YORK PRE-MARITAL EXAMINATIONS FOR SYPHILIS

EFFECTIVE July 1, 1938, Chapter 126 of the New Jersey Public Laws of 1938 requires that each applicant for a marriage license in New Jersey must present a certificate from a qualified physician stating that the applicant has submitted to a standard laboratory blood test for syphilis and that in the opinion of the physician the person either is not affected with syphilis or is not in a stage of that disease which may become communicable. These certificates for each party to be married are attached to the marriage license and remain with the license until the certificate is filed with the State Bureau of Vital Statistics.

No marriage license will be issued in New York State on and after July 1, 1938, unless both parties submit state-

ments that the applicants have been examined and found to be free from syphilis in a stage which may become communicable, according to rules and regulations for the administration of the new amendments to the Domestic Relations Law. The statement, to be submitted on a form provided, must be signed by a licensed physician together with an official statement from a laboratory approved for that purpose showing that the applicant was given an examination including a standard serological blood test for syphilis.

The date of examination will be interpreted to be the date on which the physician takes the specimen of blood from the applicant and which shall not be more than the 20th day prior to that on which the license is applied for unless such time shall have been extended (limited to 90 days). In forwarding completed marriage records to the State Department of Health by the clerk in each case there shall be attached thereto the court order, physician's and laboratory's statement after notation thereof in the register.

PAN AMERICAN SANITARY CONFERENCE

THE 10th Pan American Sanitary Conference will be held in Bogota, Colombia, September 4-18. Some of the subjects to be discussed are: social security in its medical and public health aspects, a Pan American campaign against venereal disease, control and prevention of yellow fever, recent achievements in the study of leprosy and the campaign against the disease, and the problem of germ and virus carriers in epidemiology.

ALABAMA COUNTIES

DR. J. N. Baker, State Health Officer of Alabama, has announced that there is now a full-time health organization in each of the 67 counties of Alabama.

TRAFFIC SAFETY TRAINING

THE National Institute for Traffic Safety Training will be held at the University of Michigan, Ann Arbor, Mich., August 8-20.

Technical courses will be given as follows:

- Traffic Accident Reports and Records—1st week only
- Traffic Safety Education in Schools—2 one week courses
- Examining Drivers' License Applicants—1st week only
- Handling Drivers With Bad Records—2nd week only
- Traffic Engineering
- Training Investigators in Accident Prevention Bureaus
- Safety Organization and Public Education—2nd week only

Some of the topics of general meetings will be:

What Is Safety? The New War on Traffic Accidents. What We Know About Accidents and How We Know It. The Road. The Car. The Driver. The Pedestrian. Speed. Engineering. Enforcement. Mock Intoxication Trial. School and Child Safety. Public Education and Organization.

For information, write: Sidney J. Williams, 20 North Wacker Drive, Chicago, Ill.

SAFETY EDUCATION

NEW York University announces a plan to establish a national center for safety education and accident control, planned primarily for the instruction of teachers, in the University's Division of General Education, July 1. The project will be set up under a special grant of funds from the National Conservation Bureau.

As part of the program, a maximum of 18 research fellowships in safety education, with stipends ranging from \$400 to \$1,200, will be offered for graduate students enrolled in the University's School of Education during 1938-1939 academic year. Applica-

tions for fellowships can be secured from the Fellowship Committee on Safety Education, Division of General Education, New York University, New York, N. Y. They must be filed by July 25, 1938.

COLORADO PUBLIC HEALTH ASSOCIATION

THE Colorado Public Health Association has been organized with A. L. Beaghler, M.D., President; Roy L. Clear, M.D., Vice-President; Omer R. Gillett, M.D., Treasurer; and Lucile O'Reilly, Secretary.

An application has been received for affiliation with the American Public Health Association. The association represents a consolidation of what formerly was The Colorado Council of State-wide Health Agencies and aims to include all the professional public health workers in Colorado.

ALABAMA HEALTH DISTRICT

THE East Alabama Health District, comprising the Counties of Bullock, Chambers, Lee, Macon, Randolph, Russell, and Tallapoosa, has recently been organized with headquarters at Opelika. The new unit is the outgrowth of a field training base at Opelika, which has been conducted by the Alabama State Department of Health.

In connection with the unit, the Rockefeller Foundation has for several years sponsored a clinical research study in tuberculosis.

Arthur H. Graham, D.P.H., M.D., of Opelika, has been named Medical Director of the new health district.

CONSUMERS ORDER USE OF SANITARY UTENSILS

GREENBELT, Md., has the first Coöperative drugstore in the United States.

When it opened April 21, a committee of consumers had ordered that only paper cups be used at the soda fountain.

SOUTH CAROLINA PUBLIC HEALTH ASSOCIATION

THE South Carolina Public Health Association held its annual meeting at Myrtle Beach, S. C., May 23 to 25. The program of several sessions included such subjects as syphilis control, maternity care, general practice and its relation to public health, orthopedic problems, today's trend in public health, malaria control, public health dentistry, the county vital statistics program, public health nursing in crippled children's program, interpretation of laboratory findings, the trend of public health activities in pediatric practice, the sanitation problem created by the touring public, the prevention of blindness, etc.

The following officers were elected:

President, W. B. Furman, M.D., Pickens
President-Elect, G. E. McDaniel, M.D., Columbia
Vice-President, J. R. Wise, Newberry
Secretary-Treasurer, Mrs. Frank George, R.N., Columbia

PUBLIC HEALTH ASSOCIATION OF NEW YORK CITY

THE Public Health Association of New York City held its annual meeting in New York May 18.

New officers elected to serve until the next annual meeting are:

President, Hazel Corbin
First Vice-President, Arthur I. Blau, M.D.
Second Vice-President, George T. Palmer, Dr.P.H.
Secretary-Treasurer, Frank Kiernan

The Executive Board is composed of 12 persons, 6 of whom are elected at each annual meeting. The Directors elected at the May 18 meeting, to serve until 1940, are:

Arthur P. Miller, C.E.
 John Oppie McCall, D.D.S.
 Ralph S. Muckenfuss, M.D.
 John L. Rice, M.D.
 Leopold M. Rohr, M.D.
 Alfred E. Shipley, M.D., Dr.P.H.

The Directors who were elected at the annual meeting in 1937, to serve until the annual meeting in 1939, are:

Donald B. Armstrong, M.D.
 Thomas J. Duffield
 Leonard Greenburg, M.D.
 Helen Manzer, Ph.D.
 Josephine B. Neal, M.D.
 Clarence L. Scamman, M.D.

ILLINOIS HEALTH OFFICERS

THE Illinois State Department of Health announces that the following physicians have been placed in charge of recently established full-time health districts:

James A. Poling, M.D., Freeport—District 4, Lee and Ogle Counties
 Carl A. Peterson, M.D., Moline—District 5a, Henry and Mercer Counties
 Sandor Horwitz, M.D., Peoria—District 6, Marshall, Peoria and Putnam Counties
 John P. Walsh, M.D., Greenview—District 11, Case, Logan and Mason Counties
 Robert H. Bell, M.D., Carlinville—District 12, Calhoun, Greene, Jersey, Macoupin, Morgan, Scott, and (emergency) Bond, Madison, and Montgomery Counties
 Nettie A. M. Dorris, M.D., Paris—District 13, Champaign, Coles, Douglas, Edgar and Vermilion Counties
 Joseph L. Bryan, M.D., Xenia—District 14, Clay, Clinton, Effingham, Jasper, Marion, and (emergency) Fayette Counties.
 Roy W. Harrell, M.D., Carbonvale—District 16a, Jackson, Monroe, Perry, Randolph, Washington, and (emergency) St. Clair Counties.
 Roland R. Cross, M.D., Dahlgren—District 18, Franklin, Hamilton, Jefferson, Wayne and White Counties.
 Lewis S. Barger, M.D., Golconda—District 20, Gallatin, Hardin, Johnson, Massac, Saline, Pope and Williamson Counties.

It is planned to have 20 health districts in Illinois on a full-time basis.

CONNECTICUT PUBLIC HEALTH ASSOCIATION

THE 23rd annual meeting of the Connecticut Public Health Association was held at the Stratfield Hotel in Bridgeport, on May 25.

Approximately 200 persons attended

the several sessions which covered a variety of public health problems. In addition to leading health workers in Connecticut who participated in the program, contributions were also made by Earle G. Brown, M.D., Nassau County Health Commissioner, Mineola, N. Y., James L. Barron, C.E., Director, Division of Sanitation, Westchester County Department of Health, White Plains, N. Y., John A. Ferrell, M.D., Dr.P.H., Associate Director, International Health Division, Rockefeller Foundation, New York, N. Y., and Mary McManus, R.N., Superintendent, Tuberculosis Nursing Service, New York City Department of Health.

Officers for the ensuing year were elected as follows:

President, Professor Ira V. Hiscock, New Haven

President-Elect, Warren J. Scott, S.B., Hartford

Vice-President, Richard O'B. Shea, M.D., Bridgeport

Secretary-Treasurer, Benjamin G. Horning, M.D., Hartford

Representative on Governing Council of the American Public Health Association, Louis J. Dumont, M.D., New Britain

PERSONALS

Central States

CORNELIUS A. HARPER, M.D.,* of Madison, Wis., having completed 34 years as state health officer, is now the senior public health official in the United States from the point of unbroken service. He was appointed to the State Board of Health in 1902 and became the executive in 1904.

JOHN A. MURPHY, M.D., has been appointed Health Commissioner of East Liverpool, Ohio, to succeed Roy C. COSTELLO, M.D.†

DR. BROCKWAY D. ROBERTS, of Wayland, Ia., has been appointed Professor of Hygiene and Director of Student Health at Knox College, Galesburg, Ill.

DR. LOUIS W. SPOLYAR, of Indianapolis, Ind., will be in charge of the new Department of Industrial Hygiene created by the Indiana State Department of Public Health.

Eastern States

S. S. GOLDWATER, M.D.,* since 1934 Commissioner of the Department of Hospitals of New York, N. Y., has announced his retirement, but will continue in office until the appointment of his successor.

GEORGE LAMBERT, M.D., who has been Acting Health Officer, has been appointed Health Officer of Killingly, Conn.

ARTHUR D. MARSH, M.D., has been pointed Health Officer of Scotland, Conn.

J. H. McLAUGHLIN, M.D., succeeds EMILY B. CHATFIELD, M.D.,† as Health Officer of Voluntown, Conn.

THOMAS PARRAN, M.D.,* Surgeon General of the U. S. Public Health Service, was the recipient on June 1 of the degree of Doctor of Science, conferred by Columbia University, New York, N. Y. On June 8, at the 106th commencement of New York University, he received the degree of Doctor of Public Health.

WILFRED J. ROBINSON, M.D., has been appointed Health Officer of East Windsor, Conn., succeeding DR. GEORGE E. PORTER, deceased.

JAMES A. TOBEY, DR.P.H.,* of New York, N. Y., Director of Nutrition of the American Institute of Baking, was awarded the honorary degree of Doctor of Laws at the commencement exercises of Southeastern University in Washington, D. C., on June 7.

ABRAHAM WHITE, PH.D., Assistant Professor of Physiologic Chemistry,

* FELLOW A.P.H.A.
* MEMBER A.P.H.A.

Yale University, New Haven, Conn., received the \$1,000 prize and bronze medal of Eli Lilly and Company, Indianapolis, Ind., at the American Chemical Society meeting in Dallas, Tex., April 18, for his work on sulfur metabolism and protein hormones.

Southern States

DR. FRANCIS J. CLEMENTS, formerly of Palmyra, has been appointed Health Officer of Sussex County, Va., succeeding Dr. JOHN B. H. BONNER.†

DR. ABRAM J. DAVIS, Director of Health of Burke County, Ga., was elected President of the Southeast Georgia Public Health Association at its meeting April 9, in Waynesboro.

SAMUEL R. DAMON, PH.D.,† of Montgomery, Ala., formerly with Johns Hopkins University School of Medicine, Baltimore, Md., has been placed in charge of the laboratories of the Alabama State Department of Health, succeeding JAMES G. McALPINE, PH.D.,† resigned.

DR. JULIUS E. DUNN, formerly Health Officer of DeKalb County, has been appointed Health Officer of Lauderdale County, with headquarters in Florence, Ala.

DR. WILLIAM L. GILBERT, of Atlanta, Ga., Health Officer of Fulton County, has resigned on account of ill health, but will continue in the position until his successor has been named.

DR. GEORGE M. HARMS, of Chatom, Ala., has been appointed Health Officer of Washington County, succeeding Dr. CHARLES M. COLE, resigned.

JOSEPH A. MORRIS, M.D.,† of Oxford, N. C., has been named President of the North Carolina Public Health Association.

DR. GEORGE E. NEWTON was recently named Health Officer of Autauga

County, with headquarters in Prattville, Ala. He held a similar position in Lauderdale County.

DR. FRANCIS W. UPSHUR, of Richmond, Va., has been appointed to direct a program for the control of venereal disease in that city.

Western States

DR. CHARLES A. DAVLIN, of Alamosa, has been elected President of the Denver, Colorado, State Board of Health, succeeding Dr. PAUL J. CONNOR, of Denver.

J. C. GEIGER, M.D.,* Director of Public Health of the City and County of San Francisco, Calif., has had conferred upon him the honorary degree of Doctor of Laws by the University of Santa Clara, at its commencement June 4, on the Campus, Santa Clara, Calif., for his humanitarian activities in the public service.

DR. JULIO R. SOLTERO, of Lewistown, Mont., has been reappointed Health Officer of Fergus County.

DR. WENDELL NOALL has been appointed Health Officer of Ogden, Utah, succeeding Dr. WILBURN J. WILSON.

DEATHS

MAURICE CROWTHER HALL, PH.D., SC.D., D.V.M.,† Chief of the Division of Zoölogy of the National Institute of Health, U. S. Public Health Service, Washington, D. C., died May 1, after a long illness. Though well known for many studies in the field of parasitology, with special reference to the helminths, Dr. Hall was perhaps best known for his discovery in 1921 that carbon tetrachloride is an effective vermifuge for men and animals. In 1925 he announced that tetrachlorethylene is as effective as carbon tetrachloride and apparently much safer.

* Fellow A.P.H.A.

† Member A.P.H.A.

ROYAL S. COPELAND, M.D., Life Member A.P.H.A., U. S. Senator from New York, died June 17, in Wash-

ington, D. C. He became a member in 1918, a Charter Fellow in 1922, and a Life Member in 1936.

CONFERENCES AND DATES

American Association of Motor Vehicle Administrators. Detroit, Mich. September.

American Association of School Health. Kansas City, Mo. October 24-28.

American Association of State Registration Executives. Kansas City, Mo. October 25-28.

American Dental Association. Hotel Statler, St. Louis, Mo. October 24-28.

American Dietetic Association—21st Annual Meeting. Hotel Schroeder, Milwaukee, Wis. October 9-14.

American Federation of State, County, and Municipal Employees. Atlanta, Ga. August 29.

American Hospital Association. Dallas, Tex. September 26-30.

American Public Health Association — 67th Annual Meeting. Hotels Muehlebach, President, Kansas Citian, Kansas City, Mo. October 25-28.

American Public Works Association. New York, N. Y. October 3-5.

American Society of Civil Engineers. Rochester, N. Y. October 12-14.

American Veterinary Medical Association. New York, N. Y. July 5-9.

American Water Works Association: Central States Section. Hotel Windsor, Wheeling, W. Va. August 17-19.

Virginia Section. Hotel Robert E. Lee, Lexington, Va. August 25-26.

Rocky Mountain Section. Townsend Hotel, Casper, Wyo. September 12-13.

Michigan Section. Bancroft Hotel, Saginaw, Mich. September 14-16.

New York Section. Nelson House,

Poughkeepsie, N. Y. September 22-23.

Minnesota Section. Minneapolis, Minn. September 29-October 1.

Wisconsin Section. Milwaukee, Wis. October 10-12.

Missouri Valley Section. Hotel Fort Des Moines, Des Moines, Ia. October 13-15.

Southwest Section. Biltmore Hotel, Oklahoma City, Okla. October 17-20.

Association of Military Surgeons of the United States. Mayo Clinic, Rochester, Minn. October 13-15.

Association of Women in Public Health — 17th Annual Conference. Excelsior Springs, Mo., October 22-23; Kansas City, Mo., October 24.

California Association of Dairy and Milk Inspectors. Santa Barbara, Calif. September.

Conference of State Laboratory Directors. Kansas City, Mo. October 24.

Conference of State Sanitary Engineers. Kansas City, Mo. October 24.

Florida Public Health Association. Hollywood, Fla. December.

International Association for Identification. Columbus, Ohio. August 16-20.

International Association of Milk Sanitarians. Cleveland, Ohio. October 19-21.

International Society of Medical Health Officers. Kansas City, Mo. October 24.

Medico-Military Inactive Duty Training Unit—under auspices of the Mayo Foundation. Mayo Clinic, Rochester, Minn. October 13-15.

Michigan Public Health Association. Lansing, Mich. November 9-11.

- Mississippi Valley Conference on Tuberculosis—25th Annual. Twelve states represented. Hotel Statler, St. Louis, Mo. September 21–24.
- National Dairy Association. Columbus, Ohio. October 8–15.
- National Health Conference, called under President Roosevelt's Interdepartmental Committee to Coördinate Health and Welfare Activities—Miss Josephine Roche, Chairman. Washington, D. C. July 18–20.
- National Hospital Association (Negro). Hampton, Va. August 14–16.
- National Institute for Traffic Safety Training. University of Michigan, Ann Arbor, Mich. August 8–20.
- National Safety Council. Chicago, Ill. October 10–14.
- New England Sewage Works Association. (Joint meeting with the New York State Sewage Works Association.) Hotel Bond, Hartford, Conn. October 6–8.
- New Mexico Public Health Association. Las Vegas, N. M. October 30, 31, November 1.
- New York State Sewage Works Association—Fall Meeting (joint meeting with New England Sewage Works Association). Hotel Bond, Hartford, Conn. October 6–8.
- Northern California Public Health Association. January, 1939.
- Southern Branch, American Public Health Association—7th Annual Meeting; and Southern Medical Association. Oklahoma City, Okla. November 15–16, 1938.
- Symposium on Mental Health. Auspices of the American Association for the Advancement of Science—Section on Medical Sciences. Richmond, Va. December 27–31.
- Texas Public Health Association. San Antonio, Tex. November 7–9.
- Third International Congress for Microbiology. Waldorf-Astoria Hotel, New York, N. Y. September 2–9, 1939.
- FOREIGN
- Royal Sanitary Institute. Portsmouth, England. July 11–16.

Mercury Poisoning from the Public Health Viewpoint*

PAUL A. NEAL, M.D.

*Passed Assistant Surgeon, U. S. Public Health Service,
Washington, D. C.*

MERCURY has ranked prominently among the causes of poisoning for several hundred years. It was known to the Egyptians in 1600 B.C. The knowledge of mercury accompanied the gradual spread of Egyptian culture to Greece, and from Greece the information passed to Rome, and thence over the Roman Empire. The Egyptians, Greeks, and Romans considered mercury too toxic for medicinal use.

Mercury was known in India about 500 B.C. where its medicinal value was recognized during the 1st century A.D., and mercury stomatitis was described during this time. The medicinal knowledge of mercury spread from India to Persia, and thence to Arabia. The Arabs brought this knowledge to Africa and Spain during the Moorish conquests. The Arabs recognized the symptomatology of mercury poisoning and made more progress in its use than the Europeans of the Middle Ages.

Paracelsus, about 1525, advocated the use of mercury in treating syphilis and

also advised its oral administration. He gave the first explanation of the effect of mercury upon the body. Due to the teaching of Paracelsus, the demand for mercury increased and a larger number of workmen were employed in mining; thus, mercury poisoning among miners was common. Fallopius in his treatise on metals states that quicksilver miners rarely last 3 years in the mines. According to Ramazzini,¹ Ettmuller affirms that in 4 months in the mercury mines the miners are seized with tremblings in the joints, palsies, and vertigo, because the mercurial spirits prove highly injurious to them. In the *Transactions of the Royal Society of London*, April, 1665, is a letter sent to this society from Venice which states that in some quicksilver mines in Italy no workman is able to work over 6 hours at a time, and an account is given of one miner, who, having worked for one-half year, was so impregnated with mercury that if he held a piece of brass in his mouth, or handled it with his fingers, it became white.

Ramazzini¹ affirms that the metallic steams affect not only those who dig

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

in the mines, but all those who are employed in working, melting, and refining the metal.

At that time mercury poisoning was very common among gilders. Ramazzini describes the case of a young gilder who died from mercurial poisoning after 2 months of confinement to his bed: "the patient was of a cachectic habit of body, face wan, cadaverous complexion, eyes swollen, breathing labored, mind stupid, and the whole body seemed seized with an inactive lazy drowsiness. He had fetid breath, stinking ulcers in his mouth which voided incessantly a very great quantity of nasty matter." Ramazzini was amazed at the absence of fever during this man's illness.

INDUSTRIAL USES OF MERCURY

Apart from the widespread use of mercury in medicine, there has been a constant increase in the use of the metal in industry. Among the applications of mercury and its compounds may be cited the use of mercury nitrate in the manufacturing of felt, which dates from the 17th century.

Industrially, mercury is used in the manufacture of chemicals and scientific instruments, and for the amalgamation of gold. It is also used in the electrical industry. This wide use entails a certain hazard from exposure to vapors and dusts. Dublin and Vane² list approximately 80 occupations with exposure to mercury and its compounds.

In Table I are listed the chief indus-

TABLE I
Principal Industries with a Potential Mercury Hazard

Name		Description	Remarks	Principal Method of Entrance Into the Body
Mining	Cinnabar (HgS)	Hazard depends upon the process used; hazardous occupations are those connected with condensers, purification, flask filling, distillation repairing and cleaning	89 mines in U. S. 1933; since 1934 several new mines in U. S. have begun operations	Inhalation of vapors and dusts
	Gold	Amalgamation with mercury, closed process used at present		Inhalation of vapors
	Silver	Amalgamation with mercury		Inhalation of vapors
Chemical manufacture	Manufacture of organic and inorganic mercury compounds	Inorganic mercurous and mercuric compounds, as chlorides, nitrates, iodides, cyanides; and organic compounds such as mercurochrome, metaphen, dimethyl and diethyl mercury compounds	Inorganic compounds produced by wet and dry method; dimethyl and diethyl mercury are volatile toxic compounds	Skin, ingestion, and inhalation of vapors and dusts
	Mercury as a catalytic agent	Starting with acetylene, using salts of mercury as catalytic agent, to produce synthetic alcohols, ketones, and acids; volatile toxic organic mercury compounds also produced Sulphonation, oxidation (Kjeldahl) bromination, nitration, alkylation (Friedel and Craft)		Inhalation of vapors
	Cyanogen	Cyanide of mercury decomposes by heat liberating cyanogen and mercury; mercuric oxide plus hydrocyanic acid gives mercuric cyanide		Skin contact; Inhalation of vapors
	Chlorine	Electrolytic process—Solvay process with sodium amalgam		Inhalation of vapors

TABLE I (Cont.)
Principal Industries with a Potential Mercury Hazard

Name		Description	Remarks	Principal Method of Entrance Into the Body
Alloy Makers, including amalgam makers		Mercury forms amalgams with most metals readily. It does not form an amalgam with iron, nickel, aluminum, cobalt and platinum.		Inhalation of vapors
Electric	Standard cells Mercury switches Mercury vapor lamps Electric contacts and insulators Electrodes Accumulators Incandescent electric lamps Electric meters Electric furnaces Radio tubes	Mercurous chloride and metallic mercury Amalgamation of zinc Amalgamation of zinc Production of the vacuum, rarely used at present Sealing induction furnaces with mercury Production of vacuum by mercury		Inhalation of vapor
Manufacture of felt hats	Fur cutting	Carrotting solution composed of a solution of mercury nitrate. In the U. S. practically all employees exposed to a measurable concentration of mercury vapors	2,000 employees in U. S.	Inhalation of vapors and dusts
	Felt hat industry	From the mercury nitrate solution used in carrotting the fur, chief occupations with mercury exposure are: mixers, blowers, coners, devil operators, hardeners, sizers, starters, stiffeners	27,600 employees in this industry	Inhalation of vapors and dusts
Dentistry		Treatment by heat of mercury amalgams especially silver and copper amalgams	Dentists Dental technicians	Inhalation of vapors
Laboratories		Manipulation of mercury Spilled mercury accumulates on floors, work benches, etc.	Chemists Physicists Physicians, etc.	Inhalation of vapors Skin
Pharmaceutical		Manufacture of antiseptics, cathartics, diuretics, disinfectants, bactericidal agents, ointments and solutions containing mercury or mercury compounds, both organic and inorganic. Spilled mercury	Chemists Physicians Laboratory assistants	Inhalation of vapors and dusts
Manufacture of	Vermicides Insecticides Fungicides	Organic and inorganic compounds of mercury. HgCl_2 used in wool impregnation		Skin Inhalation of dusts
Explosives	Detonators Detonating fuses Percussion caps Pyrotechnics	Mercury fulminate in copper or brass tubes $\text{Hg}(\text{CNO})_2$ used $\text{Hg}(\text{CNS})_2$ used in Pharaoh Serpents Hg_2SO_4 used as chemical catalyst	Hamilton found 111 cases of poisoning from Hg_2 fulminate in 1916 in 28 Amer. munition factories	(Dermatitis) and Inhalation of dusts and vapors
Decoration of chinaware and porcelain		H_2O and Hg_2CrO_4 used for decorating chinaware and porcelain		Inhalation of vapors Irritation of skin
Photography		HgCl_2 and HgBr_2 used as intensifier Mercuric double rhodanide		Inhalation of vapors Absorption from skin

TABLE I (Cont.)

Principal Industries with a Potential Mercury Hazard

Name	Description	Remarks	Principal Method of Entrance Into the Body
Printing Trades	Pantone process employs a paste with mercury as a basis for cleaning silver typographic plates as well as for typographical operations. Vermilion is used in some inks. Production of printing plates. Color printing as used in linoleum		Inhalation of vapors
Battery	Dry battery manufacture; heat used in melting and soldering, volatilization of the mercury. Hg_2SO_4 used as a chemical catalyst in electric batteries Lead mercury solder		Inhalation of vapors
Paint	Mercury is a constituent of anti-fouling paints for ship bottoms. Tin-bismuth-mercury amalgam as a paint mixed with oil		Inhalation of dusts and vapors
Engraving, embossing	HgCl_2 used in etching of steel. Damascening of guns and swords $\text{Hg}(\text{NO}_3)_2$ used		Inhalation of vapors and dusts, skin
Mercury vapor boilers	A process of power generation which uses mercury instead of water in a boiler Use of mercury vapor for heat transfer in operations such as chemical reactions or distillations, as used in the petroleum industry		Inhalation of vapors
Jewelry	Production of imitation jewelry, copper gilded by the mercury process, or by plating process. Waste, debris, etc., washed and triturated in a mill with mercury, forms amalgam, then freed from Hg by heat. Metallic mercury. Heated mercury amalgams		Inhalation of vapors
Shooting galleries	Mercury vapors liberated from use of mercury fulminate percussion caps		Inhalation of vapors
Taxidermists	HgCl_2 used to treat skins for conservation Tin, lead, bismuth amalgam injection HgCl_2 Mercury very little used at present		Skin and Inhalation of vapors and dusts Dermatitis
Anatomical preparation	Mercury used in coating Mercury may occur in bronze as a contamination of tin Mercury compounds used in the preparation of hair lotions and freckle preparations Hardening tools in mercury $\text{Hg}(\text{NO}_3)_2$ in dyeing woolen goods $\text{Hg}(\text{NO}_3)_2$ in making aniline red HgCl_2 used as a mordant HgI_2 used for coloring Vermilion used as an inorganic dye Chlor-phenol-mercury and nitro-phenol-mercury HgCl_2 used in production

tries in which mercury is used, the methods and type of hazard in each industry, and the manner in which mercury may be introduced into the body. It may be seen that mercury entails exposure of a considerable number of workers and represents a public health problem of some magnitude.

TOXICITY OF MERCURY

The introduction of mercury into the body may occur by 4 routes:

1. Inhalation of vapor or finely divided dust
2. Ingestion
3. Through the skin
4. Through the subcutaneous tissues

Industrial mercurialism occurs almost exclusively from the inhalation of the vapors of mercury or the dust of mercury compounds. The oral administration of metallic mercury is toxicologically unimportant. The toxicity of most of the salts of mercury is well known. Mercury is absorbed to a slight degree through the skin by way of the hair follicles and sweat glands.

The absorption of the inorganic compounds of mercury takes place chiefly through the digestive tract. Some of the organic derivatives of mercury, as dimethyl and diethyl compounds are volatile toxic substances. In industry the absorption of mercury through the subcutaneous tissues occurs only through an accident, as when thermometer bulbs or other glass instruments containing mercury are broken and penetrate the skin.

The toxicity of mercury and mercury compounds depends upon their physical-chemical properties, as the solubility, dissociation, and volatility, as well as upon the dosage, length of exposure, route of introduction, and individual sensitivity. Mercury locally has a caustic and irritant action.

Fulminate of mercury, used in the manufacture of detonators and percussion caps, produces chronic mercurialism, and also characteristic skin and

superficial mucous membrane lesions. The skin of the majority of persons employed in mixing, drying, filling, and preparing the fulminate shows these characteristic lesions. In 1930, 20 per cent of the mercury used in the United States was in the making of fulminate.

To indicate the manner in which chronic mercurialism can occur, I will utilize a considerable amount of the data collected by the Public Health Service in a study of the hatters' fur cutting industry,³ which entailed a study of approximately 500 workers exposed to mercury vapors and dust. This publication indicates the manner in which the public health aspects of chronic mercury poisoning may be evaluated, gives the characteristic symptoms of incipient mercurialism, and its prevention.

SYMPTOMATOLOGY

The symptomatology of chronic mercurialism falls into two types, one with stomatitis, colitis, and nephritis predominating, and the other with tremor and other neurological symptoms predominating. Many authorities are of the opinion that the intestinal, buccal, and renal symptoms are evidence of acute mercurial poisoning. According to Scopoli, Merget, and Biondi,⁴ mercury compounds taken into the body through the digestive system or parenterally circulate in the body in the form of a mercury chloro-albuminate or oxy-chloro-albuminate, and cause the lesions during the excretion through the kidneys, colon, and the salivary glands. Mercury taken into the body in the form of vapor circulates as such, or in other combinations, and gives rise to the nervous symptoms, tremor, spasms, crethism, and also to emaciation and cachexia. However, both forms of poisoning may occur simultaneously.

According to Biondi,⁴ when the mercury vapors in the air are of a

higher temperature than the mucosa of the respiratory tract, the mercury is condensed upon its surface and is then not absorbed in vapor form but as a combination similar to other mercury compounds. Under these circumstances the two forms of intoxication would be mixed, for not all of the vapor would condense and some would reach the mucous membranes at a lower temperature than that of the mucosa. In that case there would develop, besides tremor, spasms, erethism, and emaciation, at least stomatitis and even colitis and nephritis. While this is an interesting hypothesis and while there is no question that the two forms of mercurialism exist from a symptomatology viewpoint, it would be interesting to prove this by experimental investigation.

In the study of mercurialism among 529 fur cutters made by the U. S. Public Health Service in 1935 and 1936, it was found that the greater part of the mercury to which fur cutters were exposed was present as vapor and that a comparatively minor part was due to mercury-impregnated dust. Forty-three cases of mercurialism were found. The most important physical impairments were fine intention tremor, psychic disturbances, exaggerated knee jerks, vasomotor disturbances, simple inflammation of the nasal mucous membranes and conjunctivae, discolored oral mucous membranes, and gingivitis. Albumin, casts, erythrocytes, and leucocytes were found with about equal frequency in the urine of mercury-affected and non-affected workers.

Gingivitis (including both pyorrhea and gum inflammation in which pus exudation was not demonstrable) was somewhat more prevalent among persons with chronic mercurialism than among those not so diagnosed. However, the incidence of gingivitis had no direct relation to the degree of mercury

exposure, and was no greater in groups with a high mercury vapor exposure (over 2.5 mg. per 10 cu.m. of air) than it was for groups with a low mercury-vapor exposure who were employed for the same length of time.

It will be noted that the symptomatology in these 43 cases was of the neurological type, the outstanding symptom being intention tremor.

THRESHOLD DOSAGE

The quantity of mercury in the air which is sufficient to cause chronic mercurialism cannot be definitely stated. Age, sex, individual susceptibility, and the physical condition of the individual play some part in determining his reaction to mercury-vapor exposure. The largest amount of mercury is eliminated in the urine, and a lesser amount in the feces. Mercury is also eliminated in the saliva, sweat, and milk. According to Gutman, the urine may show mercury for months and even years after the metal intake. According to Young, Taylor, and Merritt,⁵ during the period of active urinary excretion, the mercury is found in rather high concentrations in the muscles, bones, liver, and kidneys, but following this the muscles and kidneys show only a trace and the concentration in the bone apparently remains unchanged. They conclude that mercury is stored in the bones and to a lesser extent in the liver, and that this storage is influenced by the pH of the diet, and the administration of acids or alkalis.

Borinski,⁶ in the Berlin Department of Health, found that human beings who have never come into contact with mercury may excrete up to 1/100 mg. of mercury a day. Nearly all important foodstuffs contain traces of mercury. Individuals who work with mercury daily, as dentists, laboratory workers, etc., show daily excretion up to 1/10 mg., and the possibility of mercury

intoxication should be considered in these individuals when they complain of so-called nervous disturbances.⁶

Göthlin⁷ states that 0.4 to 1 mg. of mercury inhaled daily in the form of vapor causes chronic mercurialism. Turner⁸ states that 0.771 to 1.285 mg. of mercury absorbed daily will produce symptoms of mercurialism. Fraser⁹ found in dogs that a concentration of 1.89 mg. of mercury to 1 cu.m. of air inhaled 8 hours daily for 40 days caused no evidence of mercurialism, and that the minimum concentration of mercury leading to intoxication was 3.05 mg. to 1 cu.m. of air. The Leningrad Institute of Organization for the Protection of Labor permits only traces of mercury in the air. In the study of mercurialism among fur cutters, the Public Health Service found that the symptoms of chronic mercurialism developed among individuals working in atmospheric concentrations ranging from 0.6 to 7.2 mg. per cu.m. of air, also that the severity of chronic mercurial poisoning and the percentage of persons affected increased with the degree of exposure. The incidence of chronic mercurialism increases rapidly with increasing mercury concentration after the concentration exceeds 2.0 mg. per 10 cu.m. For instance, of the 377 persons exposed to 2.0 mg. or less per 10 cu. m. at the time of the study, 4.5 per cent were diagnosed as having chronic mercurialism, and of the 152 persons exposed to greater concentration, 17.1 per cent were so diagnosed.

DIAGNOSIS OF CHRONIC MERCURIALISM

The diagnosis of chronic mercurialism (industrial) depends upon a careful physical examination, which includes a thorough occupational history: (1) the individual's present occupation, and the length of time he has been engaged in it; (2) a record of all the occupations he has been employed in from the time he first began to work; and

(3) an estimate of the total time he was employed. The physician should know the occupations in which there is a mercury hazard. An occupational analysis by trained engineers is usually necessary in order to determine the exact occupational exposure. The industrial hygiene sections of several of the states have personnel who are prepared to make such analyses.

In the medical history, complaints of diseases of the nervous system, psychic disturbances, digestive disturbances, insomnia, loss of appetite, tremor, loss of weight, sore mouth, and weakness should be especially noted.

The following conditions should be especially noted: pallor, simple inflammation of the nasal mucous membrane, gingivitis and pyorrhea, discoloration of the mucous membranes, excessive salivary flow, dark line on the gums, stomatitis, fine intention tremor of hands, fingers, eyelids, and tongue, shaky hand-writing, speech defect, psychic irritability as shown by irascible temper, discouragement without cause, feeling of discouragement or despondency, excessive embarrassment in the presence of strangers, anxiety and excitability, exaggerated knee jerks and vasomotor disturbances such as excessive perspiration, abnormal blushing, and dermatographia.

Routine examinations should be made of the urine, looking for evidence of renal pathology. Twenty-four hour specimens of urine should be analyzed for mercury. In our fur cutting study the quantitative spectrographic method was found to be the most practical and accurate method for this analysis. The presence of mercury in the urine is not necessarily a symptom of chronic mercurialism, it can only be regarded as proof of mercury absorption.

It is hoped that in the near future a spectrographic method will be worked out for the determination of mercury in blood. A complete hematological

examination should be made; however, no one finding can be considered *per se*, as definite, positive evidence of mercurialism, as will be shown by the blood picture findings in the fur cutting industry. The erythrocyte count was slightly lower in those with chronic mercurialism than in the nonaffected individuals. Persons with the symptoms of chronic mercurialism had almost the same hemoglobin index and total leucocyte count as those who did not have these symptoms. The difference between the reticulocyte percentage of the mercury-affected and nonaffected males was 0.2370 ± 0.1074 , which was possibly, but not certainly statistically significant. The mean values for both groups were slightly higher than normal.

Other cytological data collected as stipple cell and blood platelet estimations, had little diagnostic value as far as chronic mercurialism was concerned.

The percentages of lymphocytes found in the blood of these fur cutters were slightly higher than usual and the percentages of neutrophils were correspondingly lower than usual. Although the interpretation of these differences was complicated by several circumstances which could not be controlled, it appeared that they were not necessarily the result of mercury absorption. The fact that the monocyte percentages were within normal limits substantiated this view.

PREVENTION OF INDUSTRIAL MERCURIALISM

The prevention consists primarily in the avoiding of the inhalation of mercury vapors and dusts. This is an engineering as well as a medical problem, requiring special local exhaust ventilation, good natural and mechanical ventilation, good housekeeping, and general sanitation, and in certain occupations positive pressure masks.

From a public health standpoint it is essential to determine the extent of a

hazard and to develop methods which can be employed for its control. In its study of the hatters' fur industry, the Public Health Service surveyed all of the plants in the United States, which employed approximately 2,000 persons. These workers were further analyzed according to occupation and from such preliminary data it was possible to determine the number exposed to fur which had been treated with mercury, and to determine the extent of the mercury hazard in this industry.

Following the occupational analysis, a study was made of each occupational environment and determination of the amount of mercury vapors to which the worker was exposed. It was necessary to obtain dust samples to determine the amount of mercury in this form which was inhaled. The evaluation of the industrial environment is of use in obtaining an estimate of the relative degree of mercury hazard associated with each occupation, and, where control is used, its effectiveness. In studies of the health of industrial workers the quantitative data with respect to each occupation have shown a high degree of correlation with medical findings. Quantitative estimates of the amount of contamination present in the air are also a measure of the effectiveness of control methods as Table II indicates.

From a medical viewpoint it is necessary to make periodic medical examinations of individuals exposed to a mercury hazard, paying particular attention to the symptom complex of mercurialism, as outlined.

Mild, early causes of chronic mercurialism, characterized by fine intention tremor of the hands or fingers, and slight evidence of psychic irritability, can be discovered during periodic medical examinations and the workers removed from their mercury exposure. They usually recover in a short time under symptomatic treatment, and

TABLE II

Exposure of Hatters' Fur Workers to Mercury Vapor and Treated Fur Dust Under Controlled and Uncontrolled Conditions

*Total Mercury Exposure in
Milligrams per 10 Cubic
Meters*

Occupation	Total Mercury Exposure in Milligrams per 10 Cubic Meters		Method of Control
	Uncontrolled	Controlled	
Drummers	2.5	0.6	Segregation
Clippers	1.5	0.7	"
Brushers	3.1	1.2	Local exhaust ventilation
Cutters	4.0	1.8	" " "
Sorters *	3.8	1.7	" " "
Blowers	4.6	0.7	" " "
Pilers	5.4	Trace	Good natural ventilation
Storage workers and shippers	7.2	Trace	" " "

* Depend on exhausts installed on cutting machines.

should not be returned to their old occupation until the mercury hazard has been controlled.

Patients with severe chronic mercurialism, characterized by intention tremor of a marked degree, erethism, denoted by a continuous irritability, and pronounced vasomotor changes, are completely disabled for any work, and require months of careful medical and nursing care.

It may be seen from the foregoing that the public health problem with regard to chronic mercurialism is one of preventing mercury from being ingested or inhaled by the worker. Its prevention from the engineering standpoint is one of providing a sanitary and healthful environment, and from the medical one of recognizing early

symptoms. Chronic industrial mercurialism is preventable with good engineering and medical control.

Edward Jenner Memorabilia

JENNERVILLE, Pa., was named after Dr. Edward Jenner of Berkeley, Gloucestershire, England, by Dr. Francis Allison who lived in this hamlet of Chester County between 1839 and 1859. An exhibit of portraits of Edward Jenner and other memorabilia has been in existence for years in a

brick mansion built in 1740, located on Route 1 and now known as the Red Rose Inn.

Among the exhibits is a declaration attesting the appreciation of local residents for the priceless discovery of the method of vaccination against smallpox.

The Case of Public Health vs. Public Welfare*

HOMER FOLKS, LL.D., F.A.P.H.A.

Secretary, State Charities Aid Association, New York, N. Y.

THE subject which is printed by my name is possibly a little mystifying to you, "The Case of Public Health vs. Public Welfare." It is a little mystifying to me, too, though I had a fairly clear notion of what was in my mind when I suggested it. That poverty and disease have very close interrelations of cause and effect, that we are bound to find many matters of common interest between the agencies and the persons dealing with them, is, of course, a commonplace. It has been set forth at these meetings perhaps more fully and more convincingly than ever before. Except for the period of depression we are now passing through, it has been an axiom that sickness produced more poverty than any other one cause.

The finest account of the historical development of the relations between the authorities dealing with health, public health in the sense that we use the word ordinarily, and poverty, is contained in Sir Arthur Newsholme's last book, *The Last Thirty Years in Public Health*.† About the first third of that is devoted to what is to me a very fascinating but fully clear, objectively stated, and convincing statement of what has actually occurred in Great Britain as between those two subjects,

as to important legislation, and as to administration, over the last quarter of a century.

I strongly recommend that each of you, whether health officer, social worker, or public health nurse—however you are interested in the subject—read that book.

I will not try to discuss that total general picture, because it has been done repeatedly. It is a thing that is going to be worked out in practice by actual effort rather than in the seclusion of the library or in the bill drafting departments of Congress or of state legislatures. I will speak of only a few phases of it, bringing to you a rather unassorted miscellaneous group of thoughts and comments. I am, so to speak, bringing the public welfare official and the public health official into court and putting a few questions to them.

The first thought that occurs to me is one that is familiar to many of you, no doubt. That is, that public health as an organized movement in English speaking countries is the direct outcome and the actual child of the Poor Law Administration. It is rather important, I think, to bear that in mind and to get the origins of things somewhat clear.

In 1834 there was a great wave of interest in the Poor Law in Great Britain, as you know, and one of the most classic and celebrated government

* Read at a Special Session "Public Health Today," of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

† Obtainable through the A.P.H.A. Book Service.

reports of all times, that of a Royal Commission on the Poor Law, was submitted in 1834. The main author of that report was one Mr. Edwin Chadwick, who later became Sir Edwin Chadwick, and, as sometimes happens after a thing is put over, he found himself as the executive charged with carrying out the new provisions of the new Poor Law for Great Britain, which he had outlined and mainly written.

He came at the thing from a somewhat new point of view. He was a political economist, one of the early ones, one of the fully convinced ones. Quite soon in the course of his management of the Poor Law Administration, of bringing about some coördination and some national supervision of the Poor Law Administration by local authorities, there was a great epidemic in London. There were several of them as a matter of fact, but there was one very notable one of cholera, and the only protection that was then thought of was to meet in the churches for prayer.

Sir Edwin thought more could be done than that, and he put a question (it recurred to him and it worried him) to his bosses, the Poor Law Board: "Wouldn't it be cheaper and better to restrain epidemics than to go on taking care of so many widows and orphans? Shouldn't we, the Poor Law Board, get busy on this question of preventing these recurring epidemics which cost us, for so many years after, such enormous sums of money?"

If you recall the history, the Poor Law Board, eminent people, said in substance, "Well now, you just lay off on that business that you are talking about. That is none of your affair. Our job is to take care of the poor. Somebody else has to do what is to be done, if anything can be done, about what you are talking about."

But he was a very persistent fellow. He was a cantankerous, obstinate kind

of a man who never knew when he was licked. So he kept on, and he appealed to the government of the time being to take up the question. His bosses got very angry when he went over their heads, and before long he lost his job as the executive of the Poor Law Board of Great Britain.

But his views prevailed, for about that time, in the late 1840's (the great Poor Law reform was in 1834), the government listened to him. They created, in 1848, the first national authority dealing with public health in Great Britain. Mr. Chadwick then, having lost his Poor Law job, was put in charge of the new Board of Health, created as the result of his interest and his agitation of the subject.

I wish to nail down one fact—that the proposal to establish a national health authority, though it emanated from the former chief executive of the Poor Law Board, did not propose that the new health authority should have anything particular to do with or about those who were subjects of relief in Great Britain. Quite the contrary, it was to deal with the whole community. It was going to deal with the entire population. It set out specifically to deal with the causes which produce poverty. It intended to keep other people, not then destitute, from being forced to join the ranks of the indigent. It did not contemplate any special action or provision for those who were already on relief.

Jumping from 1848 to 1937, we find ourselves, in this country, in this state, and particularly in this city, faced with the proposal that the work of the public health authority, in his efforts to prevent communicable diseases, and in the diagnosis and care of communicable diseases (and diagnosis and care are essential factors in the prevention of such diseases) should limit his services and his efforts to those persons who are indigent. This, to the

best of my knowledge, is a new proposal in public health work in this or any other country. In the light of its historical setting and, above all, in its bearing upon the future of the public health movement, it is an exceedingly serious proposal. It is by no means just a dispute about official jurisdiction over particular activities. It goes to the very root of the public health movement, its objectives, its underlying purpose, and its possibilities for public well-being. It should not be accepted without the most careful consideration.

That is the issue between public health and public relief which I wish to discuss today. I spoke of it in the title of this talk, as the case of Public Health vs. Public Welfare, because if the principles of public welfare administration, which by definition deal with the indigent, are to be extended to public health activities, then public welfare will have done public health and public well-being more serious harm than all the great benefit which it has previously contributed to the public health movement. I will state 7 considerations in support of this opinion.

1. The first point is that, as I have just shown, the new proposal is flatly contrary to the origin, spirit, and trend of the public health movement up to now.

2. The second point is that it is flatly contrary to the present program in those countries which have actually succeeded in achieving a high degree of success in dealing with a major public health problem—the control of syphilis. I refer to the report of a recent commission from this city, which investigated this subject, consisting of the Commissioner of Health of this city, a representative of the 5 County Medical Societies here, a representative of the State Medical Society, and of the U. S. Public Health Service, which states in its General Conclusions that among the facts generally believed to be the most

important in syphilis control in the Scandinavian countries and in Great Britain is “the fact that in all of these countries diagnosis and treatment are free, accessible, and generally good.” The commission adds, “In all these countries diagnosis and treatment are free to all without economic distinction.” In entering for the first time upon a really concerted nation-wide movement to control syphilis, would it not be indefensible to ignore and, in fact, to proceed directly counter to, a principle which, in the opinion of such authorities, has been of prime importance in the notable success secured in these 4 countries.

3. My third point is that to limit the scope of the public health authority to indigents would be a departure from the practice of every department of municipal government, except only that department which has been specifically created to deal with indigents. It is possible to talk so much about the indigents as to gain an impression that public services generally are for the special benefit of the indigent. Nothing could be further from the case. Public services, almost without exception, are for the benefit of the entire public, and deal with the people as a whole, and as individuals, without reference to their economic status. These public services could have been set up conceivably upon a different basis; but they were not, and no one, so far as I know, has proposed that they should be. Take a look for a moment at a few of the major services of a municipality.

There is the fire department. If my house takes fire, I send a call to the fire department, and it very promptly comes to my rescue. The fireman is a curious type of person. He has a single track mind and is dominated by only one idea. When he arrives, he does not say “Good morning” and chat with me and my family for a few minutes, to cultivate useful contacts for the future.

He asks only one question—"Where is the fire?" His manners are bad; he is terribly direct in his approach; he runs all over my place with his muddy boots; he takes his muddy hose up the stairway and chops through the side of the wall, or into the roof. He does anything and everything, regardless, in order to get water on the fire at the right time, in the right place, and enough of it to put the fire out. But he is a great success in putting out fires. I have sometimes thought it would be a good thing if all health officers, before they were appointed, were required for a couple of weeks to ride the fire engine, and see how the fireman tackles his job—for fires also are catching. Fires can be put out by water, but it requires skill to get water to the right place, at the right time, and enough of it. Syphilis can be put out with arsenic and bismuth, but they must be applied in the right place at the right time, and in the right amounts. The important thing is the result, not the economic status of the person having the communicable fire or disease. But fires are all the fireman is concerned with. He does not stop a minute when I send the call, or when he arrives, or while he is putting the fire out, to ask whether I will be able to pay for his service. Of course I probably could pay for it, if the city should send me a bill. As a matter of fact, I do pay my share of putting out all the fires in the city whether my own house takes fire or not. Each year my tax bill includes my share as a taxpayer of the cost of putting out fires, but the service is free to any and all when the fire gong rings.

The police of my city watch over my house when I am away for the summer, or at any other time. They take a look at it nearly every day. When I return, unless I think to notify them, I am only in my house for a very few hours before the policeman knocks at the door to see if I am home, or

whether some person has broken in. The police department never sends me any bill for these services. I could pay for it directly, but I pay for my share of it in the tax bill, as does every other resident of the city. I am not expected to hire a private watchman of my own, though possibly I might be able to do so. That is not the way public service is organized.

The park and playgrounds of this city, and of every city, are open to all comers. There are no parks and playgrounds set aside for the indigent, for their particular use and benefit. Nobody inquires as to how many of the people using the parks and playgrounds could pay for that privilege.

Public housing provision has been a very active subject in the last few years. The federal government, the individual states, and the municipalities, by one plan or another, have built many apartment houses, or individual houses in groups. No one, I think, has had the hardihood to suggest that any one of these provisions should be set apart for the indigent only. It is difficult to think of a suggestion which would be more generally unpopular. They are for persons of limited income to be sure, but that is a very much larger group. They may be occupied in part by people who receive relief money, from which the rent is paid, but never exclusively by such persons.

There was once, in 1820 in New York State, a suggestion that all those receiving public relief should be brought together in one housing provision in each municipality, or county. It was maintained that the indigent would receive better care; that children would be better trained: they could more readily be provided with work. It sounded good. Such a law was passed. Logically, this common housing of the indigent was called "a poor house." Its history is known to all. Its development was the most outstanding failure

of any public enterprise ever undertaken. The indigent do not wish to be grouped together. They bring to each other only humiliation and despair.

Education, of course, is the great outstanding instance of a public service, open to all, availed of by practically everybody, and paid for by those able to pay and in proportion to their ability to pay.

As public health workers, we should hesitate long before accepting for the public health authority a completely different basis of administration and action from that of practically all other municipal departments.

4. My fourth point is that a public health service for indigents would inevitably fail to attract any considerable public interest, or to be granted any considerable private or public support. This is, in fact, a matter of great moment. The public health authority has been given legal powers quite beyond those of any other department, and public funds to meet any emergency, *because* it is generally understood to be protecting the health of *all* the people. What a different appeal any health agency would be making if it were clear that it would deal only with indigency. How far, for instance, would a National Association for the Study and Prevention of Tuberculosis among Indigents have gotten as compared with the tremendous organization and great resources of the National Tuberculosis Association for everybody? What would an American Association for the Health of Indigent Children have been able to accomplish? How far would Col. Snow have been able to get if he had established an American Association for Social Hygiene among Indigents? How far would *any* public health department get if it were in name and in fact a department for the protection of the health of the indigent? It would have no appeal to the imagination; it would speedily reach

the status to which it would be entitled, and to which it would properly belong, that of a medical bureau in the Department of Public Welfare.

5. My fifth objection to limiting any public health service to the indigent is that, speaking broadly, there is no such group. There are a great many people who were indigent yesterday, but are self-supporting today, even though they may be indigent again tomorrow. The rapid turnover of the relief rolls all through the depression has been one of its chief characteristics. People are on and off the relief rolls, and on and off again, as the changing tide of employment or of good fortune may affect them. Over a period of years, there are enormous variations in the number of the indigent, using that term in its ordinary sense. In 1929, there were no public indigents, and only a few private indigents, in New York City. Four years later 20 per cent of the population were indigent. The percentage has wide swings up and down. No health program can be built on such a shifting basis. Both tuberculosis and syphilis require long-term planning and long-term care. The shifting of the individual patient to and from the status of indigency has no conceivable relation to the care he needs, and, above all, no relation to the steps that need to be taken in relation to him, to prevent other people from being infected by him.

But apart from the shifts in the ranks of the needy, there is no generally accepted test as to what constitutes indigency. Is an old age security allowance, though based on need, a form of indigency? Is a so-called extended unemployment benefit, though based on need, a proof of indigency? Are widows' pensions, though granted on a relief basis, for the indigent? You might think so, but we are spending hundreds of millions of dollars each year in these United States to prove the contrary,

and the people believe the contrary.

On the other hand, it is even more true that huge numbers, millions in fact, of those whom we call non-indigent and self-supporting, are not in truth, and in reality, self-supporting. They are not supported in any fair sense of the word, either by themselves or by anybody else. Their standard of living is so desperately low that they do not really support themselves, they merely continue to exist in a poor dying way. Truly, they need health provision desperately, but they are not in the ranks of the indigent; they are not on the relief rolls. No one can look at these fundamental facts about the economic status of the people of America without realizing that there is no basis for a public health program anywhere, at any time, in attempting to draw a distinction between the indigent and the non-indigent.

6. For my sixth point, let us push this thought one stage further. Dr. Lee K. Frankel, a true statesman in social welfare and public health, and a great leader in this American Public Health Association just 10 years ago, stated on several occasions that unless conditions changed, the end of poverty and of the need of relief was in sight. He said that the great family welfare societies of New York City, would be able within a few years, unless trends changed, to devote all their funds and all their efforts to providing education, recreation, and generally a higher standard of living among those with low incomes, for there would be no further occasion for material relief. He was speaking primarily of the people of this city. Of course, conditions *did* change, and his prophecy seems now somewhat grotesque. It would be a great mistake, however, to think that he was not fundamentally justified in 1927. In fact, I have no considerable doubt that the attainment of what he foresaw then, a few years ago, has been simply post-

poned and by no means abandoned. I think we have arrived at an American policy in regard to poverty. It consists of two major elements: (1) the preventable causes of poverty will be prevented; (2) non-preventable poverty will be called something else, and dealt with by different methods and on a different basis.

I say all this to raise the underlying health question. If there should be no indigency in a few years, will there be no need for public health and no health authority? The question answers itself. It is inconceivable that we should not have a stronger and a more efficient public health authority under such circumstances. We could afford to do more for health, and there are endless areas to be covered, innumerable things to be done, before we have prevented all preventable illness.

7. My seventh point is that the methods and objectives of public health and of public relief are different fundamentally and also from the point of view of the psychology of the public, and are wholly incompatible with any identification of the two subjects. Poverty is something which everyone dreads, everyone seeks to avoid, every welfare authority seeks to limit, in the area of its application. Poverty is excessively unpopular. The public mind is set against it. Those on relief naturally and properly make every effort to conceal the fact. Health, on the other hand, is something which everyone desires and desires more strongly than anything else. It is a goal toward which everyone strives. It is cherished next to life itself, and occasionally even life seems undesirable without health. Health promotion takes on wider vistas with every new scientific discovery. Public health seeks to make available that ever increasing area of health facilities which the individual cannot afford, and that area of protection the individual cannot provide for himself. Yoked to

indigency, health would be on the way out. Anchored to the community as a whole, health is on the way in.

RELIEF AND HEALTH

For these seven reasons, then (and there are plenty of others), it is apparent to me that relief and health, although on the same highway, are moving in opposite directions. The more efficient either or both of them become, the farther apart they are. The destination of one is universality; the destination of the other is disappearance. These destinations are as far apart as East and West, and "East is East, and West is West, and never the twain shall meet."

PREVENTIVE MEDICINE

It is implied in what I have said that I am dealing with public health in the older and more limited sense of *preventive* medicine. I deem that an exceedingly important point, and I hold the position that it is not only possible but exceedingly important, not to get preventive public health confused with the whole question of medical care.

Sir Arthur Newsholme¹ in his paper a day or two ago—and he is the man from whom I have learned more about public health than from anybody else—referred to preventive medicine and clinical medicine as being Siamese twins. Even Sir Arthur might be mistaken once, you know. I hope he is mistaken, for I have always felt that to be a Siamese twin was one of the least desirable of all possible modes of living.

In the first place, twins are apt to be much alike, physically, mentally, and emotionally. You expect twins to be alike. But public health organization is very different in many respects from the practice of medicine. For one thing, the public health official wears peace-

fully, or even proudly, the badge of public office—of serving the whole community, as part of the government, of fighting disease wherever it is, and not only in some selected sector.

On the other hand, you all know that if you are in a medical society, you must be very careful about mentioning government at all, because there might be explosions, mishaps, and other unforeseen things like that. In other words, there are reactions, emotional, mental, and temperamental, which are very different. So they can't be twins—clinical and preventive medicine. That is, they don't look alike, and they don't act alike, and they don't think alike.

A second thing is, I think, conclusive. Twins have to be born at about the same time. There can be a little lag, I believe, between twins—as to the hour of birth—but it can't be very long. Sir Arthur said that the public health movement was a little less than 100 years old; the practice of medicine, as you all know, began around 400 B.C. You could not have a lag of 2,200 years between the birth of twins, could you?

So, I prefer to see these two great services, for the present and for some time to come, one chiefly governmental and one chiefly individual, each established on its own feet, without trying to act like twins; each having its own normal development, each serving its purpose, each accumulating its own experience, each adjusting itself to the needs of the community from time to time. I do not want to see at this time any attempt to merge things that are as different as public health, a governmental service, and the private practice of medicine. That may come in the future, but not yet, nor soon.

The Health Department in the Field of Medicine

From the Standpoint of a Private Practitioner*

CHARLES H. GOODRICH, M.D.

President, Medical Society, State of New York, Brooklyn, N. Y.

THE potentialities of preventive medicine have developed almost as amazingly in the past few decades as have medical diagnosis, surgical technique, and endocrinology. This as a part of the daily, commonplace realization of medical health department workers. To the rank and file of practicing physicians these potentialities are dreams, imponderables. When we first suggested an aggressive program to incite interest and undertaking in preventive medicine, an eminent metropolitan surgeon with an unusually broad knowledge of medicine in general remarked "There is little we can do about it for it is summed up in the use of a few specific vaccines and serums." Per contra, health department workers are almost as astonished as are newspaper editors when they hear of medical cures or successful surgical operations which are ordinary occurrences in medical practice. We do not understand each other well enough to benefit our people with an adequacy of service comparable with our conjoined abilities in a state of fusion.

Theodore Roosevelt once said "'Together' is the grandest word in the

English language." Mutual understanding and endeavor are resultant implications and should be translated into accomplishments. To do this we must be frank with each other. We know intimately a married pair who seldom have impatient words with one another, but when the servants irritate and disturb the wife, she relates eloquently to the husband their shortcomings, mistakes, or impertinences. He has, after patient listening, uttered the stereotyped kindly response "What good will it do to scold me? Why not tell *them* about it?" In kind, when we have shortcomings tell *us* about it—not your associates. We are learning to tell you when policies or actions seem shortsighted, ineffectual, or unjust, and are instructed and gratified with the courtesy and coöperation in your response.

During the meeting of the Sixth District Branch in Owego on September 21 the presidential address was captioned "Preventive Medicine and Tuberculosis." Therein we indulged in the following fantasy—"In organizing a renewal of the campaign for the prevention of early tuberculosis compare our 'man-power' to that of a foot-ball team. The health departments, financed and directed by the state and local governments, furnish the runners who cover much ground, the

* Read before the Health Officers Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1932.

half-backs and full-backs, and the quarter-back who calls the signals. What can they do against the 5,000 year old tubercle bacilli deployed all over the field, without a strong scrimmage line? With the general practitioner as center-rush, roentgenologists as guards, surgeons at tackle, and specialists on the ends, we may have some chance of winning. Hearty coöperation is therefore most desirable." This illustrates our dream of coöperation in this line of work.

Physicians think that health department officials and doctors of public health who have regular hours, 9 to 4, or 9 to 5, good salaries, offices and equipment furnished, and with no professional expenses, proceed to undermine the practitioner of medicine who has long hours, irregular sleep, often broken or abolished for 24 to 48 hours, no salary, often large earnings with heavy expense and scanty collections. They believe public health doctors do not see anything of many dangers hanging over the people and pay no attention to physicians' warnings. They have a close view of illness and prevention and a close view of tragic happenings.

Public health doctors think—physicians roll around town luxuriously making largely social calls for large fees, really do little work, have no interest or patience with health department matters, especially those most important affairs in which health departments dominate but need physicians' coöperation. They lack adequate appreciation of the great work of the great mass of physicians and surgeons. Theirs is an aeroplane view of disease and prevention with little or no personal experience with tragedies of life except as read through collected and carefully arrayed statistics.

When we realize how few practising physicians attend a convention like this or conferences of health officers, and how few health officials are regular

attendants at their county medical society, state society, or national meetings, we comprehend that in general the scope of vision in matters mutual are naturally restricted. However, there are bright spots which we can consider as exceptional and happy examples of what can happen. The secretary of the Medical Society of the State of Kentucky is the State Commissioner of Health. It is evident that your Association regards this ambidextrous gentleman with approval for you have selected him as your next President. In Alabama the State Medical Society *is* the Health Department and selects the Commissioner. Any one who has had the privilege of knowing and appreciating the qualifications and accomplishments of the present Commissioner of Health in Alabama will join us in felicitating that state upon its health arrangements. Undoubtedly health departments, under the present magnification of party politics, cannot always be under such ideal direction; for lay government is not infallible in its knowledge of scientific qualifications. In New York State and in New York City we have been and are now most fortunate.

Locally if a health officer *is* an active member of his county society and in frequent conference with its officers and committees, health matters proceed with notable satisfaction. We have discovered several such localities in our official visits to districts in this state. Where the health department and the county society each "goes it alone" separately in health matters, both grumble more or less about the conduct of the other. They should work together. Objectives are identical—why not coöperation?

In order to fulfil our obligations upon this program we are supposed to discover some of the "encroachments on medical practice" by health departments. If we were narrow enough to

define the word "encroachment" with meticulous accuracy we could say that nearly all health department activities are encroachments. However, as we recognize that "generally accepted custom makes law" (as well as language), and as physicians of the past have approved of the building up of the health departments' provisions in mass preventive medicine and custodial care, we inherit these regulations, with gratitude for the efficiency which has been demonstrated. As physicians we wonder if this efficiency would not be enlarged if our coöperation were habitually sought before plans are made and activities started, as has been notably the case in this state in the programs for controlling syphilis and pneumonia.

Some encroachments exist which are largely sporadic and local or personal, usually with the complete innocence or ignorance of clear principles by the subordinate officer in charge. An example far from here:

A health officer who is also a school inspector referred so many children with a certain type of ailment to physicians and consultants of his state department for *treatment*, that the people of that community came to believe that this was the best way to have such cases managed and, regardless of the capacity of parents to pay, demanded that their children have the same free care. When it was called to his attention by local physicians he said he was helpless—that the people demanded it, and he dare not change else he would lose his position.

In general, we believe that whatever may rightly be called encroachments upon medical practice are largely due to the limited knowledge of the majority of practitioners concerning the technique of disease prevention (except in specific prevention, as in smallpox, diphtheria, typhoid, tetanus, etc.), balanced by the limited appreciation of health officers and associates of how

earnestly and devotedly physicians in general work for their people. The remedies: For the general practitioner, awaken his interest and train him in preventive medicine. For the health officer, advise him to join and work in his county, state and national medical societies so that he will understand the spirit of practising physicians and, combining their viewpoint with his own, become more useful and accomplished. In other words, develop more McCormacks and Bakers.

We believe that centralized clinics for the administering of specific remedies for prevention and for other preventive activities could wisely be replaced by sending this work to physicians' offices with payments for the physicians, on condition that the county medical society members accept guidance by the department, as in the Detroit plan. Some say this is more expensive. It is; but it would recompense the community to have every physician beneficently compelled to interest himself in prevention, whereas, the multiplication of centralized clinics tends to cause an increasing atrophy of interest on the part of physicians. It is the social effect upon them and the community that reduces the proper advantage to the community that is far more important than the small returns in dollars. As in remedial services to the indigent, the community by paying the physicians for care of the indigent will be commensurately rewarded, for, as has been wisely remarked by F. E. Elliott:

"Every community has a vital stake or resource in the financial prosperity of its physicians." They must not occupy their minds with worries about how to exist and support their families.

Surely, as our great Surgeon General has said, "The taxpayers will determine how much they will pay for health service."

The taxpayers *can* be made to under-

stand the need of greater appropriations for health work. Henry Vaughan has done it, and it should be accomplished everywhere not only for the purposes above mentioned, but also because the salaries of physicians who are health department officials are grossly inadequate, when we consider the required time given to preparation and training. The health department of a city is quite as important as the fire department; yet we are informed by credible authority that the mere change of the firemen in this city to a 3 platoon system involves a larger expenditure per year than the *entire* appropriation for the health department. You can rebuild burned houses! Should we watch undisturbed the destruction of human lives because of scrimping appropriations?

In general we believe that *treatment* of all conditions, when patients are not under custodial care by governments, should be referred to private physicians. For instance, competitive treatment clinics should be avoided in venereal disease work. Diagnostic clinics? Yes! Treatment—No! As soon as the state or community takes this over many physicians are not interested, and the physician's office is the look-out station for such cases. In the current war on syphilis inaugurated by Surgeon General Parran while Health Commissioner in New York State with the coöperation of the State Medical Society, every possible effort to comply with this principle is made. However, it would be a wise provision in such instances to have all physicians so treating such cases qualified by their county society and made amenable to regulations made by the county society and the department. In other words, not every physician is trained and qualified to treat syphilis efficiently. If this work is to be distributed, only trained and qualified men should be utilized. The approved roentgenologists should

be generally used in X-ray case finding in tuberculosis and their services available daily throughout the year. The occasional spasmodic attacks by various health organizations using commercial laboratories or technicians is entirely inadequate. Health department diagnostic clinics for the indigent, and in rounding up of contacts, are of course necessary in many areas, and we understand that competent roentgenologists are the interpreters and consultants. The best talent we have is none too good or too expensive in this service.

State subsidized laboratories of pathology, bacteriology, and serology are reputed to be providing unfair competition for private laboratories in that gratuitous services are given to those competent to pay, or substandard fees are charged. The contention that such laboratories should adhere to charges mutually agreed upon in non-indigents seems reasonable. Some prominent gifted laboratory directors feel that there is great danger to private practitioners along this line, and great disheartening of young practitioners. We quote one of these:

"From my own viewpoint as director of a private clinical pathological laboratory, I can assert that the State Department of Health, through the State Laboratory and State Subsidized County Laboratories, offers most unfair competition. They are eager to furnish free laboratory service to any patient when requested by a private practicing physician or surgeon. Here the latter are short-sighted because every time they call a State Health Department man in and secure free consultation service, they are aiding in the destruction of the practice of private clinical pathology. If they succeed in destroying this branch of medicine as a private enterprise, they will next try to take over medicine and surgery (which they are already doing in certain areas). They will ultimately reach their goal of obtaining complete control of medical practice by destroying all private practice. We can then look back at events that have happened and thank ourselves for supporting their endeavors."

This physician is a fine citizen and a medical leader in his section and his state. Can we disregard his expressed opinion? We know that with present appropriations control of all medical practice in his state would not be possible. However, he has had some discouraging experiences and we hope that he has already conferred on the laboratory matter.

We need more constructive mutual thought and coöperation, and our urging that "Every practising physician should be a deputy health officer," means just what it said and *was* unanimously approved by the State Medical Society. In this action we are pleased to offer our opinions, our counsel, and our services to health authorities. We believe that this can be duplicated in all states if the genuine desire for service to the people pervades practitioners and health department groups.

We must agree that maximum efficiency in health matters must prevail. Working together is the accepted formula therefore hereabouts.

We believe that periodic health examinations of the apparently well person is the heart of the preventive medicine which falls to the duty of practitioners. There is meager demand for it by the public. Health departments with their many contacts extending out into the realm of the visiting nurses and the child welfare stations can do wonders toward enthusing the public over this regular inspection and record. We believe accurate permanent records are essential to ultimate ideal success. Ward Crampton believes that a hundred years from now each candidate for periodic health examination should be able to lay before his examiner the records of his great grandparents. Is this such an idle dream? Think of the disabilities and lives saved all along the century! We can all assure the people that such complete examination will be competent insurance against

a definite proportion of prevalent diseases which are sneaking up behind them unnoticed or their *apparently* trifling symptoms disregarded. Or, as in cancer, where the duration of the growth is often in doubt, patient and physician can be sure that its inception dates from some time after the last periodic examination record.

This is one way in which you may help us to prevent disease with the use of forces and people at your command.

Tell us how we can help you! We realize that the license to practise medicine implies other obligations than the diagnosis and treatment of disease. I would not be here today if this were not true. With the knowledge the state has proved we possess, we should not be merely the audience when the play "Prevention" is staged. Tell us how we can help you! Integrate us into your systems wherever it is possible, remembering and asking taxpayers to remember, that the majority of practising physicians live on a smaller income than the average of the inadequate salaries of health department physicians—and the majority of these physicians deliver first class service in stout-hearted self-sacrificing spirit without regard to hours or convenience.

Here, as elsewhere, there is strength added in union of efforts and "Together" should be our motto.

There is one final point which must be frankly disposed of. Health departments, welfare agencies, and other public health organizations, on the one hand, and the medical profession on the other, all contain a certain very moderate percentage of self-seeking, narrow-minded, thoroughly commercial persons, whose expressed views are based in reality on expectations of dollars and cents return to themselves, not on the welfare of the people. Some of them have subsisted for years on the golden products of superheated volubility interspersing a few facts charred beyond

recognition. Those in the public health group decry the medical profession and all its works thinking to make more places and salaries for themselves, climbing by pulling the other fellow down. Their most violent criticism of a physician's opinions is "He went medical." That in their estimate is the lowest depths of moral degradation. The physicians' group referred to claim that public health workers interfere with their practices; regulations make things hard for them; they steal their work; their money; lessen disease; and hurt their practices.

For these groups, who misrepresent health departments, other public health organizations, and practising physicians, and disgrace themselves, we must turn aside and do some missionary work,

educate them out of their gilt-lined rut, especially those who are destructively vocal. To physicians we can easily demonstrate that the more diligently and faithfully and unselfishly we work for others the greater the emolument—depending of course somewhat upon the chosen field for work and upon the way the word "emolument" is defined. We dare to presume that it is much the same with the comparable successes of health workers. Worth is acknowledged proportionately if not adequately. If we are not successful in our efforts at reformation, how about giving these black sheep a very icy shoulder and studied inattention on all occasions when they are "looking for something good." They do not belong in our ranks.

Prevention of Stream Pollution

IN the iron and steel industry an outstanding problem is to prevent stream pollution by waste liquors from such operations as pickling, in which metal is commonly acid-treated. This industry, after endeavoring to solve this problem for many years at heavy expense, has recently founded, through the American Iron and Steel Institute, a fellowship at Mellon Institute of Industrial Research, in Pittsburgh, with the aim of acquiring novel ideas and attempting a definite solution. This investigation will be carried on until concluded to the satisfaction of health

and industrial authorities. It will be the objective to treat or process the waste liquor of pickling plants so as to render it entirely safe for discharging into streams, recovering from it chemicals from which useful products can be made economically.

Willard W. Hodge, professor of chemical engineering and head of the Department of Chemical Engineering at West Virginia University, and also director of the Engineering Experiment Station of that institution, has been granted a year's leave of absence to head the investigational work.

Chloramine Treatment of Sea Water*

LEWIS V. CARPENTER, F.A.P.H.A., LLOYD R. SETTER, AND
MORRIS WEINBERG

*Professor of Sanitary Engineering; Instructor in Sanitary Engineering;
Research Chemist; New York University, New York, N. Y.*

CHLORAMINE treatment has been tried for sterilization of salt water swimming pools along the Atlantic seaboard to eliminate the complaints of patrons concerning the irritation of the throat and eyes by chlorine. These studies were started because of the uncertainty of the effectiveness of chlorine when using salt water with a pH of about 8.0. The following procedure was adopted as the most practical approach to the problem of swimming pool disinfection when the contamination occurs in the presence of the disinfectant.

To a series of 250 ml. clear glass stoppered bottles containing 100 ml. of sea water at laboratory temperature was added a variable quantity of ammonium chloride and a measured quantity of chlorine water. After 3 hours of ammonia and chlorine treatment, 10 ml. of each sample was removed for a residual chlorine test.

The residual sample in each bottle was then inoculated (contaminated) with exactly 2 ml. of cotton filtered raw sewage. After 2, 5, 15, and 30 minutes contact of the sewage with the treated sea water solution, 10 ml. was transferred with a sterile pipette to a sterile test tube containing a small crystal of

sodium thiosulphate. Duplicate nutrient agar (Bacto-Difco) plates were immediately prepared from decimal geometric tap water dilutions of the thiosulphate treated aliquots. Using a Lumi-lens magnifier, the bacterial colonies were counted after 24 hours' incubation at 37° C. Residual chlorine was determined by the orthotolidine method immediately prior to, and 15 minutes after, sewage inoculation.

RESULTS

The sea water used in the disinfection studies was obtained from Rockaway, N. Y., off a jetty opposite Beach 19th Street. The more pertinent chemical analyses of the sea water are as follows:

Total Solids	35,708 p.p.m.
Calcium	503 p.p.m.
Magnesium	1.185 p.p.m.
Total Iron	0.36 p.p.m.
Chlorides	17,640 p.p.m.
Kjeldahl Nitrogen	0.144 p.p.m.
Ammonia-Nitrogen	0.07 p.p.m.
Nitrite-Nitrogen	0.0002 p.p.m.
Alkalinity (as CaCO ₃)	108 p.p.m.

The pH of the sea water was found to be 7.9 electrometrically (Hellige glass electrode apparatus) and 8.0 colorimetrically (uncorrected for the salt effect). Chlorination, equivalent to 1.5 mg. per liter in the presence of zero and 3.0 mg. NH₄Cl-N per liter, had no effect on the colorimetric pH reading.

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

Of 21 series of experiments using a constant dose of chlorine and a variable concentration of ammonia, 8 are presented as representative.

The desk data were analyzed by plotting the logarithm of numbers surviving against time. In cases where less than two organisms survived per ml., it was assumed that the survival was one organism per ml. or one organism per plate. Generally a smooth curve could be drawn connecting all points. In a few instances where a single determination was an obvious error a correction was made.

The original number of organisms present at zero time in a series was obtained by extrapolation of the sea water disinfection curve (the blank). Using the above value as 100 per cent, the percentage survival of organism was tabulated.

In 4 series the chlorine dose was 1.2 p.p.m., and the residual chlorine content at the end of 3 hr. was substantially the same for samples of equal ammoniation. Arithmetic averages of comparable treatments for both residual chlorine tests and the percentage survival of organisms were made and

plotted on a semi-logarithmic scale in Figure I. The curves show the survival of organisms in percentage, for disinfection periods of from zero to 30 min.

The ammonium chloride treatment is indicated on each curve by the ratio of ammonia nitrogen added to chlorine dose. The average residual chlorine values prior to bacterial inoculation and after 15 minutes of disinfection are also indicated.

The curves show:

1. Sea water itself caused a fairly rapid death rate of sewage organisms. An average of 21.2 per cent survive after 30 min.
2. Sea water chlorination equal to 1.2 p.p.m. without ammoniation caused an increased rate of disinfection (an average of 0.35 per cent survival after 30 min. disinfection).
3. Pre-ammoniation equal to $\frac{1}{4}$ to $\frac{1}{2}$ the chlorine dose of 1.2 p.p.m. was far less efficient than chlorination alone (5.6 and 2.8 per cent) survival in 30 min. for N:Cl₂ ratio of 0.25 and 0.5 respectively. Furthermore, after 5 min. of disinfection, the death proceeded at a rate very similar to that obtained from sea water alone.
4. Pre-ammoniation equal to and twice the chlorine dose gave a disinfection rate similar to chlorination alone (0.20 and 0.55 per cent) survival after 30 min. with a N:Cl ratio of 1.0 and 2.0 respectively.
5. Pre-ammoniation to N:Cl ratios less than 1.0 apparently causes a greater consumption of chlorine than non-ammoniated sea water or ammoniation to N:Cl₂ ratios of 1.0 or greater.

In 4 series of experiments the chlorine dose was 1.4 p.p.m. in 2 series and 1.6 p.p.m. in 2 others. Slight differences in results between the higher and lower dosages were considered insignificant and the 4 series were averaged together. The curves showing the percentage survival of organisms against time of disinfection with an average chlorine dose of 1.5 p.p.m. are presented in Figure II. The curves indicate that disinfection proceeds similarly, but at a more rapid rate than with the 1.2 p.p.m. chlorine dose except for ammonia-

FIGURE I—The relation between the survival of organisms during disinfection with a dose of 1.2 p.p.m. Cl₂ made 3 hours prior to bacterial contamination.

FIGURE II—The relation between the survival of organisms during disinfection with a dose of 1.5 p.p.m. Cl_2 made 3 hours prior to bacterial contamination.

chlorinated ratios less than 1.0. Chlorination alone gave a survival of less than 0.015 per cent in 30 min. Ammonia-chlorination ratios of 2, 3, 4 gave practically the same bacterial kill in 30 min. as did chlorination, although the initial rate of disinfection was less rapid.

The relation between bacterial death rate and residual chlorine can be more clearly presented in Figure III where the percentage survival of organisms in 15 min. is plotted logarithmically against the chlorine residuals in p.p.m. at the beginning and end of the 15 min. disinfection period. The right extremity of each bar represents the chlorine residual at the beginning of disinfection and the left hand extremity the chlorine residual after 15 min. A diagonal line was drawn from a point indicating the average survival in the absence of chlorination to the midpoint of the lower left hand bar in which the ammonia-nitrogen to chlorine ratio was 4.0.

This arbitrary index line shows a fairly definite trend that the 15 min. death rate of chlorine disinfection, with or without ammonia, practically doubles with each 0.1 p.p.m. increase in the mean residual chlorine during disinfection, more or less independent of the ammonia dose and that a mean residual chlorine during disinfection of 0.27 p.p.m. will give an average kill of 99.9 per cent of organisms.

The major drop in residual chlorine of ammoniated sea water with $\text{N}:\text{Cl}_2$ ratios below 1.0 over that of the chlorinated sample during the 3 hours prior to sewage inoculation was of sufficient interest to warrant further investigations. Eleven additional series of tests were made in which residual chlorine was obtained at frequent intervals over a 3 to 6 hour period. After chlorine-ammonia treatment in the absence of direct sunlight at laboratory temperature a typical series is presented in

FIGURE III—Relation between bacterial death rates, residual chlorine at the beginning and after minutes of disinfection for different ammonia-nitrogen to chlorine ratios with a chlorine dose of 1.2 p.p.m.

FIGURE IV—Effect of ammonia chlorination of sea water on orthotolidine residuals

Figure IV in which sea water samples containing varying quantities of nitrogen as ammonium chloride were treated with 1.5 p.p.m. chlorine water, and after a 200 min. contact period the samples received an additional dose of 0.75 p.p.m. chlorine. The residual chlorine values are plotted against the time of treatment.

A rapid reduction of residual chlorine occurred in all samples. The rate of residual chlorine reduction was least in samples containing no added ammonia and greatest in samples ammoniated to a slight degree, *i.e.*, 0.5 p.p.m., ammonia nitrogen. Two-thirds of the chlorine dose was dissipated after 5, 20, and 40 min. for nitrogen added to chlorine added ratios of 0.33, 2.0, and 0.0 respectively during the first treatment. After a low residual chlorine tension of less than 0.5 p.p.m. was reached the rate of chlorine reduction materially decreased. Rechlorination of the samples after 200 min. treatment produced results showing again a rapid dissipation

of the chlorine very similar to the first treatment.

Preliminary tests indicated an increase in the dissolved oxygen content of ammonia-chlorinated sea water. Apparently low ammonium nitrogen values in the presence of sea water chemicals results in a greater decomposition or break-down of the chlorinous compounds than ammonia-chlorination to high nitrogen to chlorine ratios or chlorination without ammoniation.

DISCUSSION

Disinfection studies of sea water by means of the chlorine ammonia process were conducted to simulate conditions of salt water swimming pool bacterial control. It was assumed that the salt water would be recirculated and that the clarified return water would be chlorinated to maintain a residual chlorine content in the pool to disinfect sporadic bacterial contamination efficiently.

It was observed that chlorine dose

was rapidly depleted. The reduction of chlorine could not be accounted for by the "chlorine demand" of the unpolluted sea water. The rate of break-down of residual chlorine appeared almost equally rapid in the dark as in the presence of diffused daylight at laboratory temperatures.

Chlorination in the presence of an ammonia-nitrogen dose equal to less than, roughly, twice the chlorine dose resulted in a more rapid dissipation of residual chlorine than chlorination without ammonia or ammonia-chlorine treatment to ratios greater than 2.0.

The rapid break-down of chlorine in the presence of small amounts of ammonia nitrogen bears a rather important relation to practical salt water swimming pool control where the ammonia nitrogen in a recirculating system will accumulate due to hydrolysis of urea. It may be advantageous to ammoniate initially and maintain a rather high ammonia content. It is of interest to note at this point that in the disinfection studies the ratio of ammonia nitrogen present to chlorine residual *at the beginning of a disinfection period* exceeded 15 to 1 in all ammoniated samples.

The more rapid break-down or dissipation of residual chlorine in the presence of small amounts of ammonia was observed by Gerstein² on Lake Michigan water. The accentuated break-down was not so great as in sea water and the greatest effect was found at somewhat lower ammonia to chlorine ratios. The fact that an abnormal break-down of chlorine did not occur in distilled water led Gerstein to attribute the break-down to the "normal chemical constituents" in the lake water. Ammonium nitrogen in sea water results in a more pronounced dissipation of chlorine and over a wider ammonia nitrogen to chlorine ratio. It is a matter of conjecture whether small amounts of ammonia in conjunc-

tion with sea water chemical constituents cause the break-down of hypochlorites or whether the sea water constituents cause a more rapid break-down of certain chloramines.

Considerable investigation¹⁻⁵ of surface water ammonia-chlorine treatment definitely indicates the formation of chloramines having a lower disinfecting power than chlorine alone. A perusal of Figure III fails to substantiate conclusively the supposition that chlorine-ammonia compounds are formed in sea water at a pH of 7.9. The curve correlates the degree of disinfection against the average residual chlorine during the disinfection period irrespective of the amount of ammonia present. A similar observation on a number of experiments in which the average residual chlorine during the disinfection period was the same for varying ammonia treatments would be more conclusive but experimentally quite impossible. It was observed, however, that the diminution of residual chlorine during the 15 min. period after the addition of sewage inoculation was 40 to 50 per cent less for ammoniated samples than chlorination alone. This possibly indicates the formation of chlorinous compounds having a lower oxidation potential which is not shown in the disinfecting power.

SUMMARY

Sea water has considerable disinfecting properties on fresh sewage organisms. An average of 80 per cent of the organisms are killed in 30 min.

In sea water polluted with from 2,000 to 20,000 organisms per ml., chlorination or ammonia-chlorination results in an average kill of 99, 99.9, and 99.99 per cent of the organisms in 15 min. time for mean residuals during the disinfection period of 0.15, 0.27, and 0.37 p.p.m., respectively.

Preammoniation of sea water (on the nitrogen basis) equal to $\frac{1}{4}$ to $\frac{1}{2}$ a

chlorine dose of 1.2 to 1.6 p.p.m. results in the dissipation of $\frac{2}{3}$ the chlorine in 10 min. An equal dissipation of chlorine occurs in 30 and 60 min. for an ammonia-chlorine ratio of 2.0 and straight chlorination respectively.

The rate of chlorine dissipation in chlorinated and ammonia-chlorinated sea water is relatively slow after the residual chlorine has reached the 0.5 p.p.m. level.

On the basis of the data obtained, disinfection is a function of the mean residual chlorine maintained during disinfection period irrespective of ammoniation. It appears that with low chlorine doses higher mean residuals may be maintained in *polluted* sea water with the aid of ammonium compounds.

Measles in Detroit, 1935*†

I. Factors Influencing the Secondary Attack Rate Among Susceptibles at Risk

FRANKLIN H. TOP, M.D.

*Medical Epidemiologist, Detroit Department of Health and
Herman Kiefer Hospital, Detroit, Mich.*

IN spite of the ubiquity of measles, epidemiological knowledge of the disease is based upon surprisingly few published studies. Among these Panum's monumental work in the Faroe Islands,¹ has by all odds contributed most. Conditions were unparalleled for determining the incubation period, the variation in the duration of prodromes and other factors which he investigated; yet the observations were made under unusual conditions in a community where measles had been absent for 65 years and where the population was highly susceptible to the infection. Chapin's contribution² is a study of measles occurring over 66 years (1858-1923 inclusive) in Providence, R. I. English workers such as Hamer,³ Brownlee,⁴ Soper,⁵ and Stocks,⁶ have contributed a considerable literature to the theory of the epidemic cycle; Stocks and Karn⁷ studied certain phenomena noted in a series of epidemics in St. Pancras. In this country, Collins⁸ and Hedrich⁹ furnish data concerning completeness of reporting and the age distribution of cases, while Emerson¹⁰ has evaluated the effect of current administrative

practice on the incidence, fatality, and death rates of measles. The recent publications on measles from the London County Council¹¹ deal with administrative and prophylactic measures applied within its jurisdiction.

In general, much which we profess to know about measles is dependent upon clinical impression and inadequate field investigations, without benefit of statistical treatment. Measles is more communicable than most infections. The opinion is quite general that most measles contacts will develop the disease. In fact, parents often consider it unfortunate when all susceptible children in the family do not take the disease at one time, reasoning that it is more convenient to be done with it at once.

It has been stated that 90 to 95 per cent of all children have contracted measles by the time they reach the age of 15 years.^{8,9,12,13} Granting this, is it not possible that the communicability of measles may be influenced by certain conditions which have been demonstrated to influence less communicable diseases? Chapin² found that 76.2 per cent of susceptible contacts at all ages developed measles when exposed. Stocks⁶ states (he contends that in St. Pancras, reporting was only 10 to 15 per cent under the actual occurrence

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

† This study was made possible through assistance of WPA Project Number 52-4-120-A Survey of Health Conditions in Detroit.

of the disease) that for every reported case of measles there are 3 susceptible persons exposed who do not contract it. He considers them to be temporarily immune, but again susceptible by the time the next epidemic occurs 2 years later. In the light of these contentions it would seem that there is ample justification for a further study of measles as it occurs in epidemic cycles in an urban community large enough to give an adequate number of cases.

SOURCE OF MATERIAL

During 1935, 27,430 cases of measles were reported in Detroit. The cases were classified by families: (1) families in which one or more susceptible contacts received some prophylactic agent, (2) families, no member of which received a prophylactic agent. This report is based on the second class. There were too many families in this class to make follow-up visits feasible. It was therefore determined to study thoroughly a small group—approximately one-fifth of all the families. A random selection was made by taking every fifth family record from the files. From the group thus selected the following were excluded for obvious reasons:

1. Families with no susceptible contacts
2. Families with an incomplete case record
3. Families in which a change of diagnosis was made
4. Children from orphanages and boarding homes
5. Families which could not be located on subsequent follow-up visits

Beginning August, 1936, follow-up visits were made to those families of the sample group in which one or more susceptible contacts had not been reported as having developed measles, to determine the accuracy of history of previous measles and the number of cases which had not been reported.*

After eliminating all families which could not be located on this visit, there remained a group of families no member of which had received prophylaxis, who serve as a sample of the larger untreated group.

Families in this sample group which were thoroughly investigated were shown not to differ materially from the larger group when compared with respect to: (1) age of the primary case ($p = .35$), (2) age distribution of susceptible contacts ($p = .13$) and (3) the proportion of susceptible contacts in each age group reported as developing measles ($p = .72$).

FACTORS CONSIDERED IN THIS STUDY

There are many factors which might affect the secondary attack rate among exposed susceptibles. Many are related to the nature of the infectious agent, in this instance probably a filtrable virus, and are outside the scope of this investigation. Certain aspects relating to the host and his environment are considered in the following questions which might have a bearing on the secondary attack rate:

A. Does the age or sex of the primary case affect the number of secondary cases developing among susceptible contacts?

B. What influence do age and sex of the susceptible contact exert on the secondary attack rate?

C. What is the relationship of the period in the seasonal cycle to the secondary attack rate?

D. What is the relationship of the number of primary cases per family to the secondary attack rate?

E. What variation of secondary attack rates is occasioned by exposure of susceptible contacts to repeated exposure to a constant intensity and differing intensities of exposure at one time?

DEFINITIONS

Before attempting an answer to the questions proposed certain terms are defined according to their use in this study.

* A visit was deemed unnecessary to families in which all susceptible contacts were reported as having contracted measles.

TABLE I

Attack Rates Among Susceptible Contacts According to Age and Sex of Primary Case

Age of Primary Case	Sex of Primary Case	Number Contacts	Number Secondary Cases	Attack Rate
Under 1	M.	5	2	(40.0)
	F.	7	4	(57.1)
1-4	M.	104	77	74.0
	F.	140	101	72.1
5-9	M.	633	551	87.0
	F.	679	602	88.7
10-14	M.	18	14	77.8
	F.	30	20	66.7
15+	M.	12	7	58.3
	F.	5	2	(40.0)
All ages	M.	772	651	84.3
	F.	861	729	84.7
M. & F.		1,633	1,380	84.6

Primary Case—The first case in a family presumably resulting from extra-familial exposure over 30 days after any previous case. Subsequent cases, the rash of which occurred within 6 days of the rash of the first case, were also called primary cases. Rash dates were used in determining the 6 day interval.

*One-primary Family**—A family in which one primary case occurred.

Multiple-primary Family—A family in which 2 or more primary cases occurred.

Susceptible Contact—Any child under 10 years of age reported as not having had measles previously who was exposed to a case of measles within the family. Susceptible contacts were limited to ages under 10 because children above the 6th grade were allowed to go to school and were not recorded as contacts.

Secondary Case—A case of measles developing more than 6 days after the onset of the 1st case in the family. The study included both reported secondary cases and those determined by subsequent investigation.

Exposure Period—An arbitrary period during which effective contact could have taken place. The number of days a measles case was infectious was arbitrarily placed at 8 days. This was arrived at as follows: 1 day before the prodromes plus 4 days of prodromes plus 3 days of rash.

Person-days of Exposure—The total number of days a contact was exposed. This was reckoned as follows: One person exposed to 1 case was considered as 8 person-days of exposure; 1 person exposed to 2 cases was considered as 16 person-days of exposure, whether exposure was simultaneous or in sequence.

Month—The month refers to the date of onset.

ANALYSIS AND DISCUSSION OF FACTORS

Age and Sex of Primary Case—Among 1,253 one-primary families, 1,380 secondary cases occurred with 651 attributable to male primary cases and 729 to female primary cases (Table I). The attack rate for contacts exposed to males is 84.3 and to females, 84.7.

The effect of age of the primary case on the secondary attack rate is shown in Table II. There are too few contacts under 1 and over 14 years of age to warrant consideration. Primary cases 5 to 9 years of age had the greatest number of contacts exposed of all primary age groups considered, with a total of 1,312 or 80.3 per cent of all contacts; furthermore, the contacts exposed to this age group had the highest attack rate in each contact age group.

* Unless otherwise noted, data relate to susceptible contacts in one-primary families.

TABLE II

Attack Rates Among Susceptible Contacts According to Age of Primary Case and Age of Contact

Age of Primary Case	Age of Contact											
	Under 1			1-4			5-9			10-14		
	No. Contacts	No. Cases	Attack Rates	No. Contacts	No. Cases	Attack Rates	No. Contacts	No. Cases	Attack Rates	No. Contacts	No. Cases	Attack Rates
Under 1	0	0	(—)	9	3	(33.3)	3	3	(100.0)	12	6	50.0
1-4	51	20	39.2	119	105	88.2	74	53	71.6	244	178	73.0
5-9	110	56	50.9	826	778	94.2	376	319	84.8	1,312	1,153	87.9
10-14	2	1	(50.0)	18	13	72.2	28	20	71.4	48	34	70.8
15+	2	1	(50.0)	11	6	54.5	4	2	(50.0)	17	9	52.9
All ages	165	78	47.3	983	905	92.1	485	397	81.9	1,633	1,380	84.6

The primary age group, 1 to 4, in comparison, had but 244 contacts, 14.9 per cent of the total. The attack rates for the respective primary age groups vary somewhat when considered for each age group of contacts but the differences do not appear to be highly significant ($p = .1$).

Age and Sex of the Contact—Of 1,633 susceptible contacts in one-primary families 786 were males and 847 were females (Table III). The respective attack rates were 84.4 and 84.7. Differences in attack rates between sexes are slight for each age group of contacts.

Of all contact age groups that of 1 to 4 contains 983 individuals or 60.2 per cent of the total (Table II). For each age band of primary cases, the

contact age group, 1 to 4, shows a greater number of susceptibles exposed, except for the primary case group, 10 to 14, with a higher attack rate in each instance. When all three of the contact age groups are compared, the attack rates vary considerably and are significantly different ($p = .0000$). When the contact age groups, 1 to 4, and 5 to 9, are compared, the difference is not very significant for a sample of this size. The attack rate in children under 1 year, however, is significantly lower than the attack rates in the older children.

Apparently, neither the sex of the primary case nor that of the susceptible contact influences the secondary attack rate. The age of the primary case has not been shown to influence very sig-

TABLE III

Attack Rates Among Susceptible Contacts by Age and Sex of Contact

nificantly the secondary attack rate, though the 5 to 9 primary age group gave the highest secondary attack rates. A significantly lower attack rate was found among susceptible contacts under 1 year of age.

Relationship of the Period in the Seasonal Cycle to the Secondary Attack Rate—The number of susceptible contacts by month appears in Table IV.

TABLE IV

Attack Rates Among Susceptible Contacts by Age and Month

Month	Number Contacts	Number Cases	Attack Rates
January	38	33	86.8
February	136	120	88.2
March	589	511	86.8
April	620	532	85.8
May	196	156	79.6
June	45	26	57.8
July	6	...	(0.0)
August	(...)
September	3	2	(66.7)
Totals	1,633	1,380	84.6

Early in the epidemic cycle, namely, during January and February, there were fewer contacts than noted for the immediate succeeding months, but the attack rate was as high in these as during March, April, and May. The attack rate for the individual months varies but slightly although toward the

end of the epidemic cycle, in May and June, there is a relative but not highly significant decrease ($p = .15$). Such differences as exist might be explained by infection of the more highly susceptible children earlier in the epidemic year.

Relationship of the Number of Primary Cases per Family to the Secondary Attack Rate—It is conceivable that more than one primary case in a family might increase the attack rate among susceptible contacts in the family. In Table V, data are presented showing the attack rates among susceptible contacts exposed in families with 1, 2, and 3 primary cases. In one family with 5 primary cases there was 1 susceptible contact, but measles did not develop. The number of contacts exposed in three-primary families is too small to consider but they are included to give the complete picture. When the data for one- and two-primary families are examined, it will be noted that with one exception, the age group, 1 to 4, the attack rates are higher in one-primary families than in the two-primary families. The variation is so slight, however, that it is not of much consequence. The number of contacts in the

two-primary families is small and larger totals might alter the result. However, it is remarkable that the attack rates for two-primary families is not notably higher than for one-primary families. It might appear unusual that exposure of susceptibles to 2 primaries should result in attack rates of the same or lower magnitude than encountered for similar age groups among one-primary families—on second thought, however, a plausible explanation appears. The attack rates for individual ages from 1 to 9 years, inclusive, vary between 60 and 93 per cent. If an attack rate of 85 per cent is taken as the mean for all ages considered, the hazard of exposure to additional primaries could possibly affect only 15 per cent of susceptible contacts. Thus, secondary attack rates in multiple primary families could not be much larger than for one-primary families. Again, it is possible that the remainder in multiple-primary families might be more resistant on account of selection—some of the subsequent primary cases being, in fact, secondary cases.

The Effect on Secondary Attack Rates Occasioned by Repeated Exposure to a Constant Intensity—A measles case was considered to be infectious for 8 days—arrived at as noted in the definition of "exposure period" given above. In Table VI, susceptible contacts are classified by age, exposure

periods, and person-days of exposure. The majority of contacts had one exposure. Very few contacts remain who were exposed for two periods, and but one contact was exposed for three periods. In the one-exposure group, the secondary attack rate for all contacts exposed is 88.1. For contacts exposed twice, a period of 16 days, the attack rate was 37.5. Evidently the few contacts who escape measles after one exposure have a decidedly smaller probability of contracting measles when exposed a second time but the additional hazard is still real. Whether part of the decreased risk at second exposure is due to sub-clinical infection with development of temporary immunity resulting from first exposure, is conjectural. It is possible, in the light of Panum's observations, that a considerable number of contacts who do not contract the disease on second exposure may have given an incorrect reply when questioned regarding an attack of measles in the past. Again, the highly susceptible may have been eliminated by the one-period exposure which would tend to make the attack rate lower in the two-period group.

The Effect on Secondary Attack Rates Occasioned by One Exposure to Various Intensities—The effect on the secondary attack rate of exposure to multiple primary cases is considered above and leads to further investigation

of the possible effect of intensity of exposure (Table VII). An exposure period of less than 8 days is possible if the primary case was removed to hospital during the 8 day period. Therefore, in families in which there was 1 primary case, susceptible contacts may have been exposed for less than 8 days, for 8 days, or if exposed to additional members of the family as they developed measles, for more than 8 days. Each additional exposure to another measles case in the family was considered as an additional 8 days of exposure. Thus, a child in a one-primary family may have been exposed for 16 days—8 days to the primary case and 8 days to another member of the family. The great majority of contacts were exposed for 8 days. The few remaining contacts are principally in the 16 person-days of exposure group. Table VI is almost a duplicate of that part of Table VII which deals with contacts to one-primary cases; the differences are the result in Table VI of exclusion of contacts exposed to more than 1 additional familial case in 1 exposure period.

When two-primary families are considered, the majority of contacts were

exposed for 16 days, that is, exposed to 2 primary cases but to no subsequent secondary cases. No comment is warranted for contacts to families with 3 primaries, for their number is too small.

To determine adequately the effect of intensity of exposure in the same period of time, the attack rates resulting from exposure for an 8 day period in one-primary families, a 16 day period in two-primary families, and a 24 day period in three-primary families should be compared (Table VIII). In other words, a comparison is being made between contacts in one-primary, two-primary, and three-primary families who were not subsequently exposed to a secondary case. The attack rate for contacts exposed in a family with 1 primary case is 88.1, for those exposed to 2 primary cases 80.0, and for 14 contacts exposed to 3 primary cases, 78.6. There is little difference between the secondary attack rates. A variation in intensity of exposure as measured by the number of cases in the family to which a susceptible is exposed during the same period of exposure (8 days), therefore, appears to exert no significant effect upon the secondary attack rate.

Syphilis Meeting

ASSEMBLY of Laboratory Directors and Serologists, Hot Springs National Park, Arkansas, October 21-22, 1938—A meeting under the auspices of the Committee on Evaluation of Serodiagnostic Tests for Syphilis, of the U. S. Public Health Service, with Surgeon General Thomas Parran, Chairman, is scheduled for October 21 and 22, 1938, at Hot Springs National Park, Ark.

The aims and purposes of the assembly will be to consider means and methods to improve and to make more generally available the serologic tests, which are so important in syphilis control work. Tentative arrangements call for the presentation of the program in four sections.

The first section will consider the need for adherence to conventional technic in the routine performance of reliable serodiagnostic tests. Need for training of laboratory personnel will be the subject of the second section.

The third section will discuss the prosecution of the studies to evaluate the performance of serologic tests within the states. The fourth section will consider the desirability of licensing or approving, for the performance of serodiagnostic tests for syphilis, laboratories within the states by the respective state departments of health.

A separate committee will draft recommendations for each of the four sections for presentation to the assembly. The respective chairmen of these 4 section meetings will be Drs. Walter M. Simpson, Dayton, Ohio, Arthur H. Sanford, Rochester, Minn., F. E. Senear, Chicago, Ill., and H. H. Hazen, Washington, D. C.

Out of the meeting should come a crystallization of opinion with regard to the important problems which will be considered. Those interested in obtaining further information should write to the Surgeon General, U. S. Public Health Service, Washington, D. C.

Nutritional Education in the Home

Dutchess County (N. Y.) Project*

BERTRAND E. ROBERTS, M.D.

District State Health Officer, Poughkeepsie, N. Y.

AN immense mass of evidence of the necessity for effective education of the public in the field of nutrition has accumulated in recent years. This was presented by the President of this Association at its last Annual Meeting as one of several outstanding health needs of the nation.

Decision as to the best methods of administrative approach to the problem offers many difficulties. Research has indicated that the formerly highly vaunted method of attempting to discover by physical examination those who are in need of nutritional education is of limited value, as there is no practicable procedure available for detecting in this manner much more than cases of gross malnutrition. Such cases are comparatively uncommon in most parts of this country.

On the other hand, the optimum diet recommended by authorities in the field of nutrition is far from being realized among a considerable part of the population. It is no doubt true that such a diet has been approximated among the better informed. The increased physical development noted among students entering college, as compared with that of the previous generation, is

probably a reflection of the great spread of knowledge in this field during the present century.

One principle of economics which has somehow stuck in my mind since college days is "the law of diminishing returns." This law seems already to have begun to operate in certain branches of the public health field. For instance, diphtheria has been practically eliminated in areas where effective measures have been taken to immunize the younger children, but a much greater effort proportionately is required to bring the percentage of immunizations to the vicinity of 100, while the returns, namely the reduction of diphtheria morbidity, are practically nil above, say, the 50 per cent point.

Similarly the question may well be raised as to whether the same law is not operating already in the field of nutritional education. Are health authorities justified in further large expenditures for group demonstrations and newspaper publicity for this purpose? Have not the large bulk of those who intelligently read the papers, attend group meetings, and the like, already been well instructed as to a proper diet? Is it not to be expected that the further expansion of activities along these lines will very soon reach a point where comparatively small returns, in the form of better nutrition, will result?

* Read at a Joint Session of the Child Hygiene, Food and Nutrition, and Public Health Nursing Sections of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

Whatever may be the answer to these provocative questions, few, I think, will disagree with the proposition that the greatest lack in nutrition is found among the underprivileged groups of the population, and, further, that these groups respond poorly to educational measures along the lines mentioned. In order to reach this group effectively, individual instruction of the mother in the home must be brought about. The public health nurse is logically the agent who should be depended upon for this work. She is the one who has already attained a standing among such mothers in matters relating to health. She knows appropriate methods of approach to secure action. She is already today's real health educator in the homes of the very people who most need better nutrition.

For the nurse to do effective work in this field, she must not only be instructed in the principles of nutrition, but she also needs a plan of operation under which she can gauge the lacks in the dietaries of the families with whom she works and take measures toward their correction.

This does not mean that she must be a full-fledged nutritionist. Really, all she needs to know about diet is what every intelligent mother can be expected to learn, with some additional information as to methods of dealing with the food customs of the various nationalities represented in the nurse's district. It is therefore desirable that the nurse be instructed in the basic principles of nutrition by one who is competent in this field, and that she may obtain advice from time to time on special problems that may arise in the course of her work.

A project in nutritional education has been in operation under the writer's direction in Dutchess County, N. Y., beginning in December, 1933, when the services of about 40 work relief nurses were obtained from the Civil Works

Administration. The project was further extended, though only in February and March, 1934, by the employment, through the CWA, of a nutritionist, Mary K. Swint, and 29 women workers whom she instructed and supervised. Only one of this group was a nurse.

The nurses in the other group engaged in this project have varied in number, and have been employed under various governmental auspices (TERA, CWA, WPA) as a part of a state-wide nursing project, under which bedside nursing was provided to patients on relief or in poor circumstances, and assistance was given in other public health nursing activities. The Dutchess County nutrition project was carried on by the nurses when their full time was not required for these activities.

Valuable voluntary assistance was rendered in the instruction of the nurses by Grace Thompson, chief dietician of Vassar Brothers Hospital, and by Ruth Wheeler, Ph.D., Professor of Physiology, Vassar College. The textbook *Food in Health and Disease*, by Catherine Mitchell Thoma was used by Miss Swint as a basis for an intensive course of instruction, lasting about a week. The workers were also taught economical ways of purchasing food, and were given some idea of proper methods of psychological approach in home visiting.

Each worker was supplied with literature on nutrition which was given out in families where it was felt that it would be profitably used. The workers were also instructed to provide the housewife with sufficient explanation in connection with each piece of literature.

In addition to general instructions as to nutritional requirements the housewives were given individual demonstrations in food preparation where it was felt necessary. For instance, they were shown how to use salmon in the form of a loaf or salad. Frequently a problem was found as to the proper use of

milk, especially in those families receiving public relief, where a supply of evaporated milk was often furnished but the housewives had insufficient knowledge in its proper use. Another form of demonstration was that of desirable methods of vegetable preparation, which are very commonly not understood. Sometimes it was, of course, necessary to make return visits in order to see that the instructions were effective.

The workers were able to be of some assistance to families on relief who complained of difficulties with their grocery orders. The worker would discuss the orders with the housewife and, if the latter so desired, would accompany her to the grocery and help her in choosing her supplies. In some instances the worker made out sample menus for the week with housewives, especially if they complained that insufficient food was received from the welfare agency. By this method it was often possible to demonstrate that with a little planning the weekly grocery order would provide sufficient food for the family.

Investigation forms, prepared with the assistance of Professor Wheeler, were used by all the workers, who were furnished with detailed stencilled instructions as to the method of filling them out. Each form provides spaces for recording the estimated weekly use of various kinds of foods during a year previous to the first visit and during a year subsequently, together with data regarding the composition of the household, family income, etc.

These forms for summarizing the use of foods are believed to have been of distinct advantage. Without some such form it is hardly possible to get an adequate idea of the nutritional habits of the family. They also probably aid to some extent in impressing upon the mothers' minds the importance of the work. After the form has been filled

out it serves as a talking point on which to base suggestions for dietary changes. On the other hand, I hold no brief for the specific form used. A considerable part of it was prepared for special purposes which would not apply to usual routine work. Forms of the future will no doubt be much simpler.

The data as yet have been analyzed only from the standpoint of increases or decreases in the use of milk, cod liver oil, foods rich in iron, and fruits or vegetables (exclusive of potatoes), as related to place of residence, increase or decrease in income, number of children and relief status. A quantitative estimate of the sufficiency of the dietary has not been made, both because time and personnel were insufficient, and because it is doubtful that the recollection of the housewife was accurate enough for this method to be of great significance, except possibly for such items as milk and cod liver oil. (See Note.)

NOTE: For those who are interested in the technical aspects of the subject, it is desirable to record the methods of procedure by which changes in the nutritional status of households were determined for the purposes of this study.

Various previous studies have indicated that the principal factors in which the American dietary is deficient are calcium, vitamins C and D, the latter vitamin especially among young children, and iron. (Pellagra is practically non-existent in New York State, as in most sections of the country, hence consideration of dietary improvement to combat this disease was not necessary in this project.)

The chief objective in the project therefore was improvement of the dietaries in these respects. Likewise the analysis of the record forms was made on the same basis, an estimate being made of increases or decreases in foods rich in these factors; this estimate was made in each instance under four categories: M (milk and cheese—for calcium); C (cod liver oil—for vitamin D); F (foods rich in iron); V (fruits and vegetables, exclusive of potatoes, for vitamin C).

As some items of food in each of the fore-

Nearly all the families covered in this project were on relief during some or all of the 2 year period, or received very small incomes. For 423 families the data were sufficiently complete for analysis—272 in the city of Poughkeepsie, 34 in the city of Beacon, and 117 in the rest of the county, the latter being largely in the villages and hamlets, as the workers were unable to cover remote rural sections because of lack of facilities for transportation. The analysis indicated that the dietary was improved during the year following instruction in 68 per cent of the households; it was found to be approximately

the same in 15 per cent, and impaired in 17 per cent, the impairment, as might be expected, being most marked among families with decreased incomes. It is of interest, however, that even among the 93 families whose incomes declined in the second year, the analysis indicated that the selection of foods improved in 53 per cent. Among those in which the income was increased (205 families), and in which it was approximately the same (125 families), the comparable figures were 71 per cent and 75 per cent, respectively. The cost of living was somewhat higher the second year, so that families with

NOTE (continued)

going categories except C might show an increase while others showed a decrease, a system of approximate equivalents was devised for estimating the relative values of the changes, based, in each category, on the approximate content of the food items in the special food factor for which the category was established. The following equivalents were used:

Category M

1 qt. fresh milk; 1 large can evaporated milk, $\frac{1}{4}$ lb. cheese (except cream cheese).

Category F

1 lb. beef; $\frac{1}{4}$ lb. liver; $\frac{1}{3}$ lb. dried beans; 1 can baked beans; 1 lb. mutton; 1 lb. pork (except bacon and salt pork); 3 lb. bacon; 1 lb. spinach (greens); 1 lb. dried prunes; 1 lb. ham.

Category V

1 lb. or $\frac{1}{3}$ head cabbage; 1 lb. or 2 heads lettuce; 1 lb. greens; 1 lb. (or can) tomatoes; 1 lb. or 3 oranges; 2 lb. or 6 apples; 2 lb. (or bunches) carrots; 2 lb. (or bunches) beets; 1 can tomato juice; 2 cans pineapple juice; $1\frac{1}{2}$ cans grapefruit juice; $1\frac{1}{2}$ lb. grapefruit; 2 lb. (or cans) other fruits and vegetables (except potatoes).

A clerical worker was instructed in the use of these equivalents until it was found that she was proficient in determining as to whether there was an increase or decrease in each of the categories under consideration and in marking the forms accordingly, e.g.: " $M \div F \div C \div V \div$." Changes of less than 10 per cent were considered as indicating no increase or decrease, in view of the fact that

the estimates were subject to a margin of error, even though averaging several food items tended to narrow the margin. It is recognized that the approximations are especially wide in reference to fruit and vegetables, as adequate quantitative tables on the vitamin C content of foods are not yet considered to be available. On the other hand, all forms not found by the clerical assistant to show increases or decreases in all four categories, were appraised by the writer. It is of interest that this appraisal seldom indicated a need of altering the clerical assistant's estimate as to the change in the nutritional status of the household. In general, under the system of estimates outlined above, the nutrition status was considered to be improved or impaired, if increase or decrease, respectively, was indicated in three or four of the categories, or in one or two of the categories when no increase or decrease was indicated in the remaining ones. Occasionally the change in nutrition status was otherwise classified, for example, the status was held to be improved in households where there was a large increase in milk consumption together with small estimated decreases in the use of fruits and vegetables and of foods rich in iron.

It is believed that a similar system could be inaugurated by many health agencies without the necessity of any great increase in personnel. In educational field work of this character it is of course impossible to obtain anything like the exactness in estimating results which can be maintained in laboratory work.

The writer will be glad to furnish copies of the record forms and the instructions as to their use upon receipt of a written request.

income unchanged throughout the 2 years to all intents and purposes suffered a reduced income.

Higher percentages in improvement were found among households in which there were children, than among childless households—70 per cent in those with 1 to 3 children, and 65 per cent in those with 4 or more children, as compared with 60 per cent among the childless. As there were only 29 households without children, however, this observed difference, while of interest, is hardly of statistical significance.

The recorded improvement varied considerably according to locality, the cities faring better than the smaller places; the percentages with improvement being 73 per cent in Poughkeepsie, 65 per cent in Beacon, and 57 per cent in the rest of the county. These differences may be due, to some extent, to variation in the inherent characteristics of the respective populations, but probably also reflect the fact that the nurses in the cities could find more time to devote to the work than those in other places. Also, in the city of Poughkeepsie the nurses worked under somewhat closer supervision.

Some of the more cynical among my hearers may wonder why no investigation was made of a control group, namely, families in which such educational work had not been carried on. To such questioners it is well to confess that the possibility was considered, but it was not put into effect because, in the first place, the selection of a control group is subject to more than usual difficulties in work of this sort, and in the second place, it would probably be impossible to select a suitable group whose members would not also be influenced by the educational work done among the other group, though at second-hand, that is, as the result of social intercourse between the two groups.

Neither was it deemed feasible, nor even desirable, that an attempt should be made by physical examinations and clinical tests to discover whether a reported improvement in diet was accompanied by a corresponding improvement in physical condition. Such examinations and clinical tests are not yet simple and inexpensive enough, nor conclusive enough, to be recommended for large-scale work. Suffice it to say that what the human race needs is an adequate, well balanced diet, and that whatever is instrumental toward this end has its own justification. It is not necessary to strive for perfection, for the perfect diet is not yet known, nor is the perfect physical examination.

Nearly all of the nurses, as well as the lay women, employed in this work, had had no previous experience in the public health field. It is of course possible, and even likely, that fully trained and experienced public health nurses could have obtained a higher percentage of improvement. On the other hand, I can recall no instance in which trained public health nurses in any comparable area have been able within a single year to persuade nearly such a high proportion of mothers to adopt an even simpler procedure, namely the immunization of their preschool children against diphtheria. It must be remembered that dietary improvement involves changing the habits and tastes of a lifetime and altering customs handed down from generation to generation.

The method outlined does not involve the necessity of creating a large body of additional workers, as it can be readily integrated with the usual program of generalized public health nursing. All that is needed is a reasonable amount of basic knowledge in nutrition, which many of the nurses have already, and an additional record form for their family folders, which many will no doubt welcome!

Indiana's Dental Health Program*

HOWARD B. METTEL, M.D., AND MARY H. WESTFALL, D.D.S.

Chief; and Dental Health Educator; Bureau of Maternal and Child Health, Indiana State Board of Health

IN the organization of the Bureau of Maternal and Child Health program of the Indiana State Board of Health, dentistry has been given its rightful place. It must be understood that the program in no way can be considered as an entering wedge into state dentistry. The dental program in Indiana is a means of educating the people to the needs for dental attention, and caring for the dental needs of children whose parents are unable to provide the dental care necessary to the health of their children.

This dental health program has been made possible through funds made available to the Bureau of Maternal and Child Health by the Children's Bureau of the U. S. Department of Labor, which have been used in carrying out both the educational and demonstration services.

The Indiana State Dental Association is composed largely of dentists who see much farther than the mere mechanics of dentistry; who are aware of the great need for dental education, as well as for dental care for the children of Indiana; and who know that if we desire a better health record for the state, for children and adults as well, inspection and care must be given

to the oral cavities of children and adults.

The preliminary plans for Indiana's dental program were first formulated by the State Health Commissioner, the Director of the Bureau of Maternal and Child Health, and the Advisory Committee of the Indiana State Dental Association. Through this coöperation, and with the technical advice of the late Colonel C. T. Messner, Senior Dental Surgeon of the U. S. Public Health Service, a plan was outlined and submitted to the Trustees of the Indiana State Dental Association in May, 1936. This met with the enthusiastic and unanimous approval of the Trustees of the Dental Association.

The dental health program as inaugurated in Indiana consists of three branches: Organization, Demonstration, and Education.

ORGANIZATION

Believing that the most effective end-results of health work are gained when all health agencies coöperate and follow the same road, a concentrated effort has been put forth to secure the coöperation of the dental societies, county medical societies, and lay organizations interested in public health such as Parent-Teacher Association, the tuberculosis association, the American Red Cross, the American Legion, the service clubs, and other groups. Close coöperation with the Bureau of Public Health Nurs-

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

ing of the State Board of Health has been maintained. The part of the trained county public health nurse is important in any dental program. The nurse is of greatest assistance in making the initial contact in her work in the public schools, and can be depended upon to find those patients needing dental care, and to send the patients first to a private dentist or the dental unit.

In order to administer the plan, a technical staff was appointed, which consists of a dental health educator, a dental operator to work in the mobile unit, and a technical adviser.

DEMONSTRATION

The demonstration branch consists of a mobile dental unit—a complete dental office on wheels. Demonstration work according to the interpretation of the U. S. Children's Bureau, and the Indiana Plan, means actual work performed on patients. The mobile dental unit has all the physical adjuncts necessary to render efficient dental services. It contains a dental chair, and instrument cabinets with instruments of the latest design, an adequate laboratory, supply and linen cabinets, a sterilizer, and modern lighting equipment. This mobile unit was patterned after the one used in the Indian Reservations and the Coast Guard Service of the U. S. Public Health Service. A dental operator has been placed in charge of the work in the unit, and he does not use an assistant.

In order to select the initial demonstration area in which to locate the dental unit, the statistics of the various counties were studied to assist in determining not only the field which would be presented for demonstration, but also the financial conditions of the citizens. At this time a careful study was made of the reports of the Indiana Bureau of Vital Statistics, the Indiana State

Planning Board, and the report of the Dental Survey of School Children, U. S. Public Health Service *Publication No. 226*, from which it was found that in Greene and Owen Counties, during the years 1926 to 1933, inclusive, 6,458 children had been born. Considering the deaths and removals occurring during this time, it was approximated that there were 6,000 children in these two counties between the ages of 3 and 10 years. Therefore, in order to limit the program so as to make a proper demonstration, only those children between 3 and 10 years of age, of indigent parents, were eligible for service.

The next point was to study the financial income of those people, which would be such as to render them unable to pay for private dental service for their children. Here again the information was utilized in selecting Greene and Owen Counties as the first demonstration area. Such statistics as the agricultural income per square mile, manufactured products per capita, total assessed property per capita; percentage of population on relief rolls; and the number gainfully occupied persons receiving an income of less than \$1,000 per annum were used.

The next problem was to secure the coöperation and support of the local dentists of the proposed demonstration area. It was learned that the dentists of the selected area had an outstanding record in that every dentist practising in that area was a member of the local component society, the Indiana State Dental Association, and the American Dental Association. With this type of active organized dentists, the plan, as well as the approval of the plan by the Indiana State Dental Association in May, 1936, was placed before them for their approval. Complete support and coöperation have continued since the establishment of the demonstration service.

With the completion of the preliminary organization plans and the purchase of equipment, the unit was put into operation. According to the plan as adopted by the Advisory Committee of the Indiana State Dental Association, patients eligible to receive the benefits of dental care in the unit are those children between the ages of 3 and 10 years, whose parents are financially unable to provide for the dental care necessary. The services consist of amalgam and cement restorations, prophylaxis, and extractions.

The dental plan in Indiana establishes 3 sources from which assignment of patients to the unit can be made. A patient may be admitted to the unit for treatment upon the recommendation of the county public health nurse, since the unit will not be assigned to any county not having such a nurse, and, inasmuch as it is felt that no person is better acquainted with the people of the county and the manner in which they live than the county health nurse. Second, the local relief agency present in every county and township is permitted to refer any patients who are carried on their relief rolls. The local dentist, over his own signature, is permitted to send patients to this clinic. Thus, through these agencies, careful check is kept on patients in order that there may be no patients admitted who are not entitled to the free services.

Recommendation by the referring agencies does not mean that the patient can be taken into the clinic without further formality. Before any work can be performed on the child, the parent or guardian is requested to sign a written request for such service. It is understood that it is not a permit to work on the child, but a request from the patient that the work be done. After all of these preliminary procedures have been completed, the patient is accepted for actual dental work.

EDUCATIONAL WORK

This part of the program is under the supervision of Dr. Mary H. Westfall, the Dental Health Educator of the Bureau of Maternal and Child Health. One of the most far reaching educational devices used is the distribution of free literature to persons requesting it. The bureau to date has not prepared any literature, but, believing that the various pamphlets published by the American Dental Association adequately present the public health problems, has purchased pamphlets from them for distribution. Three publications are obtained from the Good Teeth Council for Children, Inc., Chicago.

The mobile dental unit is considered as part educational in its functions. Before the unit is sent into a community, the people are instructed in dental health matters by means of speakers before Parent-Teacher Associations, at service club meetings, etc. When the oral examinations are made in the schools in an effort to locate indigent children needing dental care, the children, of course, relay the information to their parents, and in the end the entire community becomes dental health minded. There is no point in attempting to teach any phase of public health education through the children only; this information must be presented to the parents if best results are to be obtained.

In coöperation with the Good Teeth Council for Children, Inc., we have conducted various visual educational projects in the schools in the form of puppet shows, magic shows, and nature study programs. During the past school year these programs reached 70,000 school children in the public and parochial schools and were most effective. Another form of dental education was the distribution weekly of mimic broadcast sheets to the school teachers. These stories are in the form of travel-

ogues; are printed copies of actual radio broadcasts by George Wood Clapp, D.D.S., of New York, over some eastern stations; and they can easily be integrated with projects in health, physical education, English, composition, reading, spelling, history, art, etc. The material is particularly suitable for grades 5 to 9, inclusive. There is no expense to the schools for this material, being furnished through the courtesy of the Bureau of Maternal and Child Health, the Indiana State Dental Association, and Dr. Clapp. These broadcasts are approved by the American Dental Association—the highest authority in the dental profession. This year a state-wide dental poster contest is being conducted in the public schools of Indiana, sponsored by the Indiana State Board of Health and the Indiana State Dental Association.

Being convinced that the rôle of the county public health nurse is of utmost importance in any type of health program for the public, Indiana last year conducted the first of a series of concentrated dental nursing courses. The courses were conducted at Indiana University School of Dentistry. In all, 60 nurses attended the two courses offered, and many favorable comments were made by them to the effect that they were greatly helped in making general oral health examinations of the school children. The importance of diet and nutrition was also stressed in these courses. During the coming year we plan to repeat these courses, having perhaps three courses during the school year.

In order that teachers in the public schools may be more competent in disseminating the proper dental health information to the children, during the months of July and August the Bureau of Maternal and Child Health, coöperating with the Speakers' Bureau of the Indiana State Dental Association, and the State Department of Public

Instruction, conducted a series of dental health lectures in 4 different teachers' training colleges in the state. These courses likewise met with the enthusiastic approval of the school authorities, with requests being made that similar courses be offered next year.

SUMMARY

The organization and administration and educational programs of the Indiana dental program as carried out by the Indiana State Board of Health has been presented. It is planned to proceed with this program slowly, and to improve it with each year's experience. To date the mobile dental unit has located in only the original demonstration area, namely, Owen and Greene Counties. The people in this section are in dire financial circumstances and there is much work to be done there. In most cases the toothbrushes provided the children coming to the dental unit, are the first ones which they have ever had.

The Indiana State Board of Health believes in education and more education; in teaching the parents that poor health is a handicap in any life's work; and that prevention is easier and often shorter—and certainly much cheaper—than cure. Another aim is to teach the children that teeth are vital parts of the body and should be so considered and cared for.

In considering this program, one has visions of placing more dental units in the state in caring for those children whom we have and always will have—those who cannot care for themselves. It has been interesting to note the satisfactory coöperation from the dentists, the schools, and the public at large throughout the state. The dentists inform us that, without doubt, in those communities in which the dental unit has been located the general public has become more "dental health minded," that more children who can pay for

dental care are going to their private dentists for this care.

It is the aim of the State Board of Health to develop this demonstration so that in the future perhaps one county or several counties grouping together can appropriate local funds for furnishing original equipment which may carry forth a program of their own, patterned after the one which has been demonstrated by the State Health Department. This is in the future, and per-

haps it is a long way off. It is certain that Indiana's dental program will be carried along in close coöperation with the American Dental Association, the Indiana State Dental Association and its component societies. The Indiana State Board of Health feels that these are the men who know best the needs and defects of their own communities, and should be the persons to advise us in carrying forth the future dental health program.

Plumbing in Low Cost Housing^{*}

JOEL I. CONNOLLY, F.A.P.H.A.

*Chief, Bureau of Public Health Engineering, Board of Health,
Chicago, Ill.*

IN view of the fact that drinking water which has been contaminated through faulty plumbing may spread disease, it is a public responsibility to assure that plumbing in all buildings is safe. It is just as important in low-cost housing as in any other, especially in view of the economic status of the occupants, and their sometimes inadequate nutrition, and lower resistance to disease.

Even in dwellings of the lowest cost, it is necessary to have adequate facilities for safe drinking water, cleanliness, and for removal of human excreta. It is believed that there is general agreement on a minimum for each family unit, of a kitchen sink and a bathroom containing one water-closet, one bathtub, and one lavatory. The bathroom should be accessible without going through a bedroom.

The fixtures should meet a few simple requirements. They should be provided with a safe supply of water. They should be proof against siphonage of fixture contents into the water supply system. They should be connected to a sewer leading to some adequate means of sewage disposal. They should be impervious and easily cleaned. Except the toilet bowl, all the fixtures should be supplied with hot and cold water through a mixing faucet for controlling the temperature. They should be prop-

erly trapped and vented. Pipes should not be larger or more costly than necessary, either in first cost or maintenance. The water should be from a safe, preferably public, supply. No auxiliary water supply should come into the building.

How is siphonage of fixture contents to be avoided? By removing the chief cause, which is the presence of submerged inlets to fixtures.

For example, a bathtub may be filled to a level where the inlet is submerged beneath the water surface. Then, if a sufficient decrease in pressure occurs in the water supply pipes, as may easily happen from a number of causes, the tub may function like an elevated storage tank and supply water to fixtures at lower elevations.

The ordinary flush tank for a water-closet is a fixture where the inlet is nearly always submerged, because the hush tube on the ball cock usually extends almost to the bottom of the tank.

A water-closet equipped with a flush valve is another example of a submerged inlet fixture.

If the inlet to every fixture is brought well above the rim, siphonage will not occur. Suggested minimum distances for the inlet above the rim are 1" for lavatories, 1½" for sinks, and 2" for tubs.¹

Where a fixture is covered, such as a flush tank, it is customary to place the inlet below the rim. Progressive plumb-

^{*} Read at a Special Session of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

ing manufacturers make open fixtures almost entirely with over-rim supplies. They should now give careful study to the development of a satisfactory flush tank from which siphonage cannot take place.

Suggestions for improvement are (a) to eliminate the submerged hush tube and devise some other method of quieting the entrance of the water, (b) to place the water pipe, fittings and valve entirely above the highest possible level of the water surface in the tank, (c) to increase the effectiveness of the overflow pipe, (d) to provide means for maintaining atmospheric pressure above the water surface, without drawing air through the water-closet, in case a vacuum in the water pipe withdraws the air, and (e) to elevate the bottom of all tanks above the rim of the toilet. In some instances, certain of these improvements have already been made.

A tank constructed along these lines is to be preferred over one which has no protection against siphonage or one which depends upon some mechanical device of questionable reliability to prevent the return of water from tank to pipe. On new construction, nothing less than a definite air gap between water inlet and fixture rim should be approved by those who are charged with the responsibility of construction, whether for low cost housing or any other type of building.

In the correction of existing submerged inlets, one is often confronted by the additional expense of rebuilding or redecorating defaced walls, to secure an air gap. This usually greatly increases the difficulty of securing the changes. To avoid such extra expenses, various methods have been devised. For example, a "goose-neck" pipe may be attached to the submerged inlet of a built-in tub, thus raising it above rim. As long as no leaks develop in the portion of the pipe below the rim, this is satisfactory.

Mechanical vacuum breakers are widely advertised for protection of flush valves on toilets. Obviously, a mechanical device which is subject to deterioration, liming up, sticking of moving parts, noise, maladjustment, corrosion, leakage, or variation in manufacture is vulnerable to criticism. On the other hand, in existing buildings it may be possible to secure a considerable degree of protection by permitting, without definitely approving, the installation by competent plumbers working under careful inspection, of a combination of a non-return stop and a suitable vacuum breaker, where undue delay or even complete failure to achieve improvements might result from rigid insistence upon an air gap. Such installations must be made under strict limitations. Not all vacuum breakers are suitable.

Failure of water pressure is more likely to occur on upper floors than on lower ones. Therefore, in correcting existing submerged inlets, the work might well start at the top of the building and progress downward, until the entire plumbing system has been safeguarded.

In low-cost houses, the use of soil stacks 3" in diameter will usually be possible and desirable. Stacks of this size permit economies in construction of walls and partitions, as well as in the plumbing.

A code prepared by the late Professor George C. Whipple and associates,² states that a 3" soil stack could take care of as many as 8 bathrooms of the type here considered, each containing one water-closet, one tub, and one lavatory. Thus, if 2 bathrooms adjoin on a floor, one stack of this size could serve a 4 story tier of bathrooms. Four kitchen sinks, one above the other, would require only a 1½" waste stack under this code. Thus, for low-cost buildings, 4 stories or less in height, 4" partitions would suffice even where they must contain soil and waste stacks.

In apartment buildings for low-wage earners, the tenants expect to use a common laundry. Such facilities are quite likely to be placed in the basement. Floor drains in such locations will be kept sealed well enough by the water which inevitably spills on the floor, without the use of special devices to maintain the seal.

The possibility of flooding basements with sewage during storms should not be overlooked. If sewers are likely to be overloaded, some automatic device should be installed to keep the basement dry. Overloading is likely to occur in slum clearance projects where the sewers are old and in poor repair, and where large, densely populated, low-cost developments replace small, old buildings.

If the flooding of sewers is not prolonged, it may be sufficient to use an automatic back-water valve on the house drain, with the rain water downspouts connected between this valve and the street sewer. These valves may be either hydraulically or electrically operated, and controlled by floats or electrodes.

If flooding of street sewers is prolonged, the discharge from fixtures in the building itself may cause sewage to back up into the basement while the back-water valve is closed. In such a case, it is best to build more adequate sewers. Failing in that, the next best thing is to have basement fixtures drain to a sump equipped with an automatic sewage pump or ejector. Hydraulic ejectors are dangerous for use because of the likelihood of direct cross-connections between the drinking water system and the sewer. Electrically driven pumps or ejectors operated by compressed air are to be preferred.

Special thought should be given to maintenance costs of house drains. While extra heavy cast iron pipe costs more at first, it is less likely to give trouble and involve future expenses.

If refrigeration is furnished from a central ice plant, the problem may arise as to the re-use of the condenser water. Water which has been used for any purpose in a building should not thereafter be used for drinking purposes. One should guard against the possibility that the condenser may drain directly to the sewer, constituting a dangerous cross-connection and inviting outbreaks of water-borne diseases.

Economies may be made, under certain favorable conditions, in venting soil and waste pipes by the use of circuit or loop vents. One should make sure, however, that the loop vent will perform its function.

The code² above mentioned states: "A branch soil or waste pipe to which two and not more than eight water-closets, pedestal urinals, trap standard slop sinks, or shower stalls are connected in the series may be vented by a circuit or loop vent, which shall be taken off in front of the last fixture connection." Whether any money can be saved by loop venting is largely dependent upon the individual arrangement of fixtures.

An item sometimes overlooked is the possibility of sewer pipes passing over uncovered water tanks or places where ice, beverages, or foods are stored, handled, or prepared. Although the pipes may be tight when first installed and inspected, they eventually corrode and leak, leading to contamination of water, ice, or food below.

Plumbing codes, generally speaking, need to be brought up to date, both to protect public health and to permit uses and materials which will give better and more lasting plumbing.

Housing and Health*

ROLLO H. BRITTEN, F.A.P.H.A.

Senior Statistician, Division of Public Health Methods, National Institute of Health, U. S. Public Health Service, Washington, D. C.

WHAT is the connection between housing and public health? What is the importance of better housing in the United States today? How does the housing problem fit into the general sociological and economic situation? For these things are the health officer's concern once he attempts to deal with this problem.

I like to think of housing as the home environment of the person, and health as a state of physical, mental, and social efficiency. The intimate relation of these things is obvious. And this committee, in framing hygienic standards for housing, is also thinking in these broad terms.

We know that the population living under adverse housing conditions is to an extent a selected population, is subject to much chronic ill health, and is handicapped by all the concomitants of low income. In a recent paper, DallaValle¹ discusses several of the factors which are related to sickness and death rates in slum areas, namely, decreased opportunities for self improvement, poor housing, malnutrition, lack of medical care, and exposure to unhealthful occupations. Hence, it must be recognized that the observed excess

in illness and mortality rates in slum areas cannot be blamed entirely, perhaps not even chiefly, on the housing²; nor can we today evaluate precisely the part that housing itself plays. However, it is not the only health problem of the low income groups and, although they would surely be entitled to decent housing even if health were not involved, there is certainly every justification for an active participation in the housing field by health authorities.³ It is only necessary to list the essentials of a healthful home environment to show the close connection: a pure and sufficient supply of water, sanitary sewage disposal, sufficient ventilation, heat, and light, space enough for ordinary family demands, absence of excessive dampness, screening against flies and mosquitoes, freedom from fire and other risks of accidents, adequate playgrounds and sunshine for children. In essence, the committee will deal with all those factors in the home environment which affect physical, mental, or social efficiency.

The varying nature of the housing problem in metropolitan areas, in other large cities, in towns, in rural areas, in different parts of the country, makes any adequate summary of the housing situation today quite impossible in a brief discussion. The urban Real Property Inventory of the Department of

* Read at a Special Session of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

Commerce brings this out very strikingly.⁴ For instance, the percentage of dwelling units with more than one person per room was 40 in Charleston, S. C., and 7 in Portland, Ore. The percentage of units with no private toilets was 49 in Charleston and 2 in Burlington, Vt. Many other housing factors showed wide variations. Although no single, typical picture can be presented, some idea of the situation can be gained from the percentages for the median city for each of several distributions. The survey covered all homes in 64 medium sized and small cities, there being at least one city represented in each state.

Seventeen per cent of dwelling units had more than one person per room.

Eight per cent had no running water.

Nineteen per cent had no inside private toilets.

Twenty-six per cent had no privately used bathtub or shower.

Six per cent were without electricity or gas for lighting.

The median age of the dwellings was from 20 to 25 years.

Thirty-two per cent were multiple.

Seven per cent were vacant at the time of the survey (1934).

Seven per cent had extra families from choice or necessity.

As to rural housing, interesting parallel data are available from the survey of the Bureau of Home Economics of the Department of Agriculture, 1933-1934.⁵ The figures I am using are for the median state in each distribution.

Ninety per cent of dwellings had no inside flush toilets.

Seventy-seven per cent were without a piped-in water supply.

Eighty-five per cent were without bathtubs.

Fourteen per cent were 50 years of age or older.

The data on housing obtained in the National Health Inventory of the Public Health Service (1935-1936) have not been completely analyzed, but what are available form a valuable supple-

ment to the preceding figures. For all cities surveyed 16 per cent of the households were found to have more than 1 person per room, 6 per cent more than 1½ persons per room, and nearly 4 per cent 2 or more persons per room. This index of crowding is used as the only one available, but with a realization of its ambiguity.

It is interesting that the size of the city, *per se*, did not seem to make much difference in the index, the small places showing as much congestion, on the average, as the large.

However, as in the Real Property Inventory, there was wide variation from city to city. At one extreme lies a city with 40 per cent of the families having more than 1 person per room; at the other extreme lies a city with less than 3 per cent of its families in this category. Part of the spread is due to varying proportions of the colored population in different cities; but even for white families, the differences were very marked, about one-third of the cities showing percentages of 20 or more over 1 person per room, and another third with percentages under 10. Equally wide variations are found for the more severe degrees of congestion.

As I said, color was an important factor associated with overcrowding. For the colored families in the southern cities surveyed, 37 per cent had more than 1 person per room, against 20 for the white; 21 per cent had more than 1½ persons per room, against 8 for the white; 16 per cent had 2 or more persons per room, against 6 for the white. In northern cities there was a similar contrast.

Congestion, as measured by this index, was greatest in the South (even for the white families) and lowest on the west coast.

In the income group under \$1,000, which constituted nearly 40 per cent of

the white persons surveyed, 21 per cent of such households showed more than 1 person per room, 8 per cent more than $1\frac{1}{2}$, 5 per cent 2 or more. What can happen in an emergency is well indicated by the degree of overcrowding in the relief population during 1935. For white families, 32 per cent had more than 1 person per room, 14 per cent more than $1\frac{1}{2}$, 8 per cent 2 or more. In the southern cities, congestion was marked in relief families, the figures being 50, 29, and 22, respectively for the white households, and 52, 34, and 27 for the colored.

This statistical description is admittedly inadequate, especially in showing the extent to which housing standards recommended by this committee are not now in general practice; but it does show the wide variations in the problem from city to city and in rural areas, the importance of the housing conditions of the Negro, the widespread existence of sub-standard housing and overcrowding, and the necessity of considering the remodelling of old houses as well as the construction of new—the importance of applying sanitary regulations to existing structures.

Comparison between housing conditions today and those of the past is very difficult. Sanitary conditions have improved, but most studies do not show much improvement in other directions. There is also an ominous note in the unemployment problem. Technological changes, the difficult position of the unskilled worker in competition with machinery, changed trade relations with the rest of the world, make it probable that unemployment will continue as a major problem under present social conditions—and point a direct need for public housing, such as may be expected to develop under the new act passed in the closing days of Congress.

To me, the failure of society appreciably to improve housing conditions

in many years in this country means one thing—that health authorities must coöperate with organized labor in meeting this problem, because the persons who are going to live in the houses are the ones most directly concerned in furthering housing reform. Equally it is a challenge to organized labor to develop an increasing interest and expertness in this field.⁶ The coöperative housing movement in Sweden is of particular relevancy in this connection.

The likelihood of a housing shortage still greater than that in existence now requires a word. If we define *need* as the effective economic demand for houses, we still reach estimates that are really astounding. Terborgh's⁷ estimate for new dwelling units is 3,775,000 by 1941; Brookings Institution⁸ 4,500,000 by the same time; Ernst Kahn's⁹ 9,400,000 by 1945. All of these estimates are carefully worked out, giving consideration to many factors. Will building keep pace with that demand? We know that the number of non-farm homes constructed annually dropped from 933,000 in 1925 to 53,000 in 1934. In 1936 the figure had risen to 270,000. Terborgh believes that the average for the next 5 years is not likely to reach the 750,000 required by the above estimate and that we are therefore probably in for a period of housing deficiency perhaps parallel with the worst period after the World War. It should be emphasized that these estimates have to do solely with the economic demand, not with the social need.

The social need is perhaps best indicated by considering the economic conditions of the population in relation to the cost of housing. In the cities tabulated from the National Health Inventory data, about 40 per cent of the persons were in families receiving incomes of less than \$1,000 per year and 80 per cent were in families receiving less than \$2,000. This was in 1935 and

some improvement is to be expected, but with recovery also go increasing prices. What income is necessary under present conditions to provide decent housing, adequate nutrition, sufficient clothing, proper medical care, is debatable; but it is evident from these figures that a large proportion of the population of this country are not receiving adequate incomes to insure a suitable standard of living. Housing is only one symptom of this maladjustment. It must be attacked as a symptom, but not without realizing that the underlying issue is that of securing a better distribution of income, a higher relative wage scale for the working men, and

greater security against the disastrous effects of depressions.

THE AUTO TRAILER

THE ever present problem of the auto trailer is brought to the fore by the advent of summer. It is true that in a country as large as the United States some sections are concerned with the auto trailers and their inhabitants during the entire year, chiefly the South and Southwest in winter and the North and Northwest in summer, but summer is the great holiday season of the entire year.

As far as we know, no general regulations have been adopted, though some states and some cities have passed laws and ordinances. We are not the only people worried by this new type of migrant. The auto trailer had its origin in Detroit, the great home of the automobile, but has spread to neighboring countries. The Provinces of Canada have found it necessary to adopt regulations. Those of Manitoba¹ passed in 1937 are said to be the basis of those adopted in other parts of Canada. The trailer is known in that country as "auto trailer house" and defined as a "vehicle towed or drawn by an automobile or other means constructed and equipped for the occupation and comfort of persons while traveling from one destination to another."

The great danger from such vehicles is due to the excreta of the inhabitants. Consequently the regulations require that the closets shall be of the removable receptacle type, fly-proof, with proper ventilation and constructed so as to permit proper cleansing and disinfection. The receptacles must be of substantial water-tight metal construction. Sinks and other fixtures used in washing or bathing must also be provided with water-tight metal containers. The use of closets, sinks, wash basins or other fixtures which may permit the discharge of liquid or solid wastes to the ground are strictly prohibited.

The tourist camps, summer resorts, or other locations where trailers are allowed to park shall be adequately provided for the sanitary disposal of all wastes by burial or burning. The use of a common collecting receptacle for the disposal of excreta or other wastes is prohibited. When parked in any city or town where plumbing fixtures and water supplies are provided, the use of the ordinary closets and other such fixtures in trailers is strictly prohibited. Under

no circumstances shall an auto trailer be used as a permanent or occasional place of residence in any city, town, or municipality.

In addition to the regulations mentioned, all trailers and their occupants shall be subject to the provisions and regulations respecting disease control under the Public Health Act.

In England² the health authorities have considerable anxiety over what are known as caravans and caravan encampments. These temporary or movable structures are dumped on sites for use during the summer season and there they remain. Recent decisions as to the liability of such temporary dwellings have placed them clearly under the regulations of the Public Health Act, and they are liable to be dealt with as statutory nuisances as to overcrowding to the prejudice of the health of inmates or if so lacking in proper sanitary accommodations as to give rise to a nuisance prejudicial to health. The Minister of Health is empowered to exempt any camping association which attempts to control its members and to keep the camp site in good sanitary condition. Indeed, so far from bearing down upon the well behaved camper, properly equipped holiday camps and camping sites are fostered in that country.

Some years ago a visiting Englishman described America as a nation on wheels. As we recall it, his impressions were gained from seeing the ordinary automobile. Since that time the number of auto trailers has grown by leaps and bounds and they constitute a real menace to public health along the routes they follow and in the communities where they stop for a longer or shorter time.

WHAT WE OWE TO THE FOREFATHERS

A SHORT time ago we called attention to the mistake of binding one's self too much by authority, and quoted from the wisdom of Oliver Wendell Holmes as well as others on the subject. Another danger has been pointed out most strikingly by Osler,¹ who says: "Of the altruistic instincts veneration is not the most highly developed at the present day, but I hold strongly with the statement that it is the sign of a dry age when the great men of the past are held in light esteem."

We are too apt to forget what we owe to the fathers and should always welcome such reminders. Nothing is more irritating than to hear young men speak lightly of the old doctors. It is no doubt true that with the wonderful discoveries made in many fields and the perfection of diagnostic methods through accurate apparatus, the end results are perhaps in the great majority of cases better than the fathers obtained, but it is a question as to whether or not we are producing as good men as they were. One must view with awe and admiration the country doctors: in America, for example, Drake, born in abject poverty and reared in a log cabin, McDowell, Marion Sims, and Crawford W. Long—to go no further. Abroad, we need only mention as a country doctor, Jenner, who has a sure place in the Hall of Fame; Bright, who boiled the urine of nephritics in a spoon, yet who formulated such a clear clinical and pathological conception of nephritis that little was left for later investigators except amplification;

Bretonneau, who differentiated affections of the throat and stated definitely his doctrine of the specificity of diseases in general and "diphthérie" in particular; and many others who had nothing which we would consider a laboratory today, yet, by their wonderful exactness of observation and well trained powers, unraveled problems in a fashion which has not been bettered even to the present. Among these men we find instances of real originality, though it must be borne in mind that the majority of what we consider great discoveries are really the placing of the capital on the column. The most striking example of this, perhaps, is Harvey's discovery of the circulation of the blood. He himself, thoroughly versed in literature, apparently recognized that it was a great contribution to others in the same field, and though he gave the proof which has withstood the test of time, he had to suppose the capillary circulation, and it remained for Malpighi to demonstrate how the blood made its way from the arteries to the veins. Harvey was all of his life an anatomist, and distrusted authority. He said,² "... because I profess both to learn and to teach anatomy not from books but from dissections, not from the positions of philosophers, but from the fabric of nature."

Medical history is full of rediscoveries of things which have been taught and then forgotten. There are many instances in which "the restatement of an important theory or teaching is almost as significant as its original presentation."³ The truth of this emphasizes the necessity of reading the best works of the fathers. "The more one reads the better medical works of past generations, the more astonished one becomes, and the more humble, too, at what has been known and written and then forgotten."³ Vaughan said: "In my opinion, the present-day medical man, including the epidemiologist, is not as fully conversant as he should be with the history of epidemic diseases. As an illustration I may cite the fact that it took us many months to learn facts about the epidemiology of cerebrospinal meningitis that were demonstrated conclusively by French army surgeons in the first half of the nineteenth century."⁴ "... Is cerebrospinal meningitis a rural disease? Certainly every important contribution to its symptomatology, epidemiology, and pathology, found in American medical literature during the time mentioned comes from a country doctor."⁵

This emphasizes the great service which certain writers are giving to the medical world in the reproduction of masterpieces from the past (see Note). Very few of us have the command of languages, to say nothing more, to read these articles in the original. Osler said: "There is a third class of men in the profession to whom books are dearer than to teachers or practitioners—a small, a silent band, but in reality the leaven of the whole lump. The profane call them bibliomaniacs, and in truth they are at times irresponsible and do not always know the difference between meum and tuum. . . . We need more men of this class, particularly in this country, where every one carries in his pocket the tape-measure of utility. Along two lines their work is valuable. By the historical method alone can many problems in medicine be approached profitably."⁶

At the amazing mass of marvelous revelations which are coming to us through research in practically every field of science, the majority of us can only look and wonder. Few there are in any one branch of science capable of selecting the best material and interpreting it for the average man. This is perhaps especially true in regard to medicine. If for no other reason we need the historian, especially the one who is also a bibliomaniac.

LETTER TO THE EDITOR

TO THE EDITOR:

My attention has been called to two errors in the 1937 Report of the Committee on Water Supply of the Public Health Engineering Section which should be corrected. This report was published in the 1937-1938 *Annual Year Book* of the Association, pages 137-156 inclusive, Supplement to *American Journal of Public Health*, Volume 28, No. 2 (February), 1938.

In the first column, page 145, in a list of 14 states reporting no water-borne outbreaks "during the last 7 years," Mississippi should be deleted and Louisiana substituted.

On page 155, first column, under the sub-title "Outbreaks in Cities Having Filtration Plants," the information submitted to the Committee with regard to the Ft. Wayne, Ind., outbreak of April-Sept., 1934, does not justify the statement . . . "it appears probable that . . . a situation developed similar to the one which caused the explosive outbreak of gastroenteritis in Detroit in 1926, when the quantity of chlorine applied to the filtered water was not sufficient to satisfy the chlorine demand and also permit proper disinfection during a period when a highly polluted raw water was being treated."

The Bureau of Sanitary Engineering of the Indiana State Board of Health

from which the committee obtained information concerning this outbreak reports "our investigation showed conclusively, that the water filtration plant was not responsible for this outbreak."

In the statistical tables given in this report, the Ft. Wayne outbreak of 1934 was properly listed under classification H-3 "Cause of Outbreak Undetermined."

As chairman of the committee which submitted this report, I sincerely regret these errors and request that the above statement of correction be published at an early date in the *American Journal of Public Health*.

For the information of all who read the original report or reprints of it, the committee desires again to emphasize that this report does not deal *only* with water-borne outbreaks involving public water supplies, but with *all* water-borne outbreaks which came to the committee's attention where five or more persons were known to have been ill.

Very truly yours,

ARTHUR E. GORMAN,
Chairman,

Committee on Water Supply (1937)
Public Health Engineering Section
American Public Health Association
June 22, 1938.

PRELIMINARY PROGRAM OF THE
SIXTY-SEVENTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION

KANSAS CITY, MO., OCTOBER 25-28, 1938

THE Annual Meeting Program Committee presents the Preliminary Program of the scientific sessions of the Sixty-seventh Annual Meeting of the American Public Health Association and information concerning meetings of related organizations.

This program is incomplete and perhaps inaccurate in some respects. The affiliations of speakers have been omitted, but will be published in full in the Final Program. Delegates are urged to consult the Final Program, available at the Registration Desk in the Auditorium at the time of the meeting.

Tuesday, 9:30 A.M.

LABORATORY

First Session—Room 500, Auditorium

Address of the Chairman. FRIEND LEE MICKLE, Sc.D.

Report of the Coördinating Committee on Standard Methods.
Chairman, LIEUTENANT COLONEL A. PARKER HITCHENS, M.D.

Report of the Standard Methods Committee on Examination of Water and Sewage. *Chairman, JOHN F. NORTON, Ph.D.*

Report of the Standard Methods Committee on Examination of Dairy and Food Products. *Chairman, ROBERT S. BREED, Ph.D.*

Report of the Standard Methods Committee on Diagnostic Procedures and Reagents. *Chairman, WILLIAM D. STOVALL, M.D.*

Report of the Standard Methods Committee on the Biology of the Laboratory Animal. *Chairman, LIEUTENANT COLONEL RAYMOND A. KELSEY, Ph.D., D.V.M.*

Report of the Standard Methods Committee on Analyzing Frozen Desserts. *Chairman, FRIEND LEE MICKLE, Sc.D.*

Report of the Committee on Biological Products. *Chairman, ELLIOTT S. ROBINSON, M.D., Ph.D.*

Report from the Section Archivist. AUGUSTUS B. WADSWORTH, M.D.

Reports of Representatives of Committees Outside of the Laboratory Section and Other Special Reports.

Section Business.

Tuesday, 9:30 A.M.

HEALTH OFFICERS

First Session—Room 600, Auditorium

The Interests and Problems of the Health Officers' Section. GREGOIRE F. AMYOT, M.D., D.P.H.

Opportunities Under the Federal Housing Acts. C.-E. A. WINSLOW, DR. P.H.

An Analysis of Tenures of Office of Health Officers. JOSEPH W. MOUNTAIN, M.D., and ELLIOTT H. PENNELL.

The Objectives of Health Departments. GEORGE C. RUHLAND, M.D.

VITAL STATISTICS

First Session—Room 400, Auditorium

The Effectiveness of Different Systems of Collecting Vital Statistics Data. J. V. DEPORTE, PH.D.

Discussion. MRS. J. B. COLLIE and RICHARD N. WHITEFIELD, M.D.

The Value of the Vital Statistics Data on Birth and Death Certificates in County Health Work. EARLE G. BROWN, M.D.

Social Security Needs for Vital Statistics Records. I. S. FALK, PH.D.

Discussion. THOMAS W. CHAMBERLAIN.

The Use of Marginal Punch Cards in Tabulating Vital Statistics Data. EVA W. RAMSEY.

System of Record Keeping in Westchester County. MARJORIE T. BELL-OWS.

A Brief Review of the Expected Content of the Demography Exhibit of the New York World's Fair in 1939. HAVEN EMERSON, M.D.

FOOD AND NUTRITION

First Session—Room 501, Auditorium

Present Status of Dental Caries in Relation to Nutrition. NINA SIMMONDS, Sc.D.

The Selenium Problem and Its Relationship to Public Health. IRA A. MANVILLE, M.D., PH.D.

Effect of Environmental Conditions on Incidence of Dental Caries. BION R. EAST, D.D.S.

Some Nutritional Requirements During Growth. P. C. JEANS, M.D.

Nutritional Status of Dextrose. CARL R. FELLERS, PH.D.

Antirachitic Properties of Constituents of Human Milk. (To be read by title only.) ROBERT S. HARRIS, PH.D., and JOHN W. M. BUNKER, PH.D.

Tuesday, 9:30 A.M.

CHILD HYGIENE

First Session—Music Hall, Auditorium

Illnesses Occurring Among Young Children as Revealed in a Nationwide Survey. GEORGE ST. J. PERROTT.

Discussion.

Dental Health Program for the Child. Speaker to be announced.

Discussion.

Preventive Aspects of Orthopedic Service. Speaker to be announced.

Discussion.

Section Business.

PUBLIC HEALTH NURSING SECTION AND AMERICAN SCHOOL HEALTH ASSOCIATION

Joint Session—Little Theatre, Auditorium

Program to be announced.

EPIDEMIOLOGY

First Session—Room 401, Auditorium

Production of Mottled Enamel Halted by a Change in Common Water Supplies. H. TRENDLEY DEAN, D.D.S., and FREDERICK S. MCKAY, D.D.S.

Results of Contact Investigation in Syphilis in an Urban Community. THOMAS B. TURNER, M.D., ABRAHAM GELPERIN, M.D., and JAMES R. ENRIGHT, M.D.

Epidemiology of Leptospirosis. K. F. MEYER, M.D., PH.D.

Epidemiology of Syphilis in New York City. THEODORE ROSENTHAL, M.D., and JOSEPH WEINSTEIN, M.D., M.S.P.H.

The Syphilitic Chancre from the Point of View of the Public Health. WALTER CLARKE, M.D.

Tuesday, 12:30 P.M.

INDUSTRIAL HYGIENE

Luncheon Session—Roof Garden, Hotel Kansas City

DELTA OMEGA

Luncheon Session—Junior Assembly Room, Hotel President

Tuesday, 12:30 P.M.

PUBLIC HEALTH EDUCATION

Luncheon Session—Congress Room, Hotel President

Is the Health Educator Culturally Qualified to Teach? Speaker to be announced.

Tuesday, 2:30 P.M.

PUBLIC HEALTH EDUCATION

First Session—Room 401, Auditorium

BUILDING A HEALTH EDUCATION PROGRAM

The Use of Morbidity and Mortality Statistics. Speaker to be announced.

The Use of Exhibits, Posters and Charts. HOMER N. CALVER.

The Preparation and Use of Printed Materials, Newspaper Publicity, Lectures, Radio and Movies. Speaker to be announced.

Interpreting the Physician and Making Him a Part of a Health Education Program. MARY P. CONNOLLY.

How to Fit a Special Problem Like Syphilis into the Balanced Program. WILLIAM F. SNOW, M.D.

Discussion.

PUBLIC HEALTH ENGINEERING SECTION AND CONFERENCE OF STATE SANITARY ENGINEERS

Joint Session—Little Theatre, Auditorium

Presiding: WARREN J. SCOTT.

House Trailer and Trailer Camp Sanitation. (Report of the Joint Committee on Summer Camps and Roadside Places.) *Chairman,* CARL E. GREEN, C.E.

Existing Systems of Supervision and Control Over Water Supplies and Needed Improvements Thereto. (Preliminary Report of the Committee on Water Supply.) ANSELMO F. DAPPERT.

Irrigation as a Means of Disposal for Sewage Effluents. VICTOR M. EHLERS, C.E.

Discussion. BENJAMIN V. HOWE.

Venting of the Plumbing Drainage System. F. M. DAWSON, M.C.E., and A. A. KALINSKE.

Report of the Joint Committee on Plumbing. *Chairman,* JOEL I. CONNOLLY.

Procedures Recommended for Determining the Extent of Closed Shellfish Areas. (Report of the Committee on Shellfish.) *Chairman,* L. M. FISHER, C.E., D.P.H.

Tuesday, 2:30 P.M.

LABORATORY AND EPIDEMIOLOGY SECTIONS

Joint Session—Music Hall, Auditorium

Presiding: FRIEND LEE MICKLE, Sc.D., and J. A. DOULL, M.D., Dr.P.H.

PERTUSSIS

Essential Problems in Pertussis. HAVEN EMERSON, M.D.

A Controlled Study in Pertussis Immunization. PEARL L. KENDRICK, Sc.D., and GRACE ELDERING, with Statistical Assistance of ANTHONY J. BOROWSKI, Dr.P.H.

An Evaluation of Phase I H. Pertussis Vaccine in Laboratory and Clinic. J. J. MILLER, JR., M.D.

Complement Fixation Studies in Pertussis. THOMAS F. SELLERS, M.D.

Immunity Studies in Pertussis. GEORGE McL. LAWSON, M.D., Dr.P.H.

INDUSTRIAL HYGIENE

First Session—Room 400, Auditorium

SYMPOSIUM ON INDUSTRIAL HYGIENE ADMINISTRATION

Address of the Chairman of the Section: Development of Industrial Hygiene in the United States. J. J. BLOOMFIELD.

Health Maintenance in Industry. CLARENCE D. SELBY, M.D.

Discussion. WILLIAM A. SAWYER, M.D.

Industrial Hygiene Program in a State Health Department. CARL A. NAU, M.D.

Discussion. MANFRED BOWDITCH.

CHILD HYGIENE AND FOOD AND NUTRITION SECTIONS

Joint Session—Room 600, Auditorium

Presiding: D. BREESE JONES, Ph.D.

Clinical Tests of Vitamin Deficiency. (Report of the Committee on Nutritional Problems.) *Chairman,* WALTER H. EDDY, Ph.D.

Malnutrition: A Challenge and Opportunity. H. D. KRUSE, M.D., and FRANK G. BOUDREAU, M.D.

Training of the Public Health Nutritionist. LYDIA J. ROBERTS, Ph.D.

A Comparison of Indices Used in Judging Nutritional Status of School Children. R. M. JENSS, Sc.D.

Some Objectives and Results of Public Health Nutrition in Kansas. PEARL ROBARAUGH, R.N.

The County Public Health Nutrition Project in Georgia. T. F. ABERCROMPIE, M.D.

The Child's Requirement for Calcium and His Ability to Utilize Calcium from Various Sources. JULIA OUTHOUSE, Ph.D.

Tuesday, 2:30 P.M.

PUBLIC HEALTH NURSING

First Session—Room 501, Auditorium

MILESTONES

Milestones of the Past Fifteen Years. DOROTHY DEMING, R.N.

Milestones and Yardsticks. MICHAEL M. DAVIS, PH.D.

Program of the Future. GEORGE C. RUHLAND, M.D.

Preparation of the Nurse of the Future. LEAH M. BLAISDELL, R.N.

AMERICAN ASSOCIATION OF STATE REGISTRATION EXECUTIVES

First Session—Aztec Room, Hotel President

Reports of Committees.

Election of Officers.

Tuesday, 6:30 P.M.

AMERICAN ASSOCIATION OF STATE REGISTRATION EXECUTIVES

Dinner Session—Junior Assembly Room, Hotel President

Tuesday, 8:00 P.M.

FIRST GENERAL SESSION

Music Hall, Auditorium

Presiding: ARTHUR T. McCORMACK, M.D., D.P.H., D.Sc., LL.D., President,
American Public Health Association.

Addresses of Welcome.

Address. THOMAS PARRAN, M.D., D.Sc., LL.D., DR.P.H.

Address. Speaker to be announced.

Announcement of Sedgwick Memorial Medal Award.

Reception to the President and the President-elect.

Dancing—Little Theatre, Auditorium.

Wednesday, 8:00 A.M.

JOHNS HOPKINS UNIVERSITY ALUMNI

Breakfast Session—Trianon Cafe, Hotel Muehlebach

Wednesday, 8:00 A.M.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY ALUMNI

Breakfast Session—Tea Room, Hotel Muchlebach

Wednesday, 9:30 A.M.

HEALTH OFFICERS

Second Session—Music Hall, Auditorium

Developments in the New York State Tuberculosis Program. ROBERT E. PLUNKETT, M.D.

SYMPOSIUM ON VENEREAL DISEASE CONTROL

The Results of Venereal Disease Control in Toronto. GORDON BATES, M.D.

The Control of Venereal Diseases in a Southern Rural Area. L. E. BURNEY, M.D.

Blood Tests for Syphilis "Boiled Down." JOHN F. MAHONEY, M.D.

LABORATORY

Second Session—Room 500, Auditorium

Presiding: WILLIAM D. STOVALL, M.D.

DIAGNOSTIC METHODS

Modifications of Gram's Technic with a New Differential Counterstain.

(a) For Direct Smear. (b) For formalin-fixed tissue. SARA A. SCUDDER.

Laboratory Diagnosis of Rabies. THOMAS F. SELLERS, M.D.

Evaluation of Technical Procedures for the Examination of Specimens for Evidence of Enteric Disease. MARION B. COLEMAN.

Further Observations of the Primary Isolation of Tubercle Bacilli by Cultural Method. A. L. MACNABB, D.V.M.

Serological Tests in the Diagnosis of Syphilis. ELIZABETH MALTANER.

LABORATORY

Third Session—Room 201, Auditorium

Comparative Study of Bacteriological Examinations of Restaurant Utensils. OTTO P. BEHRER.

Spinal Fluid Changes in Neuro-Syphilis. CARL LANGE, M.D.

A Comparative Study of the Mouse and Guinea Pig Inoculation—Methods in the Diagnosis of Rabies. S. E. SUTKIN, and JOSEPH C. WILLIET, D.V.M.

Fifteen Years of the Standard Kahn Test. RUDIN L. KAHN, Sc.D.

Experimental Infection of *Dermacentor Andersoni* Stiles with the Virus of Lymphocytic Choriomeningitis. ALFRED MILLER and HOWARD J. SHAUGHNESSY, Ph.D.

Wednesday, 9:30 A.M.

PUBLIC HEALTH ENGINEERING

First Session—Room 400, Auditorium

SYMPOSIUM ON THE EXPANDING FIELD OF PUBLIC HEALTH ENGINEERING

The Projection of Public Health Engineering Service in New York State. W. H. LARKIN, C.E.

Districting New Mexico for Sanitation. PAUL S. FOX, C.E.

Engineering Service in City Departments of Health. (Report of the Committee on Municipal Public Health Engineering.) *Chairman*, SOL PINCUS, C.E.

Organization for Public Health Engineering Service in a Rural-Urban Area. WILLIAM T. INGRAM.

(Session continued in the afternoon.)

CHILD HYGIENE

Second Session—Room 401, Auditorium

MATERNAL AND CHILD HEALTH

Use of Birth and Death Records as a Method in Controlling Early Infant Deaths. THOMAS J. DUFFIELD.

Discussion.

Control of Rickets Among Infants Living in Large Cities. JULIUS LEVY, M.D.

Discussion.

Obstetric Service in a Rural Community. Speaker to be announced.

Discussion.

Advances Made in the Federal Program for Maternal and Child Health. MARTHA M. ELIOT, M.D.

Discussion.

AMERICAN ASSOCIATION OF STATE REGISTRATION EXECUTIVES

Second Session—Junior Assembly Room, Hotel President

Reports of Committees.

Confidentialness of Records. LEONARD V. PHELPS and FRANK MORRISON.

Wednesday, 9:30 A.M.

PUBLIC HEALTH EDUCATION

Second Session—Little Theatre, Auditorium

SYMPOSIUM ON OUTPOSTS OF RESEARCH AND NEW FACTS FOR THE HEALTH EDUCATOR

Introduction.

Why the Health Educator Should Keep Abreast of Developments in Medicine and How He May Do That. IAGO GALDSTON, M.D.

Mental Hygiene in the Past Decade. Speaker to be announced.

Advances in Our Knowledge of Nutrition. FRANKLIN C. BING, M.D.

Newer Methods of Dealing with Prevention, Detection, and Control of Pneumonia. Speaker to be announced.

Newer Research Findings for Dealing with Syphilis and Gonorrhea. WALTER CLARKE, M.D.

Discussion.

PUBLIC HEALTH NURSING

Second Session—Room 600, Auditorium

THE STATE HEALTH DEPARTMENT AND ITS RELATION TO ALL PUBLIC HEALTH NURSING WITHIN THE STATE

The State Public Health Nursing Service as Seen by a Nonofficial Agency. ALMA C. HAUPT, R.N.

The State Public Health Nursing Unit and Its Relation to the Special Services. JANE D. NICHOLSON, R.N.

The Private Public Health Nursing Agency and Its Relationship to the State Public Health Nursing Service. ALEXANDRA MATHESON, R.N.

Interrelationships—University Courses of Study and State Nursing Service. Speaker to be announced.

EPIDEMIOLOGY

Second Session—Room 501, Auditorium

Rocky Mountain Spotted Fever and Tick Survey in Iowa. CARL F. JORDAN, M.D., C.P.H.

Nosocomial Infections in an Infants' Hospital. ARTHUR P. LONG, M.D., CHARLES F. MCKHANN, M.D., and LUCILE L. CHENEY.

Paratyphoid Fever in Massachusetts. ROY F. FEEMSTER, M.D., DR.P.H.

Probable Typhoid Carrier Incidence in Mississippi. A. L. GRAY, M.D.

Discussion. F. C. FORSBECK, M.D.

Factors Influencing Nonspecific Resistance to Infection. CHARLES F. CHURCH, M.D.

Wednesday, 12:30 P.M.

FOOD AND NUTRITION

Luncheon Session—Aztec Room, Hotel President

Report of the Committee on Bioassay Methods for Vitamin D Milk.
Chairman, HENRY T. SCOTT, PH.D.

Report of the Committee on Participation in Standard Methods.
Chairman, FRED C. BLANCK, PH.D.

Report of the Committee on Fellowship and Membership. *Chairman, ABRAHAM LICHTERMAN, PHAR.D.*

PUBLIC HEALTH NURSING

Luncheon Session—Congress Room, Hotel President

Presiding: PHYLLIS M. DACEY, R.N.

An Engineer Looks at Public Health Nursing. ABEL WOLMAN, DR.ENG.

Section Business.

Wednesday, 2:30 P.M.

PUBLIC HEALTH ASPECTS OF MEDICAL CARE

Special Session—Music Hall, Auditorium

Program to be announced.

VITAL STATISTICS SECTION AND AMERICAN ASSOCIATION OF STATE REGISTRATION EXECUTIVES

Joint Session—Junior Assembly Room, Hotel President

The New Form of Certificate. HALBERT L. DUNN, M.D., PH.D.

Discussion. IRVA C. PLUMMER and WILLIAM R. TRACEY.

Testing Completeness and Accuracy of Registration of Births and Deaths.

(a) Results of Experience with Different Methods of Testing Registration in Texas Under Varied Local Conditions. W. A. DAVIS, M.D.

(b) A Comparison of the Effectiveness of Different Methods of Testing Registration in the Same Area in Maryland. ARTHUR W. HEDRICH, SC.D., FRANCIS D. RHODES, and JOHN COLLINSON, M.D., DR.P.H.

Discussion. P. K. WHELPTON and JO C. ROSE.

The Coroner's Situation. S. R. GERBER, M.D.

Discussion. R. T. STIMPSON, M.D.

Wednesday, 2:30 P.M.

LABORATORY AND FOOD AND NUTRITION SECTIONS

Joint Session—Room 600, Auditorium

Presiding: FRIEND LEE MICKLE, SC.D., and FREDERICK W. FABIAN, PH.D.

SYMPOSIUM ON FROZEN DESSERTS

What Are Frozen Desserts? FREDERICK W. FABIAN, PH.D.

The Quality of Gelatin as a Stabilizer in Ice Cream. JAMES GIBBARD.

Sanitation of Products Added to Frozen Desserts. P. H. TRACY, PH.D.

Sediment Tests in Frozen Desserts. MILTON E. PARKER.

Public Health Aspects of Fruits, Nuts, Colors and Extracts. MARTIN J. PRUCHA, PH.D.

Notes on Ice Cream Analysis. A. H. ROBERTSON, PH.D.

Brief Reports of Associate Referees:

Eggs. LAWRENCE H. JAMES, PH.D.

Sugar. HARLOW H. HALL.

Dry Milk. PAUL S. PRICKETT, PH.D.

Condensed and Evaporated Milk. P. A. DOWNS, PH.D.

LABORATORY

Fourth Session—Room 500, Auditorium

Presiding: THOMAS F. SELLERS, M.D.

TYPHOID FEVER

Evaluation of Procedures for Isolation of Typhoid Bacilli in Public Health Laboratories. HERBERT E. MCDANIELS, PH.D.

Efficacy of Immunization in an Acute Water-Borne Outbreak of Typhoid Fever. CHARLES D. BOWDOIN, M.D., C.P.H.

Progress Report on Studies of: Strains of *Eberthella Typhosa* for the Preparation of Vaccine, Duration of Immunity, and Results of Revaccination. LIEUTENANT COLONEL GEORGE C. DUNHAM, M.D.

PUBLIC HEALTH ENGINEERING

Second Session—Room 501, Auditorium

SYMPOSIUM ON THE EXPANDING FIELD OF PUBLIC HEALTH ENGINEERING

(Continued from morning session)

Potentialities of Public Health Engineering in Relation to the Social Security Act. ROY J. MORTON.

Educational Opportunities for the Public Health Engineer and Sanitarian. HARRY E. MILLER.

Supplementary Education of Milk Inspectors. (Report of the Joint Committee on Milk Supply.) *Chairman,* WALTER VON D. TILDENMAN, M.C.E.

The Rôle of the Public Health Engineer in Public Health Administrative Work. MURRAY P. HOEWOOD, PH.D.

Discussion. ARTHUR WOLMAN, DR.ENG.

Wednesday, 2:30 P.M.

INDUSTRIAL HYGIENE

Second Session—Room 401, Auditorium

CONTROL OF INDUSTRIAL HAZARDS

The Safe Operation of Degreasing Tanks Employing Trichlorethylene.

W. B. HARRIS, CH.E., C. B. FORD, and F. A. PATTY.

Discussion. HENRY FIELD SMYTH, M.D., DR.P.H.

Industrial Hygiene Codes. JAMES R. ALLAN.

Discussion.

The Effect on Health of Gases Produced by the Electric Arc. LEROY

W. LATOWSKY.

Discussion.

Wednesday, 6:30 P.M.

VITAL STATISTICS

Anniversary Dinner—Congress Room, Hotel President

PUBLIC HEALTH ENGINEERING AND CONFERENCE OF STATE SANITARY ENGINEERS

Annual Engineers' Stag Dinner—Banquet Hall, Hotel Muehlebach

PUBLIC HEALTH EDUCATION

Dinner Session—Trianon Cafe, Hotel Muehlebach

Closed Session—For Fellows of the Section Only

Address. Speaker to be announced.

Wednesday, 8:00 P.M.

PUBLIC MEETING

Sponsored by the Local Committee, the Jackson County Health
Forum, and the Jackson County Medical Society

Special Session—Music Hall, Auditorium

Presiding: EDWIN H. SCHORER, M.D., DR.P.H.

Vitamins. E. V. MCCOLLUM, PH.D.

Address. ARTHUR T. MCCORMACK, M.D., D.P.H., D.Sc., LL.D., President,
American Public Health Association.

Thursday, 8:00 A.M.

THE AMEROPS

Breakfast Session—Music Room, Hotel Muehlebach

Thursday, 8:00 A.M.

HARVARD UNIVERSITY ALUMNI

Breakfast Session—Trianon Cafe, Hotel Muehlebach

YALE UNIVERSITY ALUMNI

Breakfast Session—Tea Room, Hotel Muehlebach

Thursday, 9:30 A.M.

HEALTH OFFICERS AND PUBLIC HEALTH NURSING
SECTIONS

Joint Session—Music Hall, Auditorium

Is the Health Officer Fulfilling His Responsibilities in Relation to the Nursing Program? GRACE ROSS, R.N.

A Critical View of Nurses and Nursing Programs. FELIX J. UNDERWOOD, M.D.

Discussion. HUNTINGTON WILLIAMS, M.D.

Administrative Policies that Interfere with Effective Public Health Procedures. MAYHEW DERRYBERRY, PH.D.

A Program of Maternal Care in a Rural County. EARL P. BOWERMAN, M.D., and W. FRANK WALKER, DR.P.H.

LABORATORY

Fifth Session—Room 201, Auditorium

Presiding: JOHN F. NORTON, PH.D.

WATER AND SEWAGE

Uses and Abuses of Biochemical Oxygen Demand. M. STARR NICHOLS, PH.D.

Symposium on Slow Lactose Fermenters. Speakers to be selected.

LABORATORY

Sixth Session—Room 401, Auditorium

Correlation of Laboratory Studies on Diphtheria Immunization Methods and Their Possible Practical Application. F. G. JONES.

Mass Immunization against Diphtheria with Sordelli's Activated Toxoid and Contact Immunization. ALBERTO P. LEON, M.D., M.P.H.

Diphtheria in Tennessee. C. B. TUCKER, M.D., C.P.H.

The Diphtheria Immunization Studies in Saginaw. V. K. VOLE, M.D., and W. E. BUNNEY, PH.D.

Subject and Speaker to be announced.

Subject and Speaker to be announced.

Thursday, 9:30 A.M.

VITAL STATISTICS

Second Session—Room 500, Auditorium

Objectives of the Section. JESSAMINE S. WHITNEY.

Report of the Committee on Accident Statistics. *Chairman*, ROBERT J. VANE.

Report of the Committee on Forms and Methods of Statistical Practice. *Chairman*, ARTHUR W. HEDRICH, Sc.D.

Report of the Committee to Study Death Certification. *Chairman*, MARJORIE T. BELLOWS.

Report of the Committee on Residence Allocation. *Acting Chairman*, ELIZABETH PARKHURST.

The Vital Statistics of the Pueblo Indians. J. H. WATKINS, Ph.D., S. D. ABERLE, M.D., and E. H. PITNEY.

A Time Study of Morbidity and Mortality in the United States Navy. J. M. WHEELIS, JR., M.D.

Section Business.

PUBLIC HEALTH ENGINEERING

Third Session—Room 400, Auditorium

The Measurement of Sanitary Ventilation. Part II. WILLIAM F. WELLS.

Recent Developments in Waterways Pollution Control. (Report of the Committee on Waterways Pollution.) *Chairman*, LOUIS F. WARRICK, Ch.E.

The Occurrence, Pathological Aspects and Treatment of Fluoride Wastes. M. STARR NICHOLS, Ph.D.

Practical Procedures and Limitations in Present-Day Smoke Abatement. HARRY B. MELLER.

Progress Report of the Committee on Industrial Sanitation. *Chairman*, CHARLES L. POOL.

FOOD AND NUTRITION

Second Session—Room 501, Auditorium

The Food Control Exhibit at the New York World's Fair, 1939. SAMUEL C. PRESCOTT, D.Sc.

The Nutrition Exhibit at the New York World's Fair, 1939. WALTER H. EDDY, Ph.D.

Symposium on Public Health Problems in Packing Meat and Shellfish. Speakers to be announced.

Thursday, 9:30 A.M.

CHILD HYGIENE SECTION AND AMERICAN
SCHOOL HEALTH ASSOCIATION

Joint Session—Little Theatre, Auditorium

SYMPOSIUM ON NEXT STEPS IN SCHOOL HEALTH SERVICES

Program to be announced.

EPIDEMIOLOGY

Third Session—Room 600, Auditorium

Results Obtained in the Program of Tuberculin Testing of Persons Residing in Congested Areas of a Large City. BRUCE H. DOUGLAS, M.D., and GAUS E. HARMON, M.D.

Epidemiology of Epidemic Encephalitis in California. HARLIN L. WYNNS, M.D., and CARL J. HAWLEY, M.D.

Preliminary Observations on the Epidemiology of Mental Disease in the Eastern Health District, Baltimore. ALLEN W. FREEMAN, M.D.

Pneumonia Control Program in Pennsylvania. EDITH MACBRIDE-DEXTER, M.D.

The Incidence of Vincent's Infection in the School Children in Kansas. L. R. KRAMER, D.D.S.

Thursday, 12:15 P.M.

AMERICAN SCHOOL HEALTH ASSOCIATION

Luncheon Session—Junior Assembly Room, Hotel President

COMMITTEE LUNCHEONS

Committee on Membership and Fellowship.

Committee on Meetings and Publications.

Committee on Professional Education.

Committee on Methods and Materials in Health Education.

Committee on School Health Service Practice.

Thursday, 12:30 P.M.

PROFESSIONAL EDUCATION

Special Luncheon—Congress Room, Hotel President

Address. EDWARD S. GODFREY, JR., M.D.

Address. PEARL McIVER, R.N.

Thursday, 2:00 P.M.

AMERICAN SCHOOL HEALTH ASSOCIATION

General Session—Room 501, Auditorium

Thursday, 2:30 P.M.

AMERICAN ASSOCIATION OF STATE REGISTRATION
EXECUTIVES

Third Session—Aztec Room, Hotel President

Reports of Committees.

International Coöperation in Vital Statistics. WILLIAM R. TRACEY.

Inauguration of Officers.

Thursday, 7:00 P.M.

SECOND GENERAL SESSION

Banquet—Arena, Auditorium

Presiding: ARTHUR T. McCORMACK, M.D., D.P.H., D.Sc., LL.D., President,
American Public Health Association.

Address of the President-elect. ABEL WOLMAN, DR.ENG.

Presentation of Forty Year Membership Certificate.

Announcement of Health Conservation Contest Awards.

Friday, 8:15 A.M.

AMERICAN SCHOOL HEALTH ASSOCIATION

Breakfast Session—Tea Room. Hotel Muehlebach

Governing Council Meeting.

Friday, 9:30 A.M.

KANSAS CITY ANNUAL MEETING

TO public health workers in Kansas City, October 25-29 are "red letter days" on the fall calendar. When Mr. and Mrs. Delegate pack their bags for the 67th annual meeting of the American Public Health Association, they should come prepared for sports, sight-seeing, and a wealth of scientific information. As chief host, Kansas City's Health Director, Dr. E. H. Schorer, has arranged a varied entertainment program. From a professional standpoint, 8 optional tours have been arranged, to give not only a composite picture of Kansas City's health program, but also an opportunity to see something of the city itself.

Scientific sessions on Tuesday and Wednesday evenings, October 25 and 26, will be held in the colorful Music Hall of the Kansas City Municipal Auditorium. The business session will be followed by dancing in the Little Theatre. Guest speakers for the public meeting on Wednesday evening, October 26, will be President Arthur T. McCormack, Health Commissioner of Louisville, Ky., and Dr. E. V. McCollum, Professor of Bio-chemistry at Johns Hopkins University, Baltimore, Md.

The Annual Banquet of the Association will be held on Thursday, October 27, in the vast main arena of the Auditorium. Entertainment will include various tribal dances by students from Haskell Institute, a federal training school for Indians at Lawrence, Kans.; music by a Negro choir of 500 members; and a 12 minute demonstration of color lighting from the huge

dome ceiling of the Arena, where all of the various lighting effects obtainable in a modern theatre may be produced.

Between business sessions, banquets, luncheons, and other entertainment features, golf enthusiasts will be extended the courtesy of the sportiest of Kansas City's private courses. Ample time will be allowed for individual entertainment and for inspection of Kansas City itself. The 8 optional tours, as arranged by Chairman E. L. Filby, have been planned with this thought in mind, and with the thought that public health as affected by the manufacture of food products, meat inspection, the municipal water supply, and model dairy farms, may be studied at first hand. As outlined below, each of the tours includes at least one industrial or food plant, municipal water departments, or hospitals, closing with a tour of Kansas City's William Rockhill Nelson Gallery of Art, and the well known Country Club residential section.

Trip 1—Loose Wiles Biscuit Company, Armour Packing Plant, a tour of the Central Industrial Area, Country Club Residential Section, Nelson-Atkins Gallery of Art, and the Municipal Hospital group.

Trip 2—Swift Packing Plant, Southwest Milling Company, through Country Club Plaza and residential section, to Nelson-Atkins Gallery of Art, and Municipal Hospital group.

Trip 3—Cudahy or Wilson Packing Plants, west to Colgate Palmolive Peet Soap Manufacturing plant, through central industrial area, returning to Country Club Plaza and residential section, Nelson-Atkins Gallery of Art, and Municipal Hospital group.

Trip 4—To Municipal hospitals, and Union Station Plaza, with stops at the Liberty

Entrance to Longview Farm

Memorial, a combined monument and building erected in 1926 in honor of Kansas City's World War dead; south over the winding drives of Kansas City's Country Club Plaza and residential sections; returning by way of Nelson-Atkins Gallery of Art, University of Kansas City, Kansas City Art Institute, and Rockhill residential section, to Children's Mercy Hospital for inspection tour.

Trip 5—To Larrabee Flour Mills, and Municipal Waterworks in Missouri and Kansas, returning by way of Fairfax and Municipal Airports to hotel headquarters. The Kansas City, Mo., water purification works is a modern 100,000,000 gallon per day purification plant. The raw water which is taken from the Missouri River carries a large amount of suspended matter, and at times as much as 619 tons of suspended matter is removed per hour at this plant. The purification process consists of pre-sedimentation, coagulation, chlorination, and filtration.

Trip 6—For those who register in advance, a 40 mile trip to Leavenworth, Kans., site of Federal Narcotics Bureau, Federal Penitentiary, and Old Soldier's Home. Within the walls of the federal prison, 3,103

men are gainfully employed in one of the various units which include an engine room, barber shop, broom factory, carpenter shop, shoe factory, tailor shop, hospital, and two farms. Of these, the engine room, barber shop, hospital, tailor shop, and farms are operated solely for the use of prisoners. Industries featured at the prison are the carpenter shop, broom shop, and shoe factory, finished products of which are sent to other federal bureaus to supply the Army and Navy, federal training schools for Indians, and other federal prisons.

Trip 7—Tuberculosis Hospital at Leeds, 10 miles out of Kansas City.

Trip 8—For those who register in advance, a 10 mile trip to Longview Farm, a 1,700 acre colony, with its own 20 acre lake, private water supply, chapel, modern dairy, greenhouses, and fine horses. It is operated by Mrs. Lula Long Combs, daughter of the late R. A. Long, who, while building a vast lumber kingdom, became interested in breeding fine horses. Interesting to visitors is Mrs. Combs's array of ancient hacks and rigs, complete with "driving apparel" from the Gay Nineties to the present day.

Longview's modern dairy contains 525 Guernseys, Holsteins, and Jersey cattle, which

Kansas City Tuberculosis Hospital

provide milk which is bottled and moved on conveyer belts to waiting dairy trucks. The greenhouse contains 35,000 roses and 25,000 gardenias, as well as a few orchids, carnations, and other cut flowers which are sold to wholesale florists. Of the 1,700 acres acquired in 1911-1912, approximately 100 acres are landscaped, 1,200 in cultivation devoted to raising of feed, and the remainder in pastures.

Second only to interest in convention activities and opportunities for recreation is a professional interest in the general health program being carried on in the host city.

Public health in Kansas City is both tax supported and voluntary, the latter being carried on through the health division of the Council of Social Agencies. The former is that which is done through the Board of Education, and the City Health Department.

The City Health Department, under the direction of Dr. E. H. Schorer, in addition to the divisions ordinarily

found in a health department, includes a division of hospitals. These are the municipal General Hospital for the white, the General Hospital for the colored, and the tuberculosis and isolation hospitals for the white and colored. The staffs of the general hospitals are voluntary, and only members of the Jackson County Medical Society at the white hospital, and the Kansas City Medical Society for the colored are eligible. As 10 per cent of Kansas City's population is Negro, the general hospital for colored has a definite place in the local health program. Fifty per cent of the Negro children born in Kansas City in 1937 were born here.

The Tuberculosis Hospital at Leeds, Mo., is one of the few municipal hospitals in the United States for the treatment of tuberculosis. Patients are admitted through the tuberculosis service in cooperation with the Kansas

City Tuberculosis Society, and surgical treatment is given cases transferred from the state and county sanatorium. It has a modern surgical pavilion, completed within the last 2 years, where such operations as phrenicectomy, thoracoplasty, and pneumolysis are most frequently performed. The hospital's combined plant has been checked by many of the country's foremost phthisiologists and proclaimed a complete and modern working unit for the treatment of all types of pulmonary tuberculosis.

Out-patient departments are maintained at both of the General Hospitals, including a social service department, which coöperates with the Council of Social Agencies. All patients, except some at the Tuberculosis Hospital, are registered at the Central Index of Indigency.

Health work in the schools is under the Department of Health and Physical Education. Besides the health instruction given in the classrooms as part of the school curriculum, and the home care by the school nursing staff, special schools and classes are provided for under-privileged, physically handicapped children. There are 15 schools which have open air rooms for children who are contacts with tuberculosis, or who are predisposed to tuberculosis, or, in special cases, children with heart trouble or who are undernourished. There are also a trachoma school, a school for the deaf, a sight saving class in one of the schools, and a school for crippled children.

Diphtheria immunization during the past 4 years has been largely under the control of the medical profession of Kansas City, the Health Department supplying the immunization material. As a result of diligent effort, there were no deaths from diphtheria in 1936 and 1937, and the number of cases per year has been so markedly decreased

that only 63 cases were reported last year in a population of 425,000.

The Council of Social Agencies brings together the various volunteer health agencies in Kansas City. The City Health Department and the Jackson County Medical Society also have representation on this Council. In addition to providing educational programs, this division also has special committees to study health needs of the community, with an eye to possible elimination of duplication or unnecessary services. Under this council are the health agencies supported wholly or partially by the Allied Charities Fund through voluntary contributions, the Red Cross, the Health Conservation Association, the Children's Bureau, Visiting Nurse Association, and the various hospitals, clinics, and health centers.

The Health Conservation Association is composed of a federation of volunteer health educational organizations. Component agencies include the Tuberculosis Society, Mental Hygiene Society, Cancer Control Committee, Child Guidance Clinic, Social Hygiene Society, Heart Committee, Dental Hygiene Committee, the Milk Committee, and the Pneumonia Committee. All of these organizations are housed in one central office for administrative purposes, and each carries on its own work, in addition to contributing to the joint health program of the association. Integration of programs and policies is provided by a board of directors, made up of 3 representatives from each component agency, together with 10 directors representing the public.

The Children's Bureau conducts an annual health canvass, with the aid of several hundred volunteers. Last year, 8,599 preschool children were examined at various centers located in public school buildings. Of this num-

ber, 5,156 were found to have defects needing attention, and the parents were referred to their physicians. Year round health educational work is done through special health institutes and group meetings. The Children's Bureau works in close coöperation with the City Health Department, the Jackson County Medical, and the Kansas City Dental Societies.

The Visiting Nurse Association, with its staff of 42 nurses, provides skilled nursing care to patients in their own homes, and endeavors to meet the needs of those who do not find it possible to employ a full-time nurse in the home. The full cost of a nursing visit is \$1.00 (maternity \$1.25), and the nurse is expected to collect as much of this sum as possible. Part pay service is available for those patients who wish to pay something, but who cannot pay the full cost of this service, and free health services are given to those unable to pay, made possible by the allotment received from the Charities

Fund. The services available include general nursing, maternity nursing (prenatal and postnatal care), communicable disease nursing, tuberculosis nursing, child welfare service, and infantile paralysis service. This last consists of muscle training and massage, given in the patient's home, at the R. J. Delano School for crippled children, and at the Attucks School for Negro children. The association also supplies nursing service to 15 affiliated organizations. Last year the nurses made 98,494 visits to 18,717 patients, each nurse averaging 8.7 visits per day.

The Wheatley-Provident Hospital is one of 16 hospitals having an "A" rating among Negro hospitals accredited by the American College of Surgeons. It is also the only approved hospital to which moderately large sums have been given, that is owned, operated, and staffed by Negroes, and the only hospital in Greater Kansas City having accommodations for colored pay patients in private or semi-private rooms,

Lake at Longview Farm—10 miles outside Kansas City

Kersey Coates Drive, Kansas City

as well as wards. It maintains a children's ward for Negro children, similar to Children's Mercy Hospital. Last year the in-patient department cared for 463 adults and 125 children, while the clinic served 3,194 different individuals.

Children's Mercy Hospital is one of Kansas City's beloved institutions, and its name is synonymous with that of the late Dr. Katherine B. Richardson. It was founded more than 40 years ago for sick and crippled children whose families cannot afford to pay for hospital care. Last year the hospital cared for 2,344 different children, or an average of 195 per month, in the in-patient department; while in the out-patient department, 15,528 different children made 22,006 visits to the clinic, or an average of 1,571 visits per month.

Clinics and Dispensaries—People who cannot afford the paid services of physicians when sick or injured, may

be treated in one of the several private clinics, maintained in part or entirely by allotments from the Kansas City Charities Fund. Altogether last year these clinics (exclusive of Children's Mercy Hospital and the Wheatley-Provident Hospital clinics) served 19,909 individuals for 62,857 visits. While a small fee may be charged for registration or drugs, no patient is turned away for lack of funds; on the other hand, proper investigation is made to prevent imposition. Many physicians and dentists give generously of their time both in the clinics and the hospitals.

Of these clinics, the Alfred Benjamin Dispensary and the West Side Health Center, or Richard Cabot Club will be mentioned. The Alfred Benjamin Dispensary is perhaps one of the best equipped charitable institutions in the country. It also houses the child guidance clinic of the Mental Hygiene Society.

The West Side Health Center is located on the once fashionable "Quality Hill," now more appropriately known as "Quantity Hill." It is a general health clinic.

The University of Kansas Hospital, located in Kansas City, will be of interest to public health workers because of the out-patient department, which serves patients on either side of the state line, the attendance exceeding 70,000 visits annually. The hospital has a bed capacity of 250 beds, and is owned and controlled by the Medical School. Eighty-five per cent of the beds are available for teaching purposes, in spite of the fact that the hospital is 80 per cent self supporting.

The hospital is located 2 miles southwest of the Municipal Auditorium, at 39th Street and Hudson Road, occupying a new site on the Kansas side of this metropolitan area. The newly developed medical plant is situated atop a hill, occupying 15 acres of

land, including a group of 4 new buildings of modern construction: the hospital, the nurses home, the medical school, and the power plant. Recently completed are the children's pavilion, the new clinic building or out-patient building, and the Hixon laboratory devoted exclusively to research. The first 1½ years of the medical course are given at the University of Kansas at Lawrence, Kans., 40 miles west of here, where the departments of anatomy, physiology, bio-chemistry, and bacteriology are located. The last 2½ years are given in the Kansas City division of the medical school.

The foregoing is not intended to be comprehensive as regards public health work in Kansas City. Neither can it be said to do justice to Kansas City's many attractive features for amusement to visitors. Delegates will find Kansas Citians eager to make this meeting a most successful and pleasurable one for all who attend.

APPLICATION FOR HOTEL ACCOMMODATIONS

This application is reprinted for your convenience in making hotel reservations. The Hotels Muehlebach, President, and Kansas Citian are headquarters. Mail application to the address below and not to the hotel of your choice.

In making application for hotel accommodations, it is necessary that four choices of hotels be indicated and that a reasonable range of rates desired be shown. Whenever possible, arrangements should be made for occupancy of double rooms; only a limited number of single rooms are available.

HOUSING COMMITTEE
1028 Baltimore Avenue
Kansas City, Missouri

Date.....

Please make hotel reservations noted below:

Hotel	First Choice	Hotel	Third Choice
Hotel	Second Choice	Hotel	Fourth Choice
...Double Rooms with bath for persons.Rate desired \$... to \$... per day			
...Single Rooms with bath.....Rate desired \$... to \$... per day			
...Suites—Parlor, ...Bedroom(s) with bath for ... persons. Rate desired \$... to \$... per day			
Special Instructions

PUBLIC HEALTH EDUCATION*

Consultation at Kansas City—
Please make yourself known at the desk in Health Education and Publicity Headquarters.

Kindly come prepared to share your ideas and your experiences. And come loaded with questions and problems.

The editor of this department invites discussion with all concerned with health education. Workers with long experience will welcome opportunities for answering questions.

Free Material for Kansas City—
Please do not send to New York free material intended for distribution at Kansas City in October.

Kindly ask for the correct mailing or shipping address.

Wanted! If Announced in Advance!—We want for display at Kansas City in October materials on public health education, college or school health education.

Descriptions, outlines, or reports of health education done by departments or associations, colleges, schools.

Topics, outlines, and full copies of talks, or various forms of broadcasts will find interested readers.

Photographs or drawings, posters or placards, projection material, dramatizations, 3 dimension exhibits, window displays—all will be given adequate space.

Much of the above could be mounted on large cards, or in portfolios or scrapbooks.

Please be sure to report long in advance for assignment of space and for specific shipping or delivery instructions.

Correct addressing and deliveries will do away with many troubles behind the scenes.

Two Copies for Kansas City—
Please send 2 copies each of whatever you have, printed or mimeographed, to be included with other classified materials for display at Kansas City in October.

Address to the editor. See footnote on the first page of this department.

Roll Posters for the Receivers—
Did you ever receive a poster in a roll, and try to flatten it for wall display? And have you rolled and rolled, and not always succeeded in making the top and bottom rest against the wall?

And while you are struggling with that poster did you wonder about the people who put out posters and fail to visualize the troubles they inflict upon the innocent receivers?

Are You Interested in Meetings?
In Discussion?—Gatherings of 3 to 30, to 300 or even more, are among the chief channels for health education. Conferences or committee meetings almost lead as a method in planning and organizing public health activities.

There are ways leading to better meetings of all types. Discussion in committees and elsewhere can be satisfying and fruitful. We are working on meeting practices and discussion techniques. Please tell us about your experiences and observations. Your help will be appreciated.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to
Ewart G. Routzahn, 130 East 22d St., New York, N. Y.

MATERNITY CENTER POSTERS

Maternity Care Made Graphic— Effective examples of poster production by the silk screen process are offered by the Maternity Center Assn., 1 E. 57th St., New York, N. Y. Set of 5, 50 cents. Each of the set, illustrated on this page, is 8 by 24 inches; 3 are white on blue, 2 are white on red.

The instructions say:

These posters are designed for use in maternity clinics, mothers' classes, health centers, nursing associations, community exhibits, etc. Their purpose is to teach expectant mothers and fathers important points of maternity care in a clear and simple manner.

They should be hung at eye level about 4 inches apart. If the color of the wall on which they are placed detracts from their value, they may be hung against a sheet of white paper, approximately 10 feet long and 40 inches wide. White wrapping paper, crepe paper, or corrugated paper looks well.

Journal for June, 1938—References in *American Journal of Public Health*, June, 1938:

"Medical Writing" (p. 705) emphasizes a condition and suggests a remedy.

"Nutrition Program in a State Health Department," by Morris (pp. 718-722) describes a school year in a Delaware county:

"what we did, then how we did it, and finally why we did it."

Be sure to read "An American Museum of Health" (pp. 771-773).

"Newer Knowledge of Poliomyelitis" (p. 776) is a quotation of

especial importance to all who deal with public opinion.

In "Books and Reports" see "How To Be a Convincing Talker" (p. 784), and "How To Use Pictorial Statistics" (p. 785).

See several paragraphs in "A Selected Public Health Bibliography" (pp. 792-794).

"Health Conservation Contests," (pp. 795-796) lists the 1937 winners.

"Health Education" is a subdivision under "Positions Wanted" (p. 799).

Note "Physical Education Associations Merge" (p. 801).

Why Not Use Colored Paper?—

This question is posed in "Advantages of Colored Paper," by H. Falls, in *Direct Advertising*, Boston, Mass.

"Why not write or print your message on a rich, warm, appealing shade that will attract women, instead of trying to tell your story on prosaic white paper which is in itself cold, commonplace, and impersonal?"

There is no doubt that color has a very definite influence on people. Instead of trying to get all the color into your advertising message with the use of colored inks, let the paper itself do part of the job. . . .

Why the Addresses?—So far as is practicable we give addresses from which originate whatever is mentioned in this department of the *Journal*.

This is done to facilitate correspondence direct from any interested reader. When we know the cost it is indicated.

When you send the editor a report, a pamphlet, or anything else, you would reduce the wear and tear by stating that you have some extra copies if health workers ask for them (or that you have no extra copies). If there is a price, please tell us. If 3 cents postage, or 5 cents, or more should accompany the request, please say so.

The editor does not supply the material mentioned in these pages.

"We Don't Have Time"—To prepare good health education material. That is the situation of hundreds of over-busy health officers.

One way out is to make use of what some one else has prepared.

We are delighted to see in bulletins good material quoted from other sources. And here come two examples of other uses made of material appearing in *Health News*, New York State Dept. of Health, as reported July 26, 1937:

Two city health officers, Dr. D. V. O'Leary, of Albany, and Dr. H. J. Shelley, of Middletown, recently made effective use of *Health News* items by having reprints made and distributed locally.

Dr. O'Leary distributed to several hundred local restaurants and other public eating places reprints of the "'Doctor Jones' says—" item of June 14 in which "Doctor Jones" told of seeing a restaurant worker "lick off" her fingers before and after handling food and commented on the dangers involved in this practice.

Dr. Shelley reprinted in parallel columns two items from the issue of June 28: one referring to an outbreak of scarlet fever traced to raw milk which was being sold without a permit; the other, to an award of damages against a milk dealer and producer in connection with a case of undulant fever in which the infection apparently was conveyed through milk. Dr. Shelley distributed the reprints to local milk dealers and producers.

Our disappointment is that Dr. O'Leary and Dr. Shelley did not send us samples long ago.

When the Scientist Is a Writer—Under "Publications" in the 1937 annual report of the Commonwealth Fund (41 E. 57th St., New York, N. Y.) is this paragraph:

Scientific writing in the United States is not distinguished for simplicity or grace, and much of the work in which the Fund is interested has been done in fields where concepts are still shadowy and terminology undisciplined. Moreover clarity means one thing to the scientific reader—who asks only an orderly sequence of declarative sentences built from a precise and highly specialized vocabulary—and another to the layman, who deplores "jargon," responds to simple prose rhythms, and usually needs analogy and metaphor as a bridge to unfamiliar ideas. Since the Fund serves now one audience, now another, and deals often with technical experts who are inexperienced in authorship, it requires care and flexibility in editing to make sure that each publication is in the form which will make it most useful.

The report calls attention to an important aspect of foundation publication activities:

Many of its publications fulfil their aim with sales which are numerically insignificant but which reach key people who make effective use of the books they buy . . .

On the other hand a foundation, seeking educational rather than cash returns, is in position to issue publications of value which might not interest a commercial publisher, and sometimes the results are surprising. When *The Problem Child in School* was just off the press, in 1925, a reader for a commercial publishing house estimated that in the trade total sales of 300 might be expected for it. The Fund has sold to date more than 17,000 copies. This happens rarely. But on many occasions in the last ten years there has been evidence that the books published by the Fund have been inherently useful and actually used.

"One Third of a Nation"—Under this title the WPA Federal Theater in New York City presents another "edition" of its "Living Newspaper." According to *Cue*:

"This is the biggest and most thorough of the Federal Theater's lantern slide and lecture investigations of various phases of the

nation's industry, habits, and practices. It takes the history of the housing problem in New York City for its theme, and traces it from the old colonial land grant days to the nirvana of Federal housing."

"It is a vigorous, well written, and emphatic platform-play true in every detail and with an enormous impact . . .

"It is a little shocking to be reminded that houses still exist where the law calls for only one water tap and one toilet per floor, and where central heating is one of the major mysteries. The play is a monument of ingenuity in staging, research, and in assembling, and editing, the latter done by the increasingly skillful Arthur Arent . . ."

"As a matter of fact, there is not much acting in the usual sense. In those scenes depicting the cholera plagues and in other vignettes of human misery, some neat little characterizations were accomplished briefly and to the point . . ."

"The work is hereby earnestly recommended, not only to social workers and

those interested in a further government participation in low cost housing, but to students of stage mechanics, scene designers, and people generally interested in the theatre . . ."

WANTED

A request from Hedurg B. Poehler, instructor in nutrition, Health Dept., Milwaukee, Wis., is a reminder of how little nutrition material has come in from all the health agencies of the country. Please reply direct to this inquiry:

"I would like to collect nutritional material for an exhibit at the convention of the American Dietetic Association to be held in Milwaukee this fall. Can you tell me which public health organizations, local and state boards of health, have exceptionally good pamphlets, posters, devices, etc., for teaching nutrition?"

BOOKS AND REPORTS

Manual for Water Works Operators—*Prepared by the Manual Committee, Texas Water Works Short School. Edited by E. W. Steel. Austin, Tex.: Texas State Department of Health, 1938. 278 pp. Price, \$2.00.*

In 1933 the Texas Water Works Short School for water works operators and superintendents took a forward step in emphasizing the importance of employing trained personnel in the operation of public water supplies by initiating a system of voluntary licensing of water works personnel.

Three grades of licenses are issued, based on factors that reflect the experience, training qualifications, and ability of the applicant.

Since written examinations are required in qualifying for the various grades of licenses, it seemed desirable to provide the applicants with reference material containing the basic information necessary in preparation for the examination. While the manual has been prepared to meet this especial need in Texas, it has equal value for any water works superintendent or operator who desires a compact review of the essentials of water treatment methods.

Prepared especially for in-service training of water department personnel, the manual secures brevity by the elimination of factual data that can reasonably be expected to be the common knowledge of all well informed operators. Through the use of references placed at chapter endings, supplemented by an appendix listing useful publications; the reader is stimulated to extend his technical reading in the water works field.

The manual will be a desirable addi-

tion to the library of a water works department, where it will lend encouragement to the operator who wishes to improve his technical qualifications by in-service training.

The public health administrator will be interested in the emphasis that the publication of this manual gives to the need for employing water works personnel with special training, who are qualified to assume the responsibility for the production of safe potable water for public use. EARNEST BOYCE

A Textbook of Hematology—*By William Magner, M.D., D.P.H. Philadelphia: Blakiston, 1938. 395 pp. Price, \$4.50.*

This excellent work merits a high degree of popularity among students, technicians, and practitioners of medicine. After careful study of its style, its contents, and the arrangement of its material, such a statement can be made without qualification. There were already so many good and dependable texts on hematology in our libraries the publishers must have recognized well its fine qualities before they agreed to undertake its manufacture.

The diction is clear and direct like that used by an experienced teacher. No words are wasted in discussions of controversies; the point of view of the proponent of each theory is explained briefly; at the end a single sentence places the entire matter where it seems to belong. Two instances may be noted to illustrate this method. With regard to the origin of the monocyte, various theories are credited to the proper individuals, then: "It would appear that the weight of evidence is in favor

of the view that monocytes arise from reticular cells, chiefly in the spleen and connective tissues." The differential enumeration of the granulocytes as initiated by Arneith and as modified and changed by Schilling, Booke, and Ponder, and others is explained briefly but clearly. The section ends with this statement: "The experienced hematologist will find that the more familiar he becomes with Schilling's theory and method, the more will he be attracted to the hemogram as a method of analyzing the blood picture."

The first part of the book deals with the blood and its various elements in health and in disease; a chapter is devoted to laboratory methods; then the anemias and finally the leukemias are discussed—briefly but satisfactorily. In the excellent bibliography and the carefully prepared index one finds no mention of the Niemann-Pick nor of Gaucher; considering the rarity, and difficulty in diagnosis of the conditions associated with these names, their omission is not serious.

A. P. HITCHENS

The Psychology of the Unadjusted School Child—By John J. B. Morgan (rev. ed.). New York: Macmillan, 1937. 339 pp. Price, \$2.25.

This revision of Dr. Morgan's application of mental hygiene to the understanding of the school child (at home as well as at school) is characterized by the directness and clarity, as well as by the authenticity, which marked the original edition (1924). Since 1925, the author has studied more than 2,500 children in the Psychological Clinic at Northwestern University, and his understanding and precise description of children's problems have been enriched by this experience.

"The majority of queer people whom we encounter did not become that way suddenly, . . ." says the author in his opening paragraph. "They started

early in life, often in infancy or childhood, and progressed by almost imperceptible degrees into the confirmed eccentricities that we now see." The queerness and eccentricities of adults, and even "the more extreme peculiarities that distinguish some types of mental disorder," may often be prevented if the maladjustments developing in the child are corrected. To every child, if he is to grow into a mentally healthy adult, there must be given opportunity for the joy of achievement and the satisfaction which comes from solving life's problems, himself. These, the author believes, will enable the child, as he grows up, to meet difficulties easily—even gladly.

The book is an excellent practical guide to teachers and parents.

FREDERICK W. BROWN

The Compleat Pediatrician: Practical, Diagnostic, Therapeutic and Preventive Pediatrics—By Wilbur C. Davidson, M.D. (2nd, rewritten ed.) Durham, N. C.: Duke University Press, 1938. 250 pp. Price, \$3.75.

This is a valuable compendium of pediatric materials, encyclopedic in nature, which has been prepared as a ready reference for practitioners of medicine especially interested in pediatrics. Essential information gleaned from recent pediatric literature finds a place in this unique volume. It is arranged in convenient, concise form so that any of the diseases of infancy and childhood may be traced easily as to symptoms and signs, differential diagnosis, and treatment. A very helpful chapter is included on laboratory and other procedures frequently used in pediatrics. The preventive aspects of modern pediatrics are stressed especially in the chapters dealing with nutritional requirements, gastrointestinal and circulatory diseases, metabolic and glandular groups. The extensive bibliography accompanying the book and the detailed

index add greatly to its value as a reference volume.

RICHARD A. BOLT

Diet and High Blood Pressure—
By Dr. I. Harris. Toronto, Ont., Canada: Longmans Green, 1937. 196 pp. Price, \$3.50.

This is a readable book written "for the normal individual, and not for people suffering from high blood pressure." It is based on research done under the direction of the author, on the problem of high blood pressure. It has led him to feel sure that by correct dieting the life of those suffering from high blood pressure can be prolonged. He is emphatic on prevention, and holds that no drugs will ever cure "heart disease." He says, "We put our faith in miracles, in bottles of medicine, in fashionable spas. Believe me, they are false gods; they cannot help us. There is only one way to good health and longevity—obey strictly the laws of living." He warns against gluttony, calling attention to the fact that in the past food had a different meaning than at the present, owing to the difficulty of obtaining it. "In those days a feast performed a vital function. . . . The ritual still remains. Communal feeding is apparently still the only way to mark an auspicious occasion or to do honour to an individual. . . . Public feeding in modern times is an orgy of gross over-indulgence. To gorge food and drink until our senses are benumbed is surely a crude form of sensuality. . . . Our banquets have the broad features of worship of sensuality."

While some of the author's views will be considered extreme by many, in general his teaching is sound. "The golden rule in eating is moderation and variety. There is hardly any type of food or drink which can do harm as long as one lives up to this maxim. . . . As long as one is moderate there is

very little that man cannot eat and drink."

The book ends with an appendix of 53 pages giving a number of diets, food values, and excellent recipes for preparing the foods advised. The book is easily written and may well be studied by a great variety of readers.

MAZÛCK P. RAVENEL

Safe Living—*By C. W. Hippler and Helen Burr Durfee. New York: Sanborn, 1937. 188 pp. Price, \$.80.*

It is amazing how many safety factors exist in the environment in which children of school age live, for this is a book primarily for children. The text is a record of plausibly real experiences by the children themselves.

The recounting is largely in dialogue, partly in description. The teacher's participation is behind the scenes. It is the children who develop the problems and find the solutions. There is a ring of earnest sincerity in the text as if the authors were impelled by deep conviction.

The fields for safety the book covers are school, going to and from school, home, neighborhood, highway, farm, and vacation. The chapter on Safety and Health reviews briefly some of the general health practices particularly applicable to children. An excellent book.

W. W. PETER

Let's Help the Doctor—*By Margaret O'Donovan Rossa, R.N. New York: The Devin-Adair Company, 1937. 141 pp. Price, \$1.50.*

This book had two origins. The overwhelming cost of hospital care and nurses for the average one-salaried family. The lack of information among intelligent mothers about what to do for the sick at home.

Out of her own experience and observation as a private duty nurse the author assembled this compendium. It attempts to give instruction of a kind

in many directions so that mothers may know what to do and what not to do to help the doctor in cases of sickness which can be cared for in the home.

W. W. PETER

Father's Doing Nicely—*The Expectant Father's Handbook*—By David Victor. Foreword by George W. Kosmak, M.D., drawings by Tom Torre Bevans. New York: Bobbs Merrill. 170 pp. Price, \$1.50.

The expectant father has been the butt of many good natured jokes. Classes for expectant fathers have been formed in few places. Obstetricians and nurses have had to deal with "paternity pains" as best they could. All this calls for a plain statement of the facts illustrated with caricature and humor which the average man can well understand. This delightful book fills such a need. From the outside cover to the last page it affords an antidote to the fears and forebodings of "the forgotten man of procreation." Intermingled with the humor and drawings there is a serious strain which emphasizes the essential acts in the drama of childbirth in such a manner that it will pass through the mails without censorship. As Dr. Kosmak points out in the foreword, "in recommending the book for prospective fathers, attention can be directed to the fact that it should prove of equal value to their wives."

RICHARD A. BOLT

The Sanitary Inspector's Handbook: A Manual for Sanitary Inspectors and Other Executive Public Health Officers—By Henry H. Clay. (3rd ed.) London: Lewis, 1937. 480 pp., 95 ill. Price, \$5.00.

The demand for the second edition (1936) of this admirable work made it possible to publish this edition synchronously with the coming into operation of the British Public Health Act, 1936. References to new Acts,

Regulations, and Byelaws have been made in considerable detail because of their importance to all public health administrators and sanitary inspectors of Great Britain. Such thorough revision as has seemed necessary has resulted in the third edition being nearly 100 pages larger than the first.

While this volume is intended specifically to be a guide and reference text for sanitary inspectors working under the English regulations, and therefore invaluable to them, it is truly a mine of information for all others as well who are concerned with the public health. The arrangement of the material which constitutes nearly all of the 31 chapters is in keeping with other rare qualities of the book. First there is explanatory matter, then are quoted the legal provisions which pertain to the subject, and the chapter ends with an exhaustive discussion of accessory information intended to give the inspector an adequate background for his work.

The final chapter contains "Useful Memoranda and Glossary of Building Terms." This includes data of all varieties from the value of "pi" to the definition of "Brick Nogging."

It has not been possible to find in the excellent index any reference to the sanitation of public eating and drinking establishments. Supervision of the cleansing of tableware and beer glasses is probably not a function of the sanitary inspector.

The book is admirable in every way and its usefulness is not by any means localized by its having been written around British Acts, Regulations and Byelaws.

A. P. HITCHENS

Programs for Local Tuberculosis Associations — Administrative Series No. 4—Prepared by Murray A. Auerbach. New York: National Tuberculosis Association, 1937. 67 pp. Price, \$5.50.

As a chart for executives in charge of local tuberculosis associations, it would be hard to excel this monograph. It is a scholarly and thorough piece of work that demonstrates the wide knowledge of programs that have been carried on and their successes and failures, and the fundamentals of an intelligent approach to tuberculosis work. Not only that, but the author shows that he has had enough experience to recognize the value of good community organization and to know how to get it.

From the point of view of those interested in community health programs extending beyond the field of tuberculosis, one is impressed by the fact that there needs to be the closest possible coördination of tuberculosis programs with those of other agencies in the health field. Their work touches at many points. Many of the technics and programs suggested will be useful to any health executive. They should be helpful to the official health commissioner in knowing how to use community resources and the most effective means of coöperating with the local tuberculosis association.

While the tuberculosis problem remains an outstanding one in spite of the progress that has been made, and a big job still lies ahead, nevertheless its very successes make it clear that the time will come when the problem will be sufficiently under control that tuberculosis organizations will naturally develop into community health organizations in which their possibilities will be practically unlimited.

For the tuberculosis secretary comparatively new to his work, Mr. Auerbach's treatise will be a boon. For the experienced executive, these ideas so clearly set forth, will prove decidedly helpful. He may well use these programs even though they do not presume to be complete, to check on his own activities. As a concise, practical

presentation, this little pamphlet sets a high mark. BLEECKER MARQUETTE

Journal of Milk Technology—*Vol. I, No. 1, October, 1937, to Vol. I, No. 3, March, 1938. Official publication of the International Association of Milk Sanitarians, 17-19 Day Street, Orange, N. J. Subscription price, \$5.00.*

The familiar blue covered report issued yearly by the International Association of Dairy and Milk Inspectors has undergone a metamorphosis after the publication of the *25th Annual Report* of this Association. The proceedings of this Association, which changed its name in 1936 to the International Association of Milk Sanitarians, are now to appear in the form of a blue covered bi-monthly journal known as the *Journal of Milk Technology*.

Three numbers of this journal have already appeared and are sufficient to show that this method of publication is an improvement on the older method as it not only permits the printing of the papers presented at the annual meeting of the association but also allows the insertion of a certain amount of new and current material. Papers of particular importance to dairy and milk inspectors are also being abstracted, making the publication one of very real value to all men interested in dairy and milk inspection work. As the journal is the official publication of the association, all members of the association receive it without any increase in the membership dues of \$5 a year.

ROBERT S. BREED

Clinical Psychology: A Handbook of Children's Behavior Problems—*By C. M. Louttit. New York: Harper, 1936. 695 pp. Price, \$3.50.*

If one were to evaluate this book entirely on the basis of its more than 800 summaries of the most recent research in the field of clinical psy-

chology and the 60 other extensive quotations from case histories of behavior problems and their treatment, it would be described as a well organized and carefully documented reference book. The author's clear interpretation of his material and the practical applications of it give it added value as a "textbook for students of clinical psychology."

Its contents may be briefly indicated:

Part I—Methods, includes an introductory chapter and two chapters on Diagnostic Methods, devoted to Anamnesis and Examination and to Psychometrics, respectively.

Part II—Problems Correlated with Abilities, deals with the following topics, to each of which a chapter is given: Mental Deficiency or Feeble-Mindedness; School Retardation; Specific Disabilities in School Subjects; and Superiority.

Part III—Primary Behavior Problems, contains 6 chapters covering the following subjects: Behavior Problems: Introduction; Conduct Problems; Juvenile Delinquency; Speech Defects; Personality Problems; Psychoneuroses and Psychoses.

Part IV—Problems Correlated with Organic Disabilities is divided into two chapters, the first dealing with Sensory Defects and the second with Neurological and Physical Disabilities.

A list of references and a good index complete the volume.

In a foreword L. T. Meiks, M.D., emphasizes the unique opportunities of the family physician and the pediatrician for observation and intimate knowledge of the family background of children under their care and the recognition "of many of these behavior disorders in their incipience, before the untrained associates of the child realize that the reactions are in any way undesirable. An enlightened medical profession," he says, "can do much to prevent the development of these disorders and to handle them in the proper fashion once they have appeared." Both Dr. Meiks and the author recognize the need for the specialized technics of the trained psychiatrist and clinical psychologist in solving many behavior problems. Running throughout the book

is the refrain, "Treat the child as an integrated whole."

The book should serve its purpose well, whether its reader be the embryo psychoclinician, to whom it is addressed, the medical student, or the physician or school administrator seeking to keep abreast of the most recent work in the field of clinical psychology.

FREDERICK W. BROWN

More of My Life—By Andrea Majocchi. New York: Knight Publishers, 1938. 313 pp. Price, \$2.50.

All who read *Life and Death* will welcome this addition to the autobiography of Italy's famous surgeon. The author speaks of these new stories as "Pages from my life . . ." "notes torn from a surgeon's diary," yet they have, as he says, a definite relationship to one another although apparently little connected. To a certain extent it is a biographical sketch of a great friend and senior surgeon, Dr. Franco Forti.

Biographies, even of the humblest people, if they are sincere, carry much of interest. When we have the story of a man who has come into contact with life in so many varied forms as the author of this book, it cannot but be of intense interest. Some of the chapters have been dedicated to three persons, an unknown patient, a nun, and a priest, who had been deeply moved by reading *Life and Death*. We have no hesitation in picking out these chapters as easily the best in the book, The Sacrifice, The Hymn to the Sun, Mass at the Front, and Sunset. To these we would add, Human Depths.

It seems to have become the fashion for doctors to write autobiographies. Among those which have appeared, this stands easily among those at the top. It is the story of a man who has worked hard, studied both books and men, has loved his kind and devoted his life to their betterment. Above all, it is simple

and sincere. It can be recommended without reservation.

The book is beautifully printed and gotten up. It is a pity that the translator did not consult a doctor, which would have avoided several errors which jar on the professional man.

MAZÏCK P. RAVENEL

Step by Step in Sex Education—
By Edith Hale Swift, M.D. New York: Macmillan, 1938. 207 pp. Price, \$2.00.

This is a unique presentation of sex education material arranged in dialogue form between parents and a boy and girl in the normal relations of family life. It proceeds step by step as the children advance in age to give them a scientific nomenclature of sex anatomy and physiology, at the same time revealing to each child the personal and social implications of sex. It is written primarily for parents who are at a loss to know how to approach the subject when confronted by the curiosity and perplexing questions which modern children present. It is clothed in everyday conversational style and is clear and concise without a trace of morbidity, although the author does not stop at introducing the most intimate situations in sex relations. The only part of the book which might arouse controversy is that dealing with contraception, which is confined to a few pages at the end.

RICHARD A. BOLT

Fluorine Intoxication—A Clinical-Hygienic Study, with a review of the literature and some experimental investigation—*By Kaj Roholm. Copenhagen: Nyt Nordisk Forlag—London: H. K. Lewis and Co. Ltd., 1937. 364 pp.*

In a succinct review, it is impossible to do adequate justice to what is probably the outstanding contribution to the literature of fluorine. The thorough

manner in which the author deals with the subject expresses itself in a monograph which includes 57 tables, 96 figures, and a bibliography of 893 references.

Although primarily begun as an industrial hygiene study, the author has encompassed the whole field of fluorosis in a manner that makes the book one of equal interest to those in other branches of medicine, especially pediatricians, orthopedists, and radiologists, as well as epidemiologists, dentists, biochemists, veterinarians, and agriculturists.

The discussion of the prevention of fluorine intoxication embraces the whole group of fluorine compounds found in industry. The author states (p. 310) that "it would be desirable to forbid the employment of males under 18 years and females as a whole, on work with fluorine compounds which give off dust or vapour." The necessity for control of all sources where fluoric dust or vapor is generated, is emphasized in detail, not only with respect to the workers but to that area surrounding the factory that might become contaminated by volatile fluorine compounds.

Although numerous experiments in induced experimental fluorosis have shown considerable storage of fluorine in the bones with a resultant development of defective osseous structure, Roholm demonstrates that comparable conditions are not uncommon among cryolite workers.

In a chapter entitled "Post Mortem Examinations of Two Cryolite Workers," the author records (p. 184): "After *Skeletonizing*, the bones present marked changes. All are of a chalky-white color, the surface is irregular and the weight considerably increased." Calcification of the ligamentous attachments was commonly observed. The fluorine content of the costal bones was 9.9 and 11.2 mg. per gm. of bone ash respectively whereas about 0.5–2.1 mg. of fluorine per gm. of bone ash is re-

ported for 11 normal human costal bone samples. These two workers had been exposed for 9 and 24 years respectively to cryolite ($\text{Na}_3 \text{Al F}_6$) dust with a calculated fluorine intake daily of about 0.20–0.35 mg. of fluorine per kg. of body weight.

The author also observes that among 5 children "born of women who either worked at the cryolite factory before or during pregnancy or started to work soon after the birth, 3 showed a mottled enamel condition of the teeth" years later when the permanent teeth erupted.

From a diagnostic viewpoint, Roholm divides chronic fluorosis into three different stages.

1. The dental anomaly known in man as mottled enamel and in the herbivora as darmous or gaddur

2. Osteosclerosis, an occupational disease among cryolite workers and possibly other workers exposed to relative large amounts of fluoride

3. An osteomalacia-like disease endemic among herbivora in the environs of certain factories in Europe

The dosage that can produce the various forms of this chronic intoxication is uncertain according to the author, but seems to rise from (1) to (3).

For those interested in any of the various phases of fluorine intoxication, this book is especially recommended.

H. TRENDLEY DEAN

The Subnormal Mind—By Cyril Burt, M.A., D.Sc. (Oxon.). (2nd ed.) New York: Oxford University Press, 1937. 372 pp. Price, \$5.00.

This volume is an assemblage of the third series of Heath Clark Lectures, delivered at The London School of Hygiene and Tropical Medicine in 1933, revised for publication. That a second edition was called for in a short time—the first appeared in 1935—is practical evidence of the favor which the book has received.

The opening chapter is devoted to the normal mind, hence the author proceeds to his presentation of the mentally deficient, the dull or backward, the delinquent, and the asthenic and the sthenic neuroses.

The American reader will be interested in the discussion of such English legislation as the Mental Deficiency Act of 1927. The author has brought together the findings of many English studies, including his own, and from these he presents statistical evidence as to prevalence and causes of the conditions dealt with. From these facts he draws his conclusions in what appears to be a reasonable and fair manner. The relationship between such environmental conditions as lead to lack of rest and to retardation in school is brought out forcibly.

Regarding the delinquent, the conclusion is: "About the value of preventive psychology or medicine in dealing with the adult criminal, I am, indeed, pessimistic; over the treatment of the juvenile offender, I am almost always hopeful, and the younger the case, the higher my hopes."

The book is well printed, the style is good, and the material well organized. There is no undue repetition, and the author is not dogmatic in his own point of view. Throughout, there runs a pleasant humanistic touch which gives conviction regarding the author's opinion. This volume is a worth while addition to the library of any worker in the broad field of child welfare.

GRANT FLEMING

The Collapse Therapy of Pulmonary Tuberculosis — By John Alexander, M.D., F.A.C.S. Springfield, Ill.: Thomas, 1937. 705 pp. Price, \$15.00.

The subject of collapse therapy of tuberculosis is covered in detail in this excellent book. Chapters one and two are devoted to the perspective of col-

lapse therapy in tuberculosis and the evolution of surgical therapy. Following are sections on physiological principles and pathology of pulmonary collapse by Dr. Max Pinner. Two chapters on pneumothorax are contributed by Dr. John Blair Barnwell and a chapter on oleothorax by Dr. Kirby Smith Howlett, Jr.

The author has admirably fulfilled his purpose, as stated in the preface, of writing a book for both surgeon and internist. Based on wide clinical experience, the indications and contraindications for the various operations that may be performed in the treatment of pulmonary tuberculosis are discussed. The section on "choice of operation" is of equal interest to all phthisiologists who are faced with the problem of determining the proper time for surgical intervention.

The technic, preoperative and post-operative management, as well as vari-

ous complications that may arise in each surgical procedure are described in detail. Discussions of operative technic are supplemented by excellent illustrations.

Exceptions may be taken to certain details and particularly the choice of anesthesia for thoracoplasty. Such criticisms, however, are of minor importance, as the work supplies, with authoritative clarity and in a practical and detailed manner, valuable information concerning all phases of the collapse therapy in tuberculosis.

The material is well organized and indexed, and extensive references to the literature are given. This work is recommended to all who are interested in the subject of tuberculosis.

The book is beautifully printed and the make-up fine. It is a typical example of the excellent products which come from the house of the printer.

BRIAN BLADES

BOOKS RECEIVED

PARASITOLOGY. With Special Reference to Man and Domesticated Animals. By Robert Hegner, Francis M. Root, Donald L. Augustine and Clay G. Huff. New York: D. Appleton-Century, 1938. 812 pp. Price, \$7.00.

MATERNAL CARE COMPLICATIONS. Dr. F. L. Adair, Editor. Chicago: University of Chicago Press, 1938. 95 pp. Price, \$1.00.

A GENERAL TEXTBOOK OF NURSING. By Evelyn C. Pearce. New York: Dutton, 1938. 888 pp. Price, \$3.75.

INSULIN. Its Production, Purification and Physiological Action. By Douglas W. Hill and Frederick O. Howitt. New York: Chemical Publishing Co., 1936. 219 pp. Price, \$5.00.

SOUTH ITALIAN FOLKWAYS IN EUROPE AND AMERICA. A Handbook for Social Workers. New Haven: Yale University Press, 1938. 216 pp. Price, \$2.50.

PHYSICAL AND HEALTH EDUCATION. Principles and Procedures. By Helen Norman Smith and Helen Leslie Coopes. New York: American Book Co., 1938. 323 pp. Price, \$2.25.

INTRODUCTION TO BACTERIOLOGICAL CHEM-

ISTRY. C. G. Anderson. Baltimore: Wood, 1938. 278 pp. Price, \$4.00.

SWIMMING AND DIVING. By American Red Cross. Philadelphia: Blakiston, 1938. 271 pp. Price, \$.60.

SALARIES IN MEDICAL SOCIAL WORK IN 1937. By Ralph G. Hurlin. New York: Russell Sage, 1938. 34 pp. Price, \$.20.

REPORT OF THE HOSPITAL SURVEY FOR NEW YORK. By Arthur W. Jones and Francisca K. Thomas. Vol. III. New York: United Hospital Fund, 1938. 571 pp. Price, \$2.00.

MACLEOD'S PHYSIOLOGY IN MODERN MEDICINE. Edited by Philip Bard. 8th ed. St. Louis: Mosby, 1938. 1051 pp. Price, \$8.50.

TECHNICS FOR THE BACTERIOLOGICAL EXAMINATION OF DRINKING WATER. Fifteen methods currently in use. Health Officers' News Digest, Public Health Committee of the Cup and Container Institute, 30 Rockefeller Plaza, New York City, 1938. 10 pp. Mimeographed. Free upon application.

HEALTH GUIDES AND GUARDS. By Francis P. Wall and Louis D. Zeidberg. New York: Prentice-Hall, 1938. 380 pp. Price, \$1.40.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Food for Thought—Complacent sanitarians will be shocked to learn that smallpox has been increasing since 1934. In 1937, more than 11,000 cases occurred, and during the first 20 weeks of 1938 the incidence was twice as high as during the same time last year. With the exception of India, and one or two other benighted countries, the grand old U. S. enjoys the highest smallpox rates. The problem is confined generally to the central and western states.

ANON. Prevalence of Communicable Diseases in the United States. *Pub. Health Rep.* 53, 23:935 (June 10), 1938.

How May Nursing Services Be Measured?—Total home and school visits and clinic attendances is an unsatisfactory measure which, when vigorously applied, discourages the nurse from giving the health services her visits are intended to provide. Length of visit in the home is suggestive only in the lower brackets. Something should be done about developing valid indices of accomplishment rather than putting on heat through widespread use of quantitative measures.

BEAN, H. Number and Length of Nursing Visits as Indices of Nursing Services. *Pub. Health Rep.* 53, 22:913 (June 3), 1938.

Midwives in Great Britain—It is to be regretted that many American sanitarians will not have the opportunity to see this series of papers on British midwifery services, if only to open their eyes to the fact that in some European countries the midwife is a recognized public health servant on a par with the home visitor and the

technician. Of course, we do things better over here: with certain outstanding exceptions, we hide our collective head in the sand so we may blissfully ignore the whole problem.

BERKELEY, C., *et al.* The Operation of the Midwives Act, 1936. *Pub. Health.* 51, 9:257 (June), 1938.

Sound Health for All—Forcibly reminding us that a large part of public health activities are concentrated on the care of the known sick rather than devoted to the improvement of the apparently well, the future program had better be pointed to improving housing, better application of the principles of nutrition, development of mental hygiene, and the encouragement of physical fitness, suggests the author.

BOUDREAU, F. G. Family Health Goal of Public Health. *Pub. Health Nurs.* 30, 6:346 (June), 1938.

Pollution Movement from Latrines—Chemicals placed in a typical privy vault can be recovered over 300 feet away, but fecal organisms were limited to a 10 foot dispersion. In pervious soils the colon organisms did not penetrate more than a foot below a dry latrine, and only about 6 feet from a wet latrine. Probably there are many more findings of importance to sanitarians in the 67 pages in three papers devoted to this subject.

CALDWELL, E. L. Pollution Flow from a Pit Latrine When Permeable Soils of Considerable Depth Exist Below the Pit. *et seq.* *J. Infect. Dis.* 62, 3:225 (May-June), 1938.

Where Knowledge Is the First Need—Detroit's negro population tripled in 17 years. Essentially a rural people, city environment raises havoc

with them. The infant death rate was 5 times that of the white population. Health education was and is badly needed. How Detroit meets the need is interestingly told.

CONNOLLY, M. P. Helping the Negro to Help Himself. *Health Officer*. 3, 1-2:19 (May-June), 1938.

Poliomyelitis Epidemiology — Prevalence of poliomyelitis since 1916 is considered, and distribution of the disease by counties during the last 5 year period is reported. Although the disease is country-wide, it is extremely irregular in its appearance; in some outbreaks only a few counties are involved, in others whole regions. Case and fatality rates showed great variation from year to year and place to place. One conclusion is that we should make more epidemiologic studies as well as expand laboratory research.

DAUER, C. C. Studies on the Epidemiology of Poliomyelitis. *Pub. Health Rep.* 53, 25:1003 (June 24), 1938.

Common Sense Advice about Health Education—Health education will be effective to the extent that all departmental staff members are giving the same advice, that the medical profession agrees with the advice, that health workers practise what they preach, and talk in terms intelligible to the public, that they appeal to basic wants, and avoid giving advice which the recipient may know or think not to be true in his case.

DERRYBERRY, M. Taking the Public with You. *Health Officer*. 2, 12:615 (Apr.), 1938.

Mumps — Encephalitis following mumps is not so unusual as it was thought to be and may occur when the symptoms are mild.

FINKELSTEIN, H. Meningo-Encephalitis in Mumps. *J.A.M.A.* 111, 1:17 (July 2), 1938.

Tick Fever—Where and when spotted fever infections have been re-

ported over a period of 5 years. The Southeast and the Rocky Mountain states have had most cases.

HAMPTON, B. C., and EUBANK, H. G. Rocky Mountain Spotted Fever. *Pub. Health Rep.* 53, 24:961 (June 17), 1938.

Fats, Dyes, and Mystery—What every young lady health worker should know about soap, powders, creams, lotions, sunburn preventives, rouge, lipstick, dyes, nail polishes, hair tonics, deodorants, depilatories, etc., etc. Men will be interested, too. Health educators will wish for some way to measure the buying habits of lady sanitarians before and after taking this excellent advice.

HAZEN, H. H. Cosmetics. *Am. J. Nurs.* 38, 7:791 (July), 1938.

Counting Missing Teeth—Tooth mortality rates in grade school children in Hagerstown were determined by counting extracted permanent teeth. Analysis of the data is concerned with: mortality by kinds of teeth, in relation to fillings, and numbers of missing teeth per child.

KNUTSON, J. W. Studies on Dental Caries. *Pub. Health Rep.* 53, 25:1021 (June 24), 1938.

Some Working Hypotheses on Cancer—This we know: we can induce certain cancers at will, and prevent their appearance; but there are many well defined questions to be answered which may turn about two conceptions (1) irreversible metabolic changes leading to growth processes, and (2) interaction of growth stimulating factors and viruses. The paper should be read by all.

LOEB, L. The Causes of Cancer. *Sci. Month.*, July, 1938, p. 51.

About Tuberculosis—Just about the clearest discussion of tuberculosis infection and resistance that has been presented to health workers. Instead of childhood and adult types of tuber-

culosis infection, the authors urge the use of primary infection and reinfection tuberculosis. Reinfection occurs when the forces of defense are down, or when the second invasion is overwhelming. Since 1850 the destructiveness of tuberculosis has waned, though it is still the chief cause of death in young and middle-aged adults, and hence our most important public health foe.

MARGULIS, A. E., and PINNER, M. Pathogenesis of Tuberculosis. *Pub. Health Nurs.* 30, 7:412 (July), 1938.

British Health Nurses and Ours—Comparing public health nursing in Great Britain and America, it is discovered that the major problems—insufficient nurses, inadequate educational facilities, unsatisfactory living conditions and salaries—are pretty much the same in both countries.

McIVER, P. The Nurse's Contribution to the British Public Health Program. *Health Officer.* 3, 1-2:15 (May-June), 1938.

Variable Streptococci—Confirmation of the theory that when streptococcus cultures are aged under unfavorable conditions, small viable forms are produced which are capable of passing filters. Under suitable cultural conditions, they may assume visible forms. All this is very disturbing to us older sanitarians who learned our bacteriology when a streptococcus could be depended upon to remain a predictable germ.

NICHOLLS, E. E. A Study of the Organisms Recovered from Filtrates of Cultures of Hemolytic Streptococci. *J. Infect. Dis.* 62, 3:300 (May-June), 1938.

Canadian Milk Supplies—This series of papers covers about everything in its field: milk-borne diseases, laboratory methods, field supervision, pasteurization and tests for completeness, ending with the status of the milk supply in all Canadian municipalities.

PRICE, R. M. Bovine Tuberculosis in Children (and 15 other papers). *Canad. Pub. Health J.* 29, 6:251 (June), 1938.

Call to Arms against Cancer—Proposing a nation-wide cancer control scheme in which the state and federal governments might participate, the author points out that of the 420,000 annual deaths from cancer, from 25 to 30 per cent might be prevented by a thorough-going application of known control measures.

SCHERESCHEWSKY, J. W. The Prevention and Control of Cancer: A Plan for Nation-wide Organization. *Pub. Health Rep.* 53, 24:961 (June 17), 1938.

Menace of Mild Polio—Ill with poliomyelitis only 3 days, a child showed virus in the stools that persisted for 3 weeks. This suggests that mild and often unrecognized cases may be responsible for sewage pollution with the virus.

TRASK, J. D. Poliomyelitis Virus in Human Stools. *J.A.M.A.* 111, 1:6 (July 2), 1938.

ASSOCIATION NEWS

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association, the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, providing such petition is received fifteen days before the Annual Meeting." The *Chairman* of the Committee is Dr. John J. Sippy, San Joaquin Local Health District, Stockton, Calif.

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Kansas City will be elected for the three year term 1938-1941.

The Upjohn Company,
Kalamazoo, Mich.

J. L. Pomeroy, M.D.
County Health Officer,
Los Angeles, Calif.

I. C. Riggin, M.D.
State Health Commissioner,
Richmond, Va.

Grace Ross, R.N.
Department of Health,
Detroit, Mich.

Frederick W. Sabian, Ph.D.
Michigan State College,
East Lansing, Mich.

Vivien A. Van Volkenburgh, M.D.,
State Department of Health,
Albany, N. Y.

H. A. Whittaker
State Board of Health,
Minneapolis, Minn.

C.-E. A. Winslow, Dr.P.H.
Yale University,
New Haven, Conn.

C. C. Young, D.P.H.
State Department of Health Laboratory,
Lansing, Mich.

APPLICANTS FOR FELLOWSHIP

In accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Eligibility, and the Governing Council will take place between now and the time of the Kansas City Annual Meeting.

Health Officer's Section

Paul H. Brown, M.D., Dr.P.H., Health Commissioner, Stamford, Conn.

Millard C. Hanson, M.D., Dr.P.H., Director of Health, Toledo, O.

Lester C. Krotcher, M.D., Director, Local Health Administration, State Division of Public Health, Boise, Ida.

Alex M. Lesem, M.D., Health Officer, City and County of San Diego, San Diego, Calif.

Aaron Leifer, M.D., M.S.P.H., Medical Officer-in-charge Brownsville Health District, New York City Department of Health, Brooklyn, N. Y.

J. W. Roy Norton, M.D., M.P.H., Assistant Director, Division of Preventive Medicine, State Board of Health, Raleigh, N. C.

Domingo F. Ramos, M.D., D.Sc., Director of Health, Havana, Cuba

John C. Sleet, M.D., Health Commissioner, Norfolk, Va.

Kenneth H. Sutherland, M.D., Health Officer, Orange County, Santa Ana, Calif.

James O. Wails, M.D., C.P.H., Director, Nashoba Health Unit, Ayer, Mass.

Charge of District Public Health Laboratory, State Board of Health, Parsons, Kans.
John A. Toomey, M.D., Associate Pediatrician, University Hospitals, Cleveland, O.
D. Evelyn West, B.S., Chief Microbiologist, Bureau of Laboratories, State Department of Health, Hartford, Conn.

Public Health Engineering Section

Samuel D. Macready, Sanitary Officer, State Board of Health, West Palm Beach, Fla.
Thomas M. Riddick, M.S. in C.E., Consulting Chemist, New York, N. Y.

Industrial Hygiene Section

William McK. Gafafer, D.Sc., Research Associate and Senior Statistician, U. S. Public Health Service, Washington, D. C.
Leonard J. Goldwater, M.D., Sc.D., Senior Industrial Hygiene Physician, Division of Industrial Hygiene, New York State Department of Labor, New York, N. Y.
Harry F. Wilson, M.D., C.P.H., Director, Division of Industrial Hygiene, State Board of Health, Columbia, S. C.

Laboratory Section

Henry E. Cope, M.D., Associate, Owen Clinical Laboratories, Detroit, Mich.

Joseph A. Kasper, M.D., Director, Bureau of Laboratories, Department of Health, Detroit, Mich.

Raymond E. Leach, A.B., Bacteriologist in

Food and Nutrition Section

Matthew E. Highlands, S.M., Assistant Professor of Bacteriology, University of Maine, Orono, Me.
Abraham Lichterman, Ph.D., Acting Director of Foods and Drugs, Department of Health, New York, N. Y.

Ira A. Manville, M.D., Ph.D., Clinical Associate, Professor of Medicine, University of Oregon, Multnomah, Ore.

Rachael L. Reed, M.D., Director, Kansas City Dairy Council, Kansas City, Mo.

Henry T. Scott, Ph.D., Director of Research, Wisconsin Alumni Research Foundation, Madison, Wis.

Donald K. Tressler, Ph.D., Head, Chemistry Division, New York State Agricultural Experiment Station, Geneva, N. Y.

Child Hygiene Section

Jacob A. Salzmänn, D.D.S., Director, Dental Service, New York City Vocational Schools, New York, N. Y.

Harry Strusser, D.D.S., Chief, Division of Dental Service, Department of Health, New York, N. Y.

Charles C. Wilson, M.D., Director of Health and Physical Education, Public Schools, Hartford, Conn.

Public Health Education Section

H. Shirley Dwyer, D.D.S., Supervising Dentist, Department of Health, New York, N. Y.

Public Health Nursing Section

Olive M. Whitlock, B.S., Director, Division of Public Health Nursing, State Board of Health, Portland, Ore.

Epidemiology Section

William L. Aycock, M.D., Assistant Professor of Preventive Medicine and Hygiene, Harvard Medical School, Boston, Mass.

Martin R. Beyer, M.D., State Epidemiologist,

State Department of Health, Oklahoma City, Okla.

G. Howard Gowen, M.D., Ph.D., Assistant Epidemiologist, State Department of Health, Springfield, Ill.

Eschscholtzia L. Lucia, Ph.D., Assistant Professor of Biometry, University of California, San Francisco, Calif.

Henry E. Meleney, M.D., Associate Professor of Preventive Medicine and Public Health, Vanderbilt University School of Medicine, Nashville, Tenn.

Franklin H. Top, M.D., D.P.H., Medical Epidemiologist, Detroit Health Department and Herman Kiefer Hospital, Detroit, Mich.

Unaffiliated

Travis P. Burroughs, M.D., C.P.H., Secretary, State Board of Health, Concord, N. H.

Garner M. Byington, M.D., Director, Medical Relations, Department of Health, Detroit, Mich.

Frederick Eberson, M.D., Ph.D., Epidemiologist, Bureau of Communicable Diseases, Department of Health, San Francisco, Calif.

Walter H. Hartung, M.D., State Director of Health, Columbus, O.

John B. Hawley, M.S., Consulting Engineer, Fort Worth, Tex.

John O. McCall, D.D.S., Director, The Murry & Leonie Guggenheim Dental Clinic, New York, N. Y.

Harry E. Ungerleider, M.D., Assistant Medical Director, Equitable Life Assurance Society of the United States, New York, N. Y.

CLOSING DATE FOR SUBMITTING APPLICATIONS FOR FELLOWSHIP

SEPTEMBER 1 is the latest date the Committee on Eligibility can accept Fellowship applications. This date is set in order that there may be sufficient time to route them through the preliminary steps necessary before they

receive final consideration at the hands of the Governing Council during the Kansas City Annual Meeting. Eligible members who wish to apply for Fellowship are therefore urged to submit their applications in the near future.

CORRECTION

In a review of the *Report on the British Health Services, by the Health Group of PEP*, published by PEP, 16 Queen Anne's Gate, London, published on page 787 of the June issue of the JOURNAL, an error appeared due to a mistake in the original *Report* which

has been later corrected by an Erratum.

Instead of "... According to one of the tables, in 1933 and 1934 there were 59 diphtheria deaths per 1,000 boys, ages 2-5, and 55 diphtheria deaths per 1,000 girls, ages 2-5 ..." this should read "death rate per 100,000 living," not "per 1,000."

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Charles A. Arneson, M.D., 400½ Main St., Bismarck, N. D., City Health Officer
 Manuel S. Barreto, M.D., C.P.H., 113 Soublet St., Valencia, Venezuela, S. A., Health Officer
 Robert L. Cherry, M.D., C.P.H., State Dept. of Health, Kaufman, Tex., Director, Public Health District 3
 Leo F. Chess, M.D., Reed City, Mich., Health Officer
 Ramon Fernandez Marchante, M.D., Public Health Unit, Fajardo, P. R., Chief, Public Health Unit
 C. K. Heady, M.D., 26 Cherry St., Milford, Conn., Health Officer
 Willis B. Johnson, M.D., Box 1325, Rt. 4, Everett, Wash., Snohomish County Health Officer
 William W. Kelly, M.D., Bellin Bldg., Green Bay, Wis., President-Elect, State Board of Health
 Joseph T. Marshall, M.D., Gainesboro, Tenn., Assistant Director, Upper Cumberland Health District
 William C. D. McCuskey, M.D., 60-14 St., Wheeling, W. Va., Member, West Virginia Public Health Council
 William B. Nies, M.D., Court House, Fort Worth, Tex., Tarrant County Health Officer
 Arthur B. Robins, M.D., 534 E. 87 St., New York, N. Y., Supervisor of Clinics, Bureau of Tuberculosis, Department of Health
 Lloyd H. Smith, M.D., Box 418, Coulee City, Wash., Health Officer, Grant and Douglas Counties, and Grand Coulee District
 Alvin L. Stebbins, M.D., 803 N. Palafox, Pensacola, Fla., Director, Pensacola-Escambia County Health Unit
 H. E. Stroy, M.D., 107 S. Main, Osceola, Ia., Member, State Board of Health
 Roy B. Weathered, M.D., Eldorado, Kans., Butler County Health Officer

Laboratory Section

- A. P. Black, Ph.D., University of Florida, Gainesville, Fla., Professor of Agricultural Chemistry
 Josephine M. Day, Santa Maria Hospital, Santa Maria, Calif., Laboratory Technician, Santa Barbara County Health Dept.
 Melvin E. Koons, Box C, University Station, Grand Forks, N. D., Director, Public Health Laboratory

Norman C. Laffer, Ph.D., Box 4302, University Station, Tucson, Ariz., Teacher of Bacteriology, University of Arizona

Vital Statistics Section

- Margaret M. Crowe, City Hall, Kansas City, Mo., Registrar, Bureau of Vital Statistics, Health Dept.
 Rose A. Marks, 3218 Linwood Blvd., Kansas City, Mo., Statistician, Health Dept.
 Pauline V. Turner, 2680 Bancroft Way, Berkeley, Calif., Student

Public Health Engineering Section

- Raymond C. Freeman, Colerain, N. C., Sanitarian, State Board of Health
 Arthur G. Fuller, 4554 S. 3rd, Louisville, Ky., Sanitary Engineer, City Health Dept.
 Paul M. Kiel, 25 Sycamore St., Tiffin, O., State Dept. of Health (At present—Trainee at University of Michigan)
 Sigvard J. Nielsen, 25 Fordonia Bldg., Reno, Nev., Sanitary Inspector, State Board of Health
 Darwin E. Hoffert, 1214-14 Ave. N., Fargo, N. D., District Sanitation Supervisor, State Dept. of Health
 James R. Spence, Fayette, Ala., County Sanitation Officer, State Board of Health

Industrial Hygiene Section

- Hugh P. Brinton, Ph.D., 3016 Dumbarton Ave. N.W., Washington, D. C., Associate Statistician, Division of Industrial Hygiene, U. S. Public Health Service
 Clayton L. Hawkins, M.D., 2701 Welton St., Denver, Colo.
 Leroy W. La Towsky, 2506 N. 55 St., Omaha, Nebr., Student

Food and Nutrition Section

- Wallace P. Elmslie, Ph.D., Moorman Mfg. Co., Quincy, Ill., Director of Research
 Robert F. Huntley, Sealright Co., Inc., Fulton, N. Y., Technical Director, Charge of Bacteriological and Chemical Research and Control

Child Hygiene Section

- Burke C. Brewster, M.D., 467 E. Weatherford St., Fort Worth, Tex., Director of Health, Fort Worth Independent School System
 Rhoda Larsen, R.N., Mantua, Utah, Emery County Public Health Nurse

Mary W. Tobin, Duquesne University, Pittsburgh, Pa., Dean, School of Nursing

Public Health Education Section

Sidney F. Ascher, 42 Cherrydale Ave., Springfield, Mass., Student

Robert S. Drews, M.D., Dr.P.H., 3263 Joy Rd., Detroit, Mich., Student

Viola G. Pfrommer, Colby Junior College, New London, N. H., Chairman, Dept. of Health and Physical Education

Lewis C. Robbins, M.D., C.P.H., State Board of Health, Indianapolis, Ind., Local Health Administrator

K. Frances Scott, M.D., 33 State St., Northampton, Mass., Associate Professor of Hygiene, Smith College

Richard H. Shryock, Ph.D., Department of History, University of Pennsylvania, Philadelphia, Pa.

H. D. Voorhies, D.D.S., 2002 N. Hallock St., Kansas City, Kans., Assistant City Dentist

Public Health Nursing Section

M. Grace Fate, R.N., 221 Third St., Peoria, Ill., Staff Nurse, Health Dept.

Winnifred H. Jarvis, 19 North 2nd East, Brigham, Utah, City Public Health Nurse

Maria Johnson, Latter Day Saint Hospital, Salt Lake City, Utah, Superintendent of Nursing

Ima Martin, R.N., Milledgeville, Ga., Itinerant District Nurse, State Dept. of Public Health

Ila Z. Moore, 1115 E. High St., Jefferson City, Mo., Field Advisory Nurse, State Dept. of Health

Ellen Perdue, 314-14 St., Denver, Colo., Superintendent, Denver Visiting Nurse Association

Jessie M. Roach, Romney, W. Va., Hampshire County Public Health Nurse

Bertha B. Stevens, R.N., 475 E. Walnut, Springfield, Mo., District Public Health Nurse, State Board of Health

Epidemiology Section

George M. Leiby, M.D., Dr.P.H., State Board of Health, Raleigh, N. C., Consultant, Venereal Disease Control, Division of Epidemiology

Atilio Macchiavello, M.D., Dr.P.H., Casilla 3629, Santiago de Chile, S. A., General Director of Public Health

William E. Mosher, Jr., M.D., 65 Court St., Buffalo, N. Y., Epidemiologist-in-training, State Dept. of Health

Unaffiliated

Frederick Birnberg, D.D.S., 40 E. 49 St., New York, N. Y., Dentist, Department of Health

Marvin Liebman, 27 Lines St., New Haven, Conn., Student

DECEASED MEMBERS

R. S. Copeland, M.D., New York, N. Y., Elected Member 1918, Fellow 1922. Life Member 1936

Paul Eaton, M.D., Orange Park, Fla., Elected Member 1930

John N. Force, M.D., Dr.P.H., Berkeley, Calif., Elected Member 1920, Fellow 1934

Maurice C. Hall, Ph.D., D.V.M., Washington, D. C., Elected Member 1936

Vera H. Jones, M.D., Denver, Colo., Elected Member 1936

Renwick H. Leitch, D.Sc., Auchincruive, Ayr, Scotland, Elected Member 1933

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Nurse Placement Service, 8 South Michigan Avenue, Chicago, Ill., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS AVAILABLE

Two positions as medical director of county health units are open in Wisconsin. Duties largely administrative. Counties both rural, populations 15,000 and 40,000. Salaries: \$3,300 per annum plus approximately \$600 for travel. Applications may be sent to:

Dr. H. V. Gibson, Director
County Health Unit
Court House Annex
Eau Claire, Wis.

Dr. Milton Trautmann
State Board of Health
Madison, Wis.

POSITIONS WANTED

HEALTH OFFICERS

Physician, M.D., Class A medical school; M.P.H., Harvard School of Public Health; extensive experience in pediatrics and school medical service; also background of county health administration and teaching in medical school, will consider expanded opportunity in teaching or research. A302

Physician, M.D., St. Louis University; postgraduate in eye, ear, nose and throat; 10 years' experience in public health administration as director of county health units and epidemiologist with state department; also experienced in welfare administration, prefers administrative public health position in central or western state. Excellent references. A373

Physician, M.D., McGill; C.P.H., Johns Hopkins; excellent background of communicable disease control and school health service, seeks position as epidemiologist or public health administrator. A368

Experienced physician, administrator, epidemiologist, and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Experienced administrative health officer with excellent background is available for a responsible position with adequate salary. A375

Physician, M.D., Class A school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer, seeks full-time administrative position in city or county. A367

Physician, experienced in health administration of cities and states, will consider attractive opening in maternal and child health or health education. A343

Physician with Dr.P.H. degree from Yale, now employed by state department of health, will consider position in general health administration, in infant welfare or in epidemiology. A300

Physician, long experienced in public health laboratory work and general administration, will consider attractive position. A295

MATERNAL AND CHILD HEALTH

Woman physician with excellent medical training and background of public health nursing experience, seeks position in maternity and infancy work. C376

Specially qualified and experienced physician in maternal and child health, has been director of state and local maternity programs, will consider a responsible position. A238

Woman physician, graduate of University of Iowa, who has directed state bureau of maternal and child health, now employed, will consider another position. C318

HEALTH EDUCATION

Well qualified woman in health education wishes position as health coordinator or health counselor. Has wide experience and Ph.D. from New York University. M236

Woman, M.D., Boston University; special work Columbia and Massachusetts Institute of Technology; interested in psychiatry; with one year's experience in State Hospital, desires position in the East in hospital for mental diseases or industrial school. H248

MISCELLANEOUS

Physician, graduate of Johns Hopkins Medical School and well qualified in medicine and tuberculosis, will consider a clinical position in the medical field. M377

Laboratory position desired by well trained bacteriologist and immunologist in routine laboratory or research work. L312

Experienced teacher in bacteriology and public health; Ph.D., Cornell; now professor in Grade A medical school, will consider teaching, executive or administrative position. M327

NEWS FROM THE FIELD

Proposed Tuberculosis Program

A SIX year federal and state spending program to bring about the control of tuberculosis was approved by the board of directors of the National Tuberculosis Association at its annual meeting in Los Angeles, June 20.

It was proposed that the plan be sponsored by the federal government, and that part of the costs be obtained from states and local governments after the manner in which highways, parks and other improvements are arranged.

out that tuberculosis could be brought under national control.*

Since that time Mr. Homer Folks has been working out the plan. He laid the general principles of it before the board of directors of the National Tuberculosis Association last February and received their approval for a continuance of the study with a special committee of the association of which Mr. Folks was chairman. The program presented is, in effect, the report of that committee.

COSTS OF TUBERCULOSIS CONTROL PROGRAM AS ESTIMATED TO GO THROUGH 6 YEAR PERIOD

The following is a summary of the costs on a chronological basis of the tuberculosis control program advocated by the National Tuberculosis Association:

<i>Fiscal Year</i>	<i>Hospital Construction</i>	<i>Hospital Maintenance</i>	<i>Case Finding</i>	<i>Total Six-Year Program</i>
1939-40.....	\$5,000,000	\$7,000,000	\$500,000	\$12,500,000
1940-41.....	35,000,000	10,000,000	1,000,000	46,000,000
1941-42.....	35,000,000	16,000,000	2,000,000	53,000,000
1942-43.....	35,000,000	22,000,000	3,000,000	60,000,000
1943-44.....	30,000,000	28,000,000	4,000,000	62,000,000
1944-45.....	30,000,000	5,544,000	35,544,000
	<u>\$140,000,000</u>	<u>\$113,000,000</u>	<u>\$15,544,000</u>	<u>\$269,044,000</u>

Estimated Federal participation by year and by purpose and total (construction at 80 per cent participation; maintenance and case finding at 50 per cent).

<i>Fiscal Year</i>	<i>Hospital Construction</i>	<i>Hospital Maintenance</i>	<i>Case Finding</i>	<i>Total Six-Year Program</i>
1939-40.....	\$4,000,000	\$3,500,000	\$250,000	\$7,750,000
1940-41.....	28,000,000	5,000,000	500,000	33,500,000
1941-42.....	28,000,000	8,000,000	1,000,000	37,000,000
1942-43.....	28,000,000	11,000,000	1,500,000	40,500,000
1943-44.....	24,000,000	14,000,000	2,000,000	40,000,000
1944-45.....	15,000,000	2,772,000	17,772,000
	<u>\$112,000,000</u>	<u>\$56,500,000</u>	<u>\$8,022,000</u>	<u>\$176,522,000</u>

Such a program of control has been a topic of conversation among experts in the campaign against this disease since the time, 2 years ago, when the late Dr. Wade H. Frost, epidemiologist of Johns Hopkins University, pointed

The program, as outlined, states as its general objective "to reduce tuberculosis throughout the United States in

* Frost, W. H. How Much Control Tuberculosis? *A.J.P.H.*, 27, 8:759 (Aug.), 1937.

the shortest possible time to a negligible factor in morbidity and mortality" and special objectives are to raise to the highest adequacy and efficiency tuberculosis control measures in all sections, and to intensify efforts in the best areas. Experimental demonstrations of case finding among the entire population or selected groups, and more adequate home relief for tuberculosis families, before, during, and after hospitalization of the patient, are suggested as special measures in these areas.

MOST ESSENTIAL MEASURES LISTED

"For the purposes of the program it is assumed that the most essential and immediately effective measures are:

(1) case finding, including X-ray examination, among those who have been exposed to tuberculosis by family contact; (2) provision of hospital care for all cases of tuberculosis discovered needing such care, especially for sputum-positive patients; (3) federal leadership and financial aid, with actual operation generally left to state and local authorities . . ."

In estimating the annual costs of the 6 year program, 1939 to 1945, the report fixes the total at \$269,044,000, including \$140,000,000 for new construction, \$113,000,000 for hospital maintenance, \$15,544,000 for case finding. Maintenance and case-finding costs would not reach the maximum until the 6th year.

ASSOCIATION OF WOMEN IN PUBLIC HEALTH PLAN ALL-DAY MEETING FOR OCTOBER 24

THE Association of Women in Public Health is planning an all-day meeting immediately prior to the Annual Meeting of the American Public Health Association. As president, Sally Lucas Jean, Health Section Secretariat of the World Federation of Education Associations, announces 4 important sessions to be held on October 24. Three of these are scheduled at The Elms Hotel, Excelsior Springs, Mo.; the 4th, an evening banquet, at the Muehlebach Hotel, Kansas City, Mo.

Because Excelsior Springs is enroute to Kansas City for those travelling from the East, many members of the Association and guests are planning to spend the week-end at this famous health resort. Accordingly an informal tea has been scheduled for Sunday afternoon, October 23, to meet the officers of the Association and the committee on local arrangements.

At 9:30 Monday, October 24, the first session will meet in the drawing

room of The Elms Hotel. A series of 10 minute talks on problems and programs affecting the specialists comprising the group will open this session. Women experts in health education, medicine, social hygiene, mental hygiene, maternal care, public health nursing, to mention a few of the interests of the group, will crystallize their ideas in their specific fields before the meeting is thrown open to the entire group.

At 1 p.m., also at The Elms Hotel, an open luncheon meeting will take up the subject of health centers from the angles of the preparation of the worker, rural and urban problems, lay understanding and participation, and the contribution of the various specialists to the problem.

At 3:30 the business meeting will be held to act upon the new constitution upon which the constitution committee has been working for the past year.

At 6:30 the annual banquet will be

held at the Hotel Muehlebach, Kansas City, when three prominent speakers will survey the field from the standpoint of past performance, present program, and future progress through lay support and participation. This banquet meeting will be open to all public health workers, men and women, and their staunch supporters in public health objectives—the public.

Rosamond Losh, executive secretary, Children's Bureau, 1020 McGee Street, Kansas City, Mo., is serving as chairman of the committee on arrangements. The Elms Hotel, Excelsior Springs, has arranged a special over-Sunday rate for those who plan a restful week-end under this roof. Those arriving on Saturday and leaving after luncheon on Monday will be accommodated at a flat rate of \$11.25 per person. This rate includes luncheon and dinner on Saturday, 3 meals on Sunday, breakfast and luncheon on Monday. Guests will occupy double rooms. Therapeutic baths may be arranged for if desired. For those arriving on Sunday evening a rate of \$5.00 will carry through the luncheon on Monday. As golf, horseback riding, tennis, beautiful drives and walks are all available at The Elms no Sunday program of events has been arranged. On October 22 an exhibition of fancy swimming and diving may be observed at the Hall of Waters.

SHELLFISH CONTROL

AQUARANTINE on mussels growing within the area from the southern boundary of Los Angeles County to the Oregon Line, exclusive of San Francisco Bay, has been established by the California State Department of Health.

The quarantine, which will continue through July, August, and September, prohibits the taking, sale or offering for sale of mussels growing within this area.

KANSAS COUNTY HEALTH OFFICERS

THE following County Health Officers have recently been appointed in Kansas:

Dr. Edwin R. Hill, Jr., Lyons—Rice County
 Dr. August A. Meyer, Alma—Wabaunsee County
 Dr. Orlin P. Wood, Marysville—Marshall County
 Dr. Alfred J. Horejsi, Ellsworth—Ellsworth County
 Dr. Benjamin Brunner, Wamego—Pottawatomie County
 Dr. Raymond W. Moore, Eureka—Greenwood County
 Dr. Frank A. Trump, Ottawa—Franklin County
 Dr. Franklin R. Croson, Clay Center—Clay County
 Dr. Benjamin L. Phillips, Paola—Miami County
 Dr. Leon W. Zimmerman, Liberal—Seward County
 Dr. Ivan B. Parker, Hill City—Graham County

The following reappointments have been announced:

Dr. Spencer B. Dykes, Esbon—Jewell County
 Dr. Robert J. Lanning, Junction City—Geary County
 Dr. Donald A. Bitzer, Washington—Washington County

OHIO FEDERATION OFFICERS

NEW officers were elected at the convention of the Ohio Federation of Public Health Officials, April 29, as follows:

President—R. H. Markwith, M.D., Akron
Vice-President—H. H. Pansing, M.D., Dayton
Secretary-Treasurer—W. D. Bishop, M.D., Greenville
Delegate—George D. Lummis, M.D., Middletown

VENEREAL DISEASE CONTROL IN VIRGINIA

ANNOUNCEMENT has been made of a program for the control of venereal disease in Richmond, Va., under the directorship of Dr. Francis W. Upshur, a graduate of the Medical College of Virginia.

PUBLIC HEALTH NURSE PLACEMENT

ON July 1, 1938, the Public Health Nursing Division of Joint Vocational Service, New York, N. Y., was transferred to Nurse Placement Service, 8 South Michigan Avenue, Chicago, Ill. The National Organization for Public Health Nursing approves this placement bureau, and is acting as an intermediary in the transfer of records at the request of registrants.

Elizabeth J. Mackenzie, R.N., Associate Director, Henry Street Visiting Nurse Service, New York, will become Assistant in the development of public health nursing vocational work as a member of the staff of Nurse Placement Service.

Anna L. Tittman, R.N., formerly Vocational Secretary for Public Health Nursing of Joint Vocational Service, is now Executive Director of Nurse Placement Service.

PARROTS BARRED IN NEW YORK

THE New York State Commissioner of Health recently announced that a sanitary code regulation prohibiting the importation, breeding or sale of birds of the psittacine or parrot family became effective June 1. A similar regulation will go into effect in New York City on July 1.

COORDINATION IN NEW YORK CITY

A JOINT committee representing the New York City Department of Health and the Board of Education has been established to coordinate problems relating to the welfare of pupils. The Department of Health has jurisdiction over the physicians and nurses, and the Board of Education bureau of health education supervises the general health program.

This is the first permanent committee to be set up to coordinate action on health problems by the two depart-

ments. Chest X-ray examinations for tuberculosis as well as other health undertakings will be made possible with the cooperation of the health department. Advice and counsel to school officers will be provided by the health department, together with medical examination to pupils.

MISSOURI PUBLIC HEALTH ASSOCIATION

THE Missouri Public Health Association held its 14th Annual meeting in Jefferson City on May 13-14, with an attendance of 125 public health workers.

Among the speakers were Governor Lloyd C. Stark, Dr. Thomas Parran and Dr. W. K. Sharp of the U. S. Public Health Service, and Dr. Frances C. Rothert of the U. S. Children's Bureau.

The following officers were elected:

President—Merl P. Moon, Ph.D.

President-Elect—Theodore R. Meyer, M.D.

1st Vice-President—Asa Barnes, M.D.

2nd Vice-President—Raphael Heyburn, R.N.

Treasurer—L. E. Ordeltcheide

Secretary—John W. Williams, Jr., M.D.

STREAM POLLUTION STUDY

PLANS are under way for the construction of a new Public Health Service laboratory in Cincinnati, Ohio, to house the Stream Pollution Investigations Division of the National Institute of Health. The present laboratory, located in the former Marine Hospital building, has carried on work in methods of combating stream pollution for the benefit of waterworks systems throughout the entire country.

VIRGINIA HEALTH UNIT

A NEW full-time health department began functioning in Buchanan County, Va., July 1. Since April 1, 1936, the county's health activities were conducted as a part of a district

composed of Tazewell, Russell, and Buchanan Counties.

Headquarters for the new unit will be in Grundy, Va.

PERSONALS

Central States

DR. OLIVER S. CRAISE, of Towner, N. D., has been appointed Superintendent of the McHenry County Board of Health.

DR. EDMUND STEPHEN DONOHUE, of Gregory, S. D., has been appointed Superintendent of the Gregory County Board of Health.

DR. FRANCIS WELDON FORD, of Minnewaukan, N. D., has been appointed Health Officer of Devils Lake.

DR. RUSSELL R. HANSEN has been appointed Health Officer of Storm Lake, Ia., succeeding DR. EDGAR F. SMITH, who recently resigned after 8 years in the position.

ENOCH M. PORTER, M.D., of Great Falls, Mont., was elected President of the State Board of Health at its recent meeting in Helena.

DR. ARTHUR W. RECORDS has been appointed a member of the Franklin, Ind., Board of Health, to succeed the late DR. DANIEL R. SAUNDERS.

WILLIAM D. STOVALL, M.D.,* Professor of Hygiene, University of Wisconsin Medical School, Madison, Wis., has been appointed acting superintendent of the State of Wisconsin General Hospital, Madison, during the leave of absence of ROBIN C. BUERKI, M.D., to become Director of Study of the Commission on Graduate Medical Education.

ROBERT GILLAM WHITE, M.D.,† formerly of Ann Arbor, Mich., has been appointed to take charge of a new district branch of the North Dakota State Department of Health, with headquarters at Valley City.

Eastern States

JAMES L. BARRON, C.E.,* of White Plains, N. Y., resigned July 1 : Director of the Division of Sanitation of the Westchester County Department of Health. Mr. Barron will become County Sanitary Engineer and will organize a division of sanitation for the Department of Health in Nassau County, N. Y.

DR. FRANCIS BREWER has been appointed Health Officer of Brookfield, Conn.

RUFUS I. COLE, M.D., D.Sc.,† was recently honored at a dinner at the Rockefeller Institute for Medical Research. A bound set of volumes of reprints from the Institute hospital, from which he resigned as Director last year, was presented to Dr. Cole.

DR. WILLIAM L. HIGGINS has been appointed Health Officer of Andover, Conn.

DR. GEORGE S. LAMBERT has been appointed Health Officer of Killingly, Conn.

HARRY B. MELLER,† Managing Director of Air Hygiene Foundation, Pittsburgh, Pa., had the honorary degree of Doctor of Science conferred upon him by the University of Toledo, at the University's 55th annual commencement June 13. He is a Senior Fellow at Mellon Institute and has been in charge of air hygiene researches at that institution for 20 years.

HUGH G. ROWELL, M.D.,† is now associate adviser and associate chairman of the Department of Education of the Handicapped, at Teachers College, Columbia University, and Physician to the Horace Mann School, Teachers College, New York.

DR. JOSEPH L. ROY has been appointed Health Officer of Thompson, Conn.

* Fellow A.P.H.A.

† Member A.P.H.A.

GEORGE C. SHATTUCK, M.D.,† who has been for many years chairman of the executive committee of the Boston Health League, Boston, Mass., has recently become chairman of the Medical Advisory Committee of the Health Commissioner of Boston; chairman of the Advisory Committee for School Hygiene, City of Boston, for the director of the Department of School Hygiene; and president of the Massachusetts Central Health Council.

Southern States

JUSTIN M. ANDREWS, Sc.D.,† Associate Professor of Protozoology, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md., has been appointed Director of the Division of Malaria Investigation of the Georgia State Department of Health.

RALPH G. BEACHLEY, M.D.,* Deputy Director of Rural Health in the Virginia State Department of Health, has been appointed Health Officer of Arlington County, to succeed EARLE G. BROWN, M.D.,* who recently became Health Officer of Nassau County, at Mineola, N. Y.

DR. WILLIAM Y. GARRETT, of Raven, Va., has been appointed Health Officer of Prince William County.

GEORGE W. MAST, M.D.,† Director of the Holmes County Health Department, Lexington, Miss., has been appointed Director of the Washington County Health Department, Greenville, succeeding JOHN W. SHACKELFORD, M.D., M.P.H.,† resigned.

KENNETH F. MAXCY, M.D.,* has resigned as Professor and head of the Department of Bacteriology at Johns Hopkins University School of Hygiene and Public Health, to become Professor and head of the Department of Epidemiology. He re-

tains temporarily his former position as Professor of Bacteriology at the School.

DR. JOHN A. MILNE,† of Jackson, Miss., has been appointed Director of County Health Work of the Mississippi State Department of Health, succeeding HENRY C. RICKS, M.D., C.P.H.,† resigned.

HENRY C. RICKS, M.D., C.P.H.,† for 10 years Director of County Health Work of the Mississippi State Department of Health, Jackson, Miss., was appointed Director of the State Hygienic Laboratory, effective May 1, following the retirement of THEODORE W. KEMMERER, M.S., M.D.,* who has served 14 years as Director. CHARLES L. SAVAGE, M.D.,† of Charlottesville, Va., recently Director of the health unit of Tazewell, Russell, and Buchanan Counties, has been appointed Director of the Hanover County health unit, with headquarters in Ashland.

JOHN W. SHACKELFORD, M.D., M.P.H.,† of Greenville, Miss., for 8 years Director of the Washington County Health Department, has resigned to become Director of the technical field unit and serve as Advisory Officer for Health Units with the Oklahoma State Department of Health.

ALVIN L. STEBBINS, M.D.,† of Punta Gorda, Fla., has been appointed Health Officer of Escambia County, succeeding WILLIAM H. PICKETT, M.D.,* of Pensacola, resigned. Dr. Stebbins has recently been Health Officer of Franklin, Gulf, Liberty, and Calhoun Counties.

RAYMOND A. VONDERLEHR, M.D.,† Assistant Surgeon General, U. S. Public Health Service, Washington, D. C., dedicated the new venereal disease clinic to be operated by the Caddo-Shreveport Health Unit, Shreveport.

* Fellow A.P.H.A.
† Member A.P.H.A.

La. Four hundred patients daily will be accommodated in this clinic for syphilis and gonorrhea. This parish consists of approximately 45 per cent Negroes.

Western States

ELMER MCK. BINGHAM, M.D.,† of San Luis Obispo, Calif., Health Officer of Yolo County, has been appointed Health Officer in San Luis Obispo County, succeeding ALLEN F. GILLIHAN, M.D.,* retired due to ill health.

DR. NEIL F. BLACK, of Klamath Falls, Ore., Health Officer of Klamath County, has been appointed State Medical Relief Coördinator.

DR. JOSEPH M. BROWN has been appointed Health Officer of Ferndale, Calif., to succeed DR. OLIVER B. BARRON.

SETH H. MILES, M.D., of Santa Monica, Calif., has been appointed Health Officer of Mono County, succeeding ROBERT K. HARKER, M.D.,† of Bridgeport.

HARRY W. PASLEY has been appointed Health Officer of Reedley, Calif., to succeed DR. ROY E. ALLEN.

DR. ENOCH M. PORTER, of Great Falls, Mont., has been elected President of the Montana State Board of Health, at its recent meeting in Helena.

JOHN O. RAFFETY, M.D.,† of Oakland, Calif., has been appointed Health Officer of Yolo County, succeeding ELMER MCK. BINGHAM, M.D.,†

ROLLO J. SHALE, M.D.,† has been appointed full-time Health Officer of Weld County, Colo., with offices in Greeley. Weld County is the second full-time unit recently established in Colorado.

DR. ELLIS D. SOX, of Berkeley, Calif., has been appointed Health Officer of Tulare County; the unit has recently been placed on a full-time

basis. ELMO R. ZUMWALT, M.D.,† of Tulare, Health Officer of the unit on the former basis, continued as part-time Health Officer until June 1.

Canada

DR. BRABAZON J. HALLOWES has been appointed Health Officer of Alexis Creek, B. C.

DR. DONALD H. WILLIAMS, of Vancouver, B. C., has been appointed Director of the Division of Venereal Disease Control of the Department of Health of British Columbia.

England

DR. ELWIN H. T. NASH, Medical Officer of Health for the Borough of Heston and Ilseworth, has been elected President of the Society of Medical Officers of Health of England for the session 1938-1939.

DEATHS

JOHN N. FORCE, M.D., DR.P.H.,* of the University of California, Berkeley, Calif., recently died suddenly.

JAMES H. FOSTER, of Albany, N. Y., Director of the Child Aid Bureau of the New York State Social Welfare Department, died May 9, after 30 years' service in the state's employ. MARY LUCIER,† died in Rochester, Minn., on July 10.

JOHN J. MULLOWNEY, M.D.,* since 1921 Professor of Public Health, and President of Meharry Medical College, Nashville, Tenn., retired July 1. Dr. Mullowney was Assistant Chief of the Pennsylvania State Department of Health 1913-1917, and head of the Department of Science and Professor of Chemistry and Hygiene, Girard College, Philadelphia, Pa., 1917-1921. His successor is DR. EDWARD L. TURNER.

* Fellow A.P.H.A.

† Member A.P.H.A.

Health Hazards in the Dry Cleaning Industry

A Preliminary Report of a Survey of Dry Cleaning Establishments in the Detroit Metropolitan Area

WILLIAM H. CARY, JR., C.E., F.A.P.H.A., AND
JOHN M. HEPLER, C.E.

*Former Sanitary Engineer, Bureau of Industrial Hygiene, Department
of Health, Detroit, Mich.; and Director, Bureau of Industrial
Hygiene, State Department of Health, Lansing, Mich.*

THE chief purpose of this investigation has been to determine the working conditions in the dry cleaning industry, with emphasis on its outstanding health hazards. In order to obtain a true picture of the industry as it serves a large and concentrated population and in order to eliminate those variables which ordinances or regulations might impose within the city limits, the survey was extended to the Detroit metropolitan area. Since plants coming under the jurisdiction of both the Michigan and the Detroit Departments of Health were involved in the survey, their respective Bureaus of Industrial Hygiene coöperated in the field work and the preparation of this report.

The area covered includes all of the incorporated municipalities adjacent to and contributing to the life of the City of Detroit and certain well populated unincorporated areas. Not included

are largely open agricultural sections devoted to farming and truck gardening.

From departments which license such establishments and from fire chiefs and other public officials, an original list of dry cleaning establishments was created. This list was supplemented from other sources, such as telephone directories and classified advertising, until not only all plants actually doing cleaning were located and inspected but all "pick-up" stations as well were visited to make sure that cleaning on a small scale was not being overlooked.

The investigation may be termed a preliminary engineering survey to determine the types of equipment and kinds of solvents used, number of employees involved, existing and potential health hazards, control measures provided, and the medical or first aid requirements needed or provided. Some qualitative and quantitative measure-

ments of the concentration of vapors and gases present in the establishments were made, but no attempt at determining the physical condition of the individual employee was undertaken.

TRADE PRACTICES

The dry cleaning industry has been subject to continuous innovation. In the beginning, dry cleaning was accomplished merely by dipping. The solvent, originally gasoline or an equivalent, was merely placed in a tub, and in this was submerged the garment to be cleaned. Repeated explosions and fires quickly demonstrated the danger of this practice.

The original tub dipping has almost entirely disappeared. Primitive methods have given way to enclosed or partly closed systems. In some, at least, of the highly developed devices, cleaning and drying take place in one operation without the necessity of opening the container, and thus without introducing a high concentration of vapors into the work room. The shift from the completely open system using tubs or vats to the semi-closed or completely closed systems has been brought about primarily by legal or economic pressure. Fire and explosion hazards have rightly led to regulations in most cities and states. Upon the introduction of non-flammable solvents, it was found that wastage through evaporation in the open systems made the use of these more costly agents uneconomical. As a consequence, in late years there has been a definite trend toward closed systems. If the worker, through the operation of closed systems, is less exposed to the evaporation of solvents, and if these devices obviate the necessity of hand contact with these damaging agents, it manifestly follows that the workers are less likely to be injured through the inhalation of poisonous vapors or to acquire skin diseases through contact with cleaning liquids.

Experience with closed systems tends to emphasize the dangers from dry cleaning processes carried out in completely open systems and in those semi-closed systems which still provide opportunities for the creation of dangerous quantities of vapors and for skin contact with the substances employed.

All considered, it is necessary to recognize that many health hazards are widely prevalent in the dry cleaning industry; that legal restrictions adequate to the situation have not been provided in many localities; and that advantages have been taken with respect to the many opportunities for the evasion of such legal provisions as have been instituted. Moreover, it is apparent that health officials have not been fully cognizant of the extent of the dangers that, at least theoretically, and to some extent practically, reside in the trade practices attending dry cleaning.

Few commercial dry cleaners limit themselves to one place of business. Many dry cleaning establishments maintain central plants, and in addition scores of stations without any facilities for actual dry cleaning, which serve primarily as intake or delivery points. In some instances, these "pick-up" stations are owned and operated by the management of the central plant, but for the most part, they are privately owned and served by the central plant on a wholesale basis. In addition to the "pick-up" stations, the industry employs a large number of salesmen or drivers. These men usually cover a prescribed territory and are employed on a salary plus or straight commission basis. The operation of stations for pick-up and delivery work provides opportunities for the location of the actual dry cleaning plants outside city limits. This may introduce occasion for avoidance of compliance with local regulations.

Dry cleaning is commonly associated with garments such as suits and dresses.

While these articles do make up the great majority of fabrics subjected to cleaning, a fair amount of dry cleaning is extended to carpets, rugs, hats, leather goods, fur and animal hair products. However, the fundamental practices are substantially the same in all branches of the industry. Typical high grade practices are now described.

When the garments reach the dry cleaning plant, they are marked for identification. They are next searched and all articles removed from the pockets. As a first step in the actual cleaning, all cuffs and seams are brushed, after which the clothing is placed in the washer. Modern practice requires that the garments be washed until the solvent being circulated through the machine comes from the washer clear and free from turbidity. All during the washing process, the solvent is being passed through a "closed" system, from the washer to a filter or other cleansing unit and back into the washer. Sight glasses on the influent and effluent lines give the cleaner ample opportunity for careful observation of the progress of each wash.

In closed systems, the garments are extracted and dried in the washer itself. After the cleansing is complete, the solvent is drawn off, the washer speeded up in order that the major portion of the solvent in the garments may be removed by centrifugal force. Following this, quantities of hot air are passed through the machine. As an economy measure, where halogenated hydrocarbons are used as cleaning fluids, an attempt is usually made to recover the solvent from the discharged air. This is done by the use of refrigeration, cold water coils or activated carbon filters. Theoretically at least, garments come from such systems entirely free from any traces of solvents. Practically, this was not found to be so.

In other installations, the garments

are removed from the washer by hand and placed in a centrifuge extractor. After being extracted as dry as possible in this machine, they are placed in a tumbler. The tumbler consists of a rotating cylinder through which hot air is passed until the garments are dried. The exhaust from the tumblers is generally discharged directly into the atmosphere outside the building.

About 10 per cent of the garments that are dry cleaned require spotting. The spotter, who is a real artist in his work, must diagnose the cause of each spot or stain, since different cleaning agents are needed, according to the cause of each. After the spots have been removed, the garments rejoin the other 90 per cent for the final operation of pressing. Steam presses are generally used, and the operation is a familiar one, known to all who have occasion to visit tailoring and pressing shops.

For garments of delicate texture, different handling is needed. The types of washers vary somewhat from the standard rotary washer and the drying process varies from that already described. The latter is accomplished by hanging the garments in a special room or chamber into which hot air is forced. The final step of pressing is hand work instead of steam press work as with the heavier garments.

Naturally, the processes just described do not apply to all systems of dry cleaning. There are extremes beyond and modifications between all the methods listed.

QUALITIES DESIRED IN A SOLVENT

A solvent, in order to be suitable for dry cleaning processes, must have several important properties.

1. It must be cheap and readily available.
2. It must be a reasonably good solvent for greases and body waste products.
3. It must be inert to the fabrics to be cleaned in it and to the dyes as well.

4. It must lend itself to some purification processes for reclamation purposes when it becomes dirty.

5. It must be sufficiently volatile in order that its complete removal from cleaned fabrics may be rapidly accomplished without objectionable residual odors.

6. It must have a high flash point in order to reduce explosion and fire risks.

7. It must be dry (containing no water and having no alcoholic properties).

8. Lastly, but of prime consideration, it must possess a low order of toxicity.

In the earlier days of dry cleaning, benzine (gasoline) was used. The danger of explosion and the fire hazard early resulted in its replacement by cleaners' naphtha (boiling point 200°F.-325°F., flash point approximately 25°F.), a petroleum fraction. Frequent explosions and fires, resulting in damaged goods and high insurance rates, led to the introduction of Stoddard's solvent, a petroleum fraction (maximum boiling point 410°F., flash point 104°F.). While this solvent possesses low toxic properties, fire insurance regulations permit its use only under certain definite and sometimes inconvenient conditions. For years the use of a non-flammable solvent has been recognized as desirable, but the only commercially available ones, carbon tetrachloride and chloroform, were too expensive for wide use. With the introduction of cracked petroleum and the subsequent utilization of the unsaturated gaseous by-products, many new halogenated solvents became available. All met the requirements of a dry cleaning solvent very well and many of them are just now being introduced to the industry. Recently, to avoid the embarrassment of fire regulations, a new petroleum fraction, F-140 (flash point 140°F.), has been introduced but is still in the developmental stage.

The following list includes the chief solvents which are available for use either individually or in combination with one another.

Benzol (C_6H_6)	Dichlorethylene
Petroleum naphtha	Trichlorethylene
Stoddard's solvent	1,1,1-trichlorethane
Gasoline	1,1,2-trichlorethane
F-140	1,1,1,2-tetrachlorethane
Carbon tetrachloride	Ethylene dichloride

CHEMISTRY OF SOLVENTS IN COMMON USE

In general, petroleum fractions are very stable and enter into chemical reactions only with unusually reactive agents or under extreme conditions of temperature and pressure. Unquestionably the presence of small amounts of impurities in the solvents as a result of the process of manufacturing may be of consequence, but the usual method of treating solvents in the dry cleaning plant is well designed to remove such impurities. In the routine use of the solvent with the addition of many kinds of detergents and the accumulation of body waste, dirt and the like, it probably picks up impurities of a nature harmful to the cleaner. If an adequate reclamation system is in use in the plant, no danger should arise. These facts emphasize the need for satisfactory purification systems.

When the halogenated hydrocarbons or the so-called synthetic solvents are considered, the situation is quite different. These solvents as a class are relatively active. In the presence of alkalis, they tend to split off chlorine with the formation of alkali chlorides; in the presence of water they tend to hydrolyze with the formation of hydrogen chloride or hydrochloric acid depending upon the amount of water present. The compounds are susceptible of rather easy oxidation so that in the presence of atmospheric oxygen, certain decomposition compounds may be formed. Halogenated solvent vapor, when exposed to light and atmospheric oxygen, or elevated temperatures such as are produced on contact with hot steam pipes, may become oxidized with the formation of carbonyl chloride

(phosgene) and chlorine. The well known toxicity of phosgene possibly may, in some instances, enter into the totality of exposures connected with halogenated hydrocarbon vapors. Due to these chemical changes, it becomes apparent that if halogenated hydrocarbons are to be used for dry cleaning solvents, they should be used in completely closed systems, no chemicals which promote their decomposition should be added, and no high temperatures should be employed if atmospheric oxygen is present.

Furthermore, special care should be taken in the selection of materials for use in the construction of machinery, if the metal of that machinery is to come into contact with the solvent, lest the metal activate undesirable decomposition. The intelligent and proper use of halogenated solvents in the dry cleaning industry or in any other industry cannot be too highly emphasized.

SPOTTING AGENTS

Spotting is an art requiring long experience and good judgment on the part of the spotter. Each one will have certain chemicals or mixtures which he believes to be most effective on a type of spot or stain. For this reason, it is not easy to compile a list of chemicals which may be found at any individual spotting board, but one may compile a list of chemicals which might be encountered in an inspection of a number of dry cleaning plants. While many chemicals are used in spotting processes, most spots are removed with water, dilute acetic acid, or dilute ammonium hydroxide. The following list includes most of the chemicals which are used either alone or in combination for spotting processes.

MOTH-PROOFING

Many attempts have been made to apply moth-proofing materials to garments in the dry cleaning plant. Older

SPOTTING AGENTS

Acetic acid	Isopropyl alcohol
Acetone	Lactic acid
Ammonium hydroxide	Lysol
Amyl acetate	Magnesium carbonate
Amyl alcohol	Methanol
Benzene	Oleic acid
Butylcellosolve	Oxalic acid
Borax	Potassium
Carbon disulphide	permanganate
Carbon tetrachloride	Pyridine
Castor oil	Rapid acting enzymes
Chloride of lime (calcium chloro-hypochlorite)	for albumen, etc.
Chloroform	Sodium cyanide (rare)
Citric acid	Sodium hydrosulphite
Cresylic acid	Sodium chloride
Diethyl ether	Sodium lauryl sulphonate
Dry-cleaning soap	Sodium perborate
Ethyl acetate	Sodium sulphite
Ethyl alcohol denatured with methanol	Sodium thiosulphite
Ethylene dichloride	Sulphonated oils
Ethylene glycol	Sulphurous acid
Glycerine (Glycerol)	Tetrachlorethane
Hydrofluoric acid	Tetralin
Hydrochloric acid	Trichlorethylene
Hydrogen peroxide	Tri-sodium phosphate
Hexolin	Triethanolamine
	Water
	Xylene

methods involve spraying the garments with arsenic compounds, which, although they give adequate protection to the garments, exposed both the workers and the wearers of the garments to the dangers of arsenic poisoning. Furthermore, spraying of the individual garments greatly increased the cost of handling. Inasmuch as moth-proofing was usually offered as a free service, it was not profitable to conduct the operation. Recently various moth-proofing preparations have appeared which are added directly to the solvent, from which they are preferentially absorbed by the clothes. Obviously, this method of moth-proofing is economically practical since it involves no additional labor for its accomplishment. Inasmuch as the cost of the preparations is not great, the cost of the treatment is not only negligible, but yields good returns in advertising value. Such preparations

are expected to come into general use within the next few years.

No information is available as to the exact ingredients of these preparations since in every case the manufacturer is keeping the formula secret. As far as is known, no reliable data are available as to their toxicity to man.

A survey of patent literature and other sources shows that many chemicals have been proposed for this purpose. The following list includes some of these materials:

INGREDIENTS OF MOTH-PROOFING PREPARATIONS

1. The condensation products of Isatin-5-sulphonic acid with amyl cresol (acid condensing agent)
2. The condensation products of Isatin-5-sulphonic acid with p-tert-amyl phenol (acid condensing agent)
3. The condensation products of N-benzylisatin sulphonic acid with thymol (in presence of stannic chloride, SnCl_4)
4. Sodium aluminum silica fluoride
5. Chloroxylenols (mixed)
6. Trinitro-isobutyl-xylene
7. Sodium fluoride
8. Sodium taurocholate
9. p-nitro-chlorobenzene
10. Dichlorobenzene
11. Fluoro-derivatives of naphthalene, biphenyl, aniline, phenol, acetic acid and methane
12. 1,2,3,4-tetrahydronaphthalene
13. 3,4 - dichlorobenzenesulphomethylamide and diethylbutylglycolphosphate
14. 3,4 - dichlorobenzenesulphodiethylamide and tri-isoamylphosphate
15. 3,4-dichlorobenzenesulphobutylamide and tritolylphosphate
16. 90% propylene dichloride and 10% carbon tetrachloride
17. Sodium arsenite solutions
18. Solvent naphtha or diphenyl methane, diphenylethane or biphenyl
19. 1,3-dichlorobenzene-4-sulpho-1, 3-phenylene-diamine plus diethylbutylglycol phosphate
20. Sodium 3',5', 4"-pentachloro 2,2'-dimethoxytriphenyl methane - 2" - sulphonic acid. Other substituted triaryl methanes may be used.
21. p-dichlorobenzene
22. Naphthalene

It is expected that in the near future many dry cleaners will have some kind of vault-type moth-proof storage avail-

able. The most familiar is cold storage, the cold being provided by artificial refrigeration usually employing sulphur dioxide, methyl chloride, or carbon dioxide as a refrigerating gas, since ammonia machines are too expensive to operate on such small installations. This type of storage introduces the dangers of commercial refrigeration to the industry.

Another popular type of moth-proofing storage is that recommended by the U. S. Bureau of Standards. This method involves the storage of clothes in an atmosphere the humidity of which is properly controlled and the temperature of which is permitted to vary through a certain specified range. An advantage of this system lies in the fact that moth larvae are actually killed in this environment.

A third method involves fumigation of the clothes with some type of gas toxic to the moths and their larvae. Formerly hydrogen cyanide was commonly used for this purpose. At the present time a new gas, "malium," is being widely used. These three types of storage may be used individually or in some combination with one another.

It is impossible at the present time to evaluate the hazards which this new phase of the dry cleaning industry has introduced.

RETEXTURING

In the manufacture of textiles, especially woolen and silk materials, an important part of the process consists in adding some type of oil or lubricant to the fabric. The presence of such oils improves the sheen and texture, increases the wearing quality, and makes the fabric water-repellent. Unfortunately, dry cleaning effectively removes these oils or lubricants from the fabrics with the result that a frequently dry cleaned garment becomes dull in appearance and tends to wear out quickly due to the friction of

unlubricated fibers on one another. Recently, attempts have been made to remedy this condition. The problem of retexturing is still in the research and developmental state, but its use even now is beginning to appear in a few dry cleaning plants and it is safe to predict that within the next few years retexturing will become as important a part of the dry cleaning process as pressing the clean garment. The retexturing agent must be completely absorbed by the fiber itself without leaving an external greasy film. Paraffin wax, dibutyl phthalate, aluminum stearate, diglycololeate and glycolboriborate, chlorinated derivatives of naphthalene, anthracene, biphenyl ether and various sulphonated oils may be used and, in some instances, are being used as lustering and retexturing agents. Inasmuch as virtually nothing is known concerning the toxicity of these substances, it is not possible to appraise these hazards, but only to suggest that the toxicity of these materials must be investigated at some time in the near future.

RECLAMATION OF SOLVENTS

In the course of ordinary use the dry cleaning solvents become contaminated with grease, mechanical dirt, dye, unsaturated compounds, waste products of the body, and various soaps and detergents used as cleaning agents. Reclamation processes fall definitely into two groups, chemical and physical. Both may be applied to the stable petroleum fractions, but only physical methods may be used for halogenated solvents owing to their inherent instability.

Two chemical methods are in common use. One is the so-called "continuous" caustic settling system in which process the solvent to be reclaimed is bubbled through a strong potassium hydroxide solution in a large tank. Separation of the solvent from the chemical is effected by gravity.

The waste sludge is periodically withdrawn from the tank, which is then recharged with fresh caustic solution.

The second method, which is distinctly superior in effectiveness, is a so-called "batch" process. A convenient volume of solvent and a proportionate volume of concentrated commercial sulphuric acid are placed in a special tank and the whole thoroughly mixed. The concentrated acid is used to prevent the decomposition of the steel tank and pipes. This treatment renders most of the impurities water soluble. The batch is then thoroughly washed with water until the wash water is neutral. A small amount of concentrated potassium hydroxide is added, mixed, and washed out with water until neutral. The solvent is now considered ready for use.

Several physical methods are available, the most effective of which is that of distillation. This is usually done with a large capacity vacuum still of the continuous type. About once a week depending upon the condition of the solvent, the still must be opened and cleaned out. This is usually a hazardous task, as the operator is exposed to an accumulation of waste material and to a high concentration of organic vapor.

The next most generally used method, frequently used concurrently with distillation, is that of continuous pressure filtration. While several types of filters are used, they all utilize the principle of circulating the solvent through a filter medium supported either on a bag or on a monel metal screen. Filter powder is added directly to the solvent. Some common powders are Filteraid, Fuller's Earth, diatomaceous earth, diatomaceous silica, activated silica, or activated alumina. A further treatment frequently utilized with continuous filter systems involves the addition of a finely powdered activated carbon to the solvent. This preferentially absorbs unsat-

urated hydrocarbons, body wastes, and pigmenting substances from the solution.

Another physical purification method now virtually obsolete involves purely mechanical centrifugal clarification. The dirty solvent is passed through a centrifugal machine similar to a cream separator, thus removing, mechanically, particles from the solution. Obviously this method of treatment will not remove dissolved impurities.

In modern dry cleaning plants reclamation is accomplished by a combination of distillation, continuous pressure filtration, and activated carbon. Needless to say, only this type of procedure is available for the reclamation of halogenated organic solvents.

HOME DRY CLEANING

Since the principal cost of dry cleaning arises in the finishing and delivery of the garments rather than in their actual cleaning, a considerable apparent saving can be effected by conducting dry cleaning at home thus avoiding the latter charges.

Such dry cleaning operations are usually conducted by the housewife in the basement or kitchen of the home. The clothes are washed in an open vessel containing cleaner's naphtha, which may be purchased at popular prices at almost any filling station. This material is flammable and its vapors may be readily ignited by static sparks produced by friction of silk garments upon one another, open flames, hot stoves, faulty electrical connections, washing machine and vacuum cleaner motors, electric irons, toasters and other household electrical appliances. Even such a simple operation as turning off or on an electric light may provide the necessary spark. As a result, serious accidents arising from home dry cleaning operations are common. This danger may be minimized to a certain extent by working out of doors on a rainy day when the humidity is high. This

avoids the accumulation of high vapor concentrations in confined places and reduces the danger from static sparks. This latter danger is especially high on a clear winter day and in any heated house.

To eliminate the fire hazard, so-called fire-proof or safety solvents have been introduced. These solvents consist of cleaner's naphtha, with enough chlorinated hydrocarbon solvent, such as carbon tetrachloride, added to raise the flash point beyond the danger zone. Unfortunately the vapors of such solvents are much more toxic than those of cleaner's naphtha due to the presence of chlorinated compounds. The only end gained is the replacement of a fire hazard with an almost equally serious health hazard. The use of a comparatively non-flammable petroleum fraction such as Stoddard's solvent is not feasible, due to the difficulty of driving the residual solvent and odor from the fabric without the use of heat.

When all aspects of the situation are taken into consideration, it is very doubtful if dry cleaning at home affords to the housewife a real economy since the great fire and health hazards combined with the definitely inferior cleaning clearly offset the few dollars a year saved. In most instances, careful selection of fabrics at the time of purchase, accompanied by properly conducted wet-wash methods will produce results superior to home dry cleaning and at no risk to the housewife. Under few, if any, circumstances, can dry cleaning at home be considered a wise practice.

SOAPS AND DETERGENTS

Successful dry cleaning with petroleum solvents cannot be accomplished unless some emulsifying agent or water bearing agent is added to the solvent. Such additions are necessary in order to keep mechanical dirt in suspension in the solvent until it may be removed by a filter or some other process and

to permit a certain amount of solution of materials which are insoluble in organic solvents. These agents fall into 4 classes:

1. Aqueous agents such as ammonium hydroxide and alcohol. Many cleaners add large quantities of ammonium hydroxide to the solvent, sufficient, in fact, to give it a strong ammoniacal odor.

2. Soaps—The soaps are the most important class. In order that they may be reasonably soluble in the solvent, one of the potash salts of the various fatty acids must be used. The most commonly used are the potash salts of oleic, palmitic, and stearic acids. Many of these soaps are either insufficiently soluble or their emulsions are of such large particle size that their salts will not pass through a pressure filter such as is used by the industry without their partial or complete removal from the solvents. Hence, special "filter" soaps are necessary for use in filter systems and differ from other soaps largely in that special emulsifying agents have been added which greatly reduce the particle size of the soap suspension.

3. Aqueous solutions of such materials are sodium carbonate, borax, trisodium phosphate, and the like.

4. Emulsifying agents such as sulphonated oils, sulphonated long chain alcohols, esters such as diglyco-oleate and hydrogenated aromatic compounds (for instance tetralin and hexalin).

The present trend in detergents is definitely toward the sulphonated oils, for example, sulphonated cocoanut oil, sulphonated palm oil, sulphonated fish oils.

In order to give a picture of the chemical composition of some typical soaps and other detergents, a few formulae are included.

In general, the potassium salts of stearic, palmitic, and oleic acids, the triethanolamine salts of fatty acids,

sulphonated oils, sulphonated alcohols, long chain alcohols such as cetyl alcohol, ethylene glycol esters of fatty acids and aqueous solutions of ammonia, alcohol, trisodium phosphate, sodium carbonate, and the like are used.

"PICK-UP" STATIONS

In addition to the 97 plants investigated, 828 "pick-up" stations were visited during the course of this survey. No attempt was made to list their employees, but several points of interest were investigated. It was first determined whether any dry cleaning was actually carried on at the premises or whether it was all sent to an established plant. A number of small plants that

to high temperatures from steam. In addition, some of these pressers are exposed to carbon monoxide fumes because of no fume pipe or an improper fume pipe on the steam boilers, or defective boilers. Although this survey was conducted in the summer and early fall when doors and windows were generally wide open, fumes from the burners were noticeable in many stations. This was particularly true in the case of the small oil burning type.

LEGISLATION

For years, many cities and states have enforced ordinances or regulations for the construction of dry cleaning plants and for the conduct of the industry. At the time most of these ordinances or regulations were enacted, naphtha and gasoline were almost universally used as the solvents, and as a consequence extreme fire hazards existed. Legislation, therefore, was designed to reduce the fire hazard in the plant and to adjoining property. Little or no concern was given to any health hazard which might be present. With the introduction of synthetic solvents possessing no fire hazards, plant owners saw an opportunity of getting away from such regulations and of conducting their businesses in existing structures.

With few exceptions, state laws and local ordinances define the industry; regulate the type of building and location in which it may be conducted; describe in some detail the heating, lighting, and ventilation of said buildings; indicate within limits the construction of the equipment that may be used; and stipulate the conditions governing the storage, handling, refinement, and use of the solvents. Little more could be asked if such laws included protection for the health of the workers. There are two important shortcomings in our present laws. In defin-

ing the industry, only those enterprises employing a solvent of a flammable or explosive nature are usually included. Further, with rare exception, the regulations are designed not entirely to rid the atmosphere of solvent vapors but merely to keep the concentration of such vapors below the explosive range. Since the synthetic solvents used in the industry are classed as non-flammable and non-explosive, most existing regulations or laws do not govern their use.

Notice is taken that some few states, such as Ohio, have provided codes limiting the use of chlorinated hydrocarbons to closed systems.

TOXICITY AND CLINICAL MANIFESTATIONS

Because of space limitation, all reference to physiologic properties of solvents, clinical manifestations, frequency of cases, and methods of diagnosis are omitted. Discussions of this character may readily be found in the publications of the Smyths, Hayhurst, McCord, Smith, Lamson, Wirtzschafter, and many others.

Of greater importance for the present presentation, is the bringing to light of scores of substances widely used in the dry cleaning industry which are little known to industrial hygienists, at least under the circumstances attending dry cleaning work. At the present time, appraisal of these little known substances in terms of toxic properties constitutes a greater need than further elaboration upon the properties of better known solvents.

Apart from the exposures that may grow out of the large number of agents directly used in cleaning work, and the reclamation of cleaning materials, a few other hazards, chiefly of physical nature, have been encountered. The outstanding ones are now briefly mentioned.

Excessive Temperature—The steam press operators are subjected to the heat from presses. This condition is particularly bad in places where the presses are not equipped with motor driven vacuum exhausts. To a lesser extent, hand pressers using electric hand irons are also subject to some high temperatures. In Table IV showing numbers exposed to various hazards, this latter group is not included as exposed to excessive temperatures.

TABLE IV
Employee Exposure

<i>Exposure</i>	<i>Male</i>	<i>Female</i>	<i>Total</i>

Tenovitis	0	377	377
Posture	340	191	531
Carbon Monoxide	98	0	98
Total	1,425	973	2,398

Posture—The steam press operators are also subject to the hazards of posture. In operating the presses they are required to use both feet as well as their hands.

Excessive Moisture—The steam cleaners are the persons who do the wet washing and work generally under poor conditions. With their scrub brush and board they are usually located in the basement or in some out of the way corner of the building. The very nature of their occupation subjects them to constant wetting and only by the use of rubber boots and aprons are they able to keep even a semblance of dryness.

Tenovitis—The hand pressers are subject to a possible inflammation of the cords in the backs of their hands from the constant lifting and pressure on the irons.

Carbon Monoxide — Firemen and boiler operators are at least theoretic-

cally, if not practically, subject to carbon monoxide poisoning.

INSTRUMENTATION

In the conduct of this survey, three procedures chiefly have been utilized in the determination of the concentration of vapors present:

1. A combustible gas indicator, of special design, permitting of the measurement of gases and vapors in toxic as well as explosive ranges.

2. A halogen lamp, which chiefly affords qualitative information. This was particularly useful in tracing the spread of toxic chlorinated hydrocarbon vapors emanating from known points.

3. The quantitative determination of chlorinated hydrocarbon vapors through activated charcoal absorption.

SUMMARY

This report embraces the findings of an engineering investigation of the dry cleaning industry in the City of Detroit and its environs. Ninety-seven dry cleaning plants were investigated, together with 828 "pick-up" stations. This is a progress report, which, in many phases, especially with respect to medical and analytical data, is incomplete. From information now on hand it appears:

1. The total number of dangerous substances used in dry cleaning and ancillary operations is far in excess of the small number customarily associated with the dry cleaning industry. Scores of agents have some use

TABLE V

which so far as is known have never been adequately investigated in connection with possible toxic properties.

2. In every instance of the use of chlorinated solvents or mixtures of chlorinated solvents with petroleum fractions as primary dry cleaning fluids, a definite exposure was found to exist. If these solvents are to be safely used in this industry, an extensive revision of current operating practices is in order.

3. With few exceptions, the use of Stoddard's Specification Solvent probably presents a minimum of hazard arising from the inhalation of vapors.

4. In most instances where very volatile petroleum fractions such as cleaner's naphtha and gasoline were used, unsafe concentrations of the vapors of these solvents were found to exist.

5. Regardless of the type of solvent in use,

almost without exception some degree of dermatitis occurs on the hands and arms of workers. In many instances the degree of injury is trivial and of slight duration.

6. It is not yet possible safely to evaluate the exposures arising from the use of such new high-boiling petroleum fractions as the F-140, type.

7. Fancy spotters are undoubtedly exposed to a wide variety of solvent vapors as well as other chemicals, but the extent of this exposure is difficult to quantitate for the industry as a whole. Unquestionably, in specific instances, spotters have been exposed to chlorinated solvent vapors as much as cleaners working with these solvents.

8. In general, it is believed that the other hazards of the industry such as unnatural postures, tenovitis, excessive humidity, moisture, heat, and carbon monoxide are of minor significance.

Marrying a Nurse

W. E. TANNER recalled how some years ago Sir Cooper Perry had given the following advice to those who contemplated marrying a nurse, viz.: "Notice what shoes she wears, see her in mufti, and visit her parents." Mr. Tanner said that whatever a nurse might do when in mufti, when they knew in all truth that sweet artifice might be necessary, a nurse

should remember that the beautiful simplicity of her uniform did not lend itself to the excessive use of rouge, lipstick, and the darker shades of nail varnish. Complete cleanliness, absolute tidiness, and well-shod feet were the complementary essentials of the scientifically trained practical nurse.—*Editorial Notes. J. Roy. Inst. Pub. Health & Hyg., July, 1938.*

Methods of Estimating Postcensal Populations*

HENRY S. SHRYOCK, JR., PH.D.

School of Public Affairs, Princeton University, Princeton, N. J.

ESTIMATES of population for the contemporary years after a federal census have been made by highly approximate methods for the states, cities, and counties in the United States. The degree of inaccuracy tends to vary directly with the time elapsed since the census, and inversely with the size of the population. Within 3 or 4 years' time the seriousness of the error for any of these types of areas is, on the average, large enough to render most uncertain comparisons of vital rates from year to year or from place to place. The value of population estimates in their numerous other applications is also impaired.

It should not be thought, however, that no progress has been made in the methodology of estimation since the U. S. Bureau of the Census and other agencies first began to make estimates. The bureau's adoption of the so-called "apportionment method" represented a definite advance over the earlier method of arithmetic increase. Recognition of the fact that postcensal estimates should be based upon contemporary data for the given area rather than upon merely some hypothesis of growth was another important step for-

ward toward the creation of improved methods and technics. Attention is now being focused upon potential sources of such data and upon means of making them more useful as bases of population estimates.

Accordingly, methods that rest solely upon a hypothesis of growth will be dismissed with a bare mention. They include arithmetic and geometric progression, the fitting and extrapolation of other mathematical curves (especially the Pearl-Reed Curve), and the empirical procedure of Thompson and Whelton.¹

From 1926 until 1934 the Bureau of the Census made its estimates for state and city populations by the apportionment formula. This formula assumes that the estimated postcensal increase in the national population was divided among these states or cities according to their shares in the national increase of the previous intercensal decade. The official state estimates for 1934, 1935, and 1936 were based upon vital statistics and elementary school enrollment data in a manner that will be described below. Censuses taken by 5 states were also utilized. The bureau has released no city estimates since 1933, and there have been no official estimates of the population of counties since the last census.²

There is not much of a problem remaining in the calculation of estimates

* Read at a Joint Session of the American Statistical Association and the Vital Statistics Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

for the total population of continental United States. The excess of births over deaths and the difference between immigration and emigration are added cumulatively each year to the population at the last census. The only unknown quantities are the amount of underregistration of births and deaths and the extent of illegal immigration. Corrections have been made for the first two of these. Underregistration of births is certainly the most important of the three. It may have amounted to about 8 per cent of all births during the first half of the present decade. Yet despite these uncertainties, the bureau was able to estimate the population of the United States just prior to the last census date with an error of only ± 0.15 per cent.

Despite the experimentation that has been carried on from time to time in the Bureau of the Census and elsewhere, state and city estimates still pose a formidable problem. The unsatisfactory results of the apportionment formula are indicated by an average error of 6.88 per cent* for state populations computed for April 1, 1930. The corresponding average error for cities having 10,000 or more inhabitants in 1920 was far greater.

Let us first consider methods of making postcensal population estimates for states. For these, as for cities and counties, school statistics are the series of contemporary data that generally have the highest combined degree of utility, uniformity, and availability. The writer has demonstrated elsewhere³ that any reasonable use of the elementary⁴ school enrollment data collected from the states by the U. S. Office of Education yielded an average error for 1930 state populations that was significantly lower than that cited above for the apportionment formula.

The best of these had an average error of 4.21 per cent. The corresponding root-mean-square deviations about zero per cent error were 10.14 per cent for apportionment and 6.32 per cent for enrollment. Further experimentation showed that enrollment data by age (rather than by grade) of comparable accuracy with those in the "School Attendance" chapter of the U. S. Census volumes could reduce, with proper manipulation, this average error to between 2 and 3 per cent. Unfortunately, such data are not now readily available for more than a few states.

While working at the Bureau of the Census in 1936, John D. Durand and the writer devised a somewhat similar method using existing data on enrollment in elementary grades. This method has been called the "migration and natural increase" method, and it was essentially the one used in the official state estimates for 1934, 1935, and 1936. It is a very elaborate and time consuming procedure. Essentially, however, the method falls into two parts. The difference between registered births and deaths, both corrected for underregistration, is considered as the postcensal natural increase and is added to the state population at the last census. The net interstate migration of school children is estimated from a state's actual and expected elementary school enrollment. The migratory gain or loss in this group is prorated to persons of all ages. The final net change due to migration is then added to the calculated natural increase and the census population to get the postcensal estimate. The main source of difficulty is finding the school enrollment that was expected had there been no migration. The detailed procedure is to be found only in unpublished reports.

There has not yet been an opportunity to test the method for a sufficiently large number of cases to

* Throughout this paper the term "average error" denotes mean percentage deviation from the enumerated population, disregarding the sign of the error.

define its relative worth with any degree of accuracy. A check against 8 state censuses taken from 1934 to 1936 showed an average error of 3.04 per cent. This average compares favorably with one of 3.84 per cent for the same states estimated by the apportionment formula. By all logical considerations this method is superior to the simpler ones using school enrollment, and it has already been shown that these give better results than the apportionment formula.

Nevertheless, we should strive rapidly to improve upon this new method for states. It has many obvious weaknesses, and we are certain that the resulting estimates are not in general adequate for the vital statistician. In a recent investigation undertaken at Princeton University, Durand demonstrated that wide margins of error in the estimated net migration result from necessary approximations in calculating the ratio of enrollment in grades 1-8 to enrollment in a given age group, such as 6-14. This difficulty could be eliminated by obtaining actual enrollment by age as the basic data. Accurate school censuses with carefully defined age limits would further simplify the method. Unfortunately, Durand also found that 28 school censuses taken in 1930 deviated by an average of 4.2 per cent from the enumerations of the same age group made by the federal census. Only 9 deviated by less than 2 per cent.

Other original work on methods utilizing elementary school enrollment is being carried on by Paul V. Lane of the California Taxpayer's Association.⁵ He too has made separate estimates of population change from natural increase and net migration. His expected enrollment was arrived at by a study of the progression of school children through the grades. Enrollment in grades 2-7 in one year less "normal losses" (from death, with-

drawal, and retardation) is compared with enrollment in grades 3-8 the next year. The difference is attributed to net migration. Apparently, however, no essentially satisfactory method has yet been found for ascertaining the rate of these "normal losses" in the schools of a given area. Lane's method may be applied equally well to cities and counties if births and deaths are properly allocated by residence.

School statistics might be improved so as to present accurate data on enrollment by age in all schools, private as well as public, corrected for the actual residence of the child; or they might take the form of school census figures collected every year, giving age at last birthday. These valuable data still would be able to inform us about the migratory movements of only a minority of the population. Inferences about the corresponding movements of persons in other age groups, particularly adults without young children, would remain highly speculative.

There are for most states but few contemporary series of statistics that can be used to supplement school data. One possible source is the registered deaths for specific age groups by sex and color. Lane and Durand independently worked out technics for utilizing such data in population estimates. Assuming that the specific death rates of 1930 for states have remained unchanged to the postcensal year or have changed in some specified way, they divided these rates into the corresponding registered deaths to obtain estimates of the population in the specific age groups.

It was found best to estimate only the population above school age by this method and to get the number of persons of school age and preschool age from school statistics and registered births. Durand has also tried limiting the procedure to deaths from non-epi-

demographic causes. Although this approach involves a degree of circular reasoning when the estimates are applied to the calculation of crude death rates, it is far superior to population estimation based on total registered deaths and the crude death rate at the last census. In the very few comparisons that could be made with estimates from the migration and natural increase method, the latter appeared to be more satisfactory.

Let us now turn to postcensal estimates for cities. These are in general even worse than those for states, but there is a continually large demand for them. For city school enrollments the U. S. Office of Education does not make a separate classification of grades 1-8, but such data usually are available in local reports. The migration and natural increase method used for states is not readily applicable to cities. On the average, but by no means in all cases, school statistics even when used alone give more accurate results for cities than the apportionment formula. The major problem is to estimate the ratio of enrolled or enumerated children to the population of all ages. This is a surprisingly variable ratio. Over the period 1930 to 1935 this variability led to an average error of 6.52 per cent * in the population estimates for Massachusetts cities or towns of 10,000 or more inhabitants.

By way of compensation, there are many more series of pertinent contemporary data for cities than for states. These include the number of listings in city directories, population counts from real property inventories, and public utility records of consumers. All of these usually require extensive refinement. They may be used to supplement one another or school statistics.

Durand devoted considerable study to the contents of city directories when he was with the Bureau of the Census. Very often the number of individuals listed can be obtained only from the publisher. Other limitations are failure to confine the listings to the corporate area of the city, duplication through listing of an individual both at his residence and at his business address, and changes in the minimum age required for inclusion.

During 1934 real property inventories were taken by the United States Bureau of Foreign and Domestic Commerce in many large or medium sized cities. Since then others have also been financed from work relief funds. Most of the surveys included an enumeration of persons living in families. From the relationship of family and quasi-family or institutional population in 1930, the number of persons not living in families may be estimated. The sum of the enumerated family population and the derived quasi-family population represents an estimate of the total population. Of the 64 cities included in the 1934 real property inventories of the U. S. Bureau of Foreign and Domestic Commerce, 7 were also covered by recent state censuses. After adjustment to the proper date, the average discrepancy for these 7 was found to be 3.80 per cent.

The records of utility companies on domestic consumers of water, gas, and electricity, and telephone subscribers are moderately useful for population estimates. The chief weaknesses of these series lie in their close dependence upon economic conditions and in the difficulty of isolating the figures for the city proper, exclusive of suburbs. So few city populations have been estimated from the same type of public utility data that it is impossible to say more than that this source does not appear at present to be especially promising.

* Estimates were made from school census of children 7-13 inclusive and the 1930 ratio. The estimates were compared with the returns of the 1935 state census.

It may be recalled that state populations have been estimated from resident births, school enrollment, and age-specific deaths. These three series could be used for the age groups 0-4, 5-14, and 15 and over, respectively. Similar composite estimates can be made for cities. For example, the 1934 populations of 13 Massachusetts cities or towns having 25,000 or more inhabitants in 1930 were estimated from registered births, school enrollment, and directory listings. The average error was 3.40 per cent. When directory listings and school enrollment had been used separately the average errors were 6.03 and 3.77 per cent, respectively. Similar experimentation on other cities indicates that this approach is a promising one.

Another technic may be used when several series of data are available that do not apply to different age groups. If a list of city or state populations is being estimated, we may find the means of the corresponding estimates from two or more different methods. The average error of the series of combined estimates may be lower than the average error of any of the original series. This effect is obtained only when the errors by the original methods are not too disparate and when the corresponding errors are not correlated. For instance, three unrelated methods for the above 13 Massachusetts cities yielded 1934 estimates with average errors of 2.71, 3.40, and 3.40 per cent. The arithmetic mean of these estimates had an average error of only 2.31 per cent. It may also be remembered that the apportionment formula gave an average error of 6.88 per cent for state estimates as of 1930 and that a method using public elementary school enrollment gave one of 4.21 per cent. If the two estimates for each state are averaged we obtain a new average error for all state of only 3.71 per cent.

This technic of combining estimates has the disadvantage of giving larger errors for some of the populations in the series than those given by the best of the original methods. Very often one method may be superior to another in one section of the United States or in certain parts of a state but inferior in others. Where such a situation is known it is clearly the more sensible procedure to use different methods for different areas. However, one must study the relative worth of various methods to see whether in a particular state or city the past superiority of an otherwise inferior method represents part of a consistent pattern or merely a chance relationship.

From the size of the errors cited in this paper it can be seen that postcensal estimates despite recent improvements in methodology are still too inaccurate for scientific and most administrative uses. The writer feels that the greatest improvement in the future will come not from new technics or methods but from the exploitation of new series of contemporary data and the refinement of old ones. The Bureau of the Census ought to have a permanent section for making postcensal estimates of population. Meanwhile state and city planning boards and health departments should not be content with the arithmetic method or with curve-fitting. In their own experimentation they can test local material much more exhaustively than the Bureau of the Census can ever do. Although much progress thus may be made, it is not likely to remove the imperative need for more frequent federal censuses, supplemented by sample enumerations and locally undertaken census, or for a population register.

"Federal Money is Not Manna from Heaven"

EDWARD S. Godfrey, Jr., M.D., New York State Commissioner of Health, in an address at the Conference of Health Officers and Public Health Nurses at Saratoga Springs recently, warned that federal funds allotted to New York State and to the several states for public health services should be spent wisely or not at all. "Even more important," he said, "these federal grants cannot replace current expenditures and must not replace local expenditures that might have been appropriated for health work were federal grants not available. State and federal expenditures must serve to stimulate local interest and local expenditure for the control of communicable disease."

Dr. Godfrey asserted that states and local governments must not lean heavily on the federal government for assistance in essential health services but rather the states must reserve every essential state right and must not fall into the dangerous tendency akin to

that of relief clients looking to the government for their living. "Not only must we not become confirmed dependents; we must not become dependents at all. We must exert ourselves and use our resources to assist in every way possible to effect the early eradication of preventable disease."

Dr. Godfrey added that the public must understand that the provision of 1 nurse for 10,000 to 20,000 people must be regarded as wholly inadequate and that a nursing service on this scale merely touches the surface. It is also too superficial to produce a public impression. It can never implement the programs for the reduction of infant and maternal mortality, the rehabilitation of crippled children, the eradication of tuberculosis and of syphilis, or the reduction in pneumonia mortality—each and all of which we have every reason to believe the public wants us to do, that we want to do and that we can do if we are given the support we need.

Handicaps in the Normal Growth and Development of Rural Negro Children

HILDRUS A. POINDEXTER, M.D.

*Professor of Bacteriology, Preventive Medicine and Public Health,
Howard University, Washington, D. C.; and Temporary
Epidemiologist in Charge of a Rural Health Unit
in Glendora, Miss.*

THE worth while racial potentialities of Negro infants born and reared in rural southern environment are not sufficiently well developed at chronological maturity to make them either a local community asset or prepare them for respectable social adjustment elsewhere. The longer one observes large cross-sections of these Negroes, the more true this statement appears to be.

One might expect that the unnecessarily high death rates among the young children, due to the operation of the law of "survival of the fittest," would eliminate the weak and leave only the strong. In many sections of the lowlands, if only the physical stature of the young adult is considered, the expectation is confirmed to some extent. If, on the other hand, one considers the whole individual; his physical and mental attributes, and his personality, together with their interrelationship, the wholesome, positive qualities are few.

The problem of the handicapped rural Negro is becoming increasingly serious. He is becoming more and more recognized as the reservoir for certain diseases, such as the venereal diseases and malaria. He is propagating an increasingly large percentage of the race and is becoming more responsible for a stigmatizing increase of juvenile de-

linquency and young adult crime. Many of the factors contributing to the latter two categories are due to the blind migration from the rural areas to metropolitan centers, and to his not being prepared for a respectable adjustment in a more complex society. He increases the city relief rolls and unemployment, and also becomes easy prey to temptations and criminal exploitations of his own race and the white race.

The rural Negro child is handicapped in normal growth and development, not only because he harbors certain microorganisms that are associated with his environment, but by lack of socio-intellectual facilities and opportunities. If one agrees with Patry¹ that "when the healthy person is in a state of dynamic balance on all levels of integration—structural, physiologic, biochemical, endocrine, neurologic, and psychologic—he feels adequate in meeting life vicissitudes," one must admit that very few of the rural Negroes born and reared in the southern states become healthy adults.

I list and briefly discuss the four major interrelated handicaps which are interfering with the normal physical, mental, emotional, and social growth and development of rural Negro children in the "cotton belt." The basis

for these opinions comes from the writer's personal observations while in the service of a hospital in Alabama in 1929, and from two special surveys, in which a social epidemiological analysis was made of the findings from a physical, stool and blood examination of 706 rural Negroes in Bullock County, Ala., in 1934,² and of 1,975 rural Negroes in Tallahatchie County, Miss., in 1937.

FIRST MAJOR HANDICAP

NON-INFECTIOUS MALNUTRITION

Non-infectious malnutrition is an arbitrary designation for a group of children whose physical findings and social history show that they are below par, but in whom the laboratory examinations and history do not reveal either hookworm, malaria, syphilis, or tuberculosis infection or infestation.

In our Alabama survey, 18 per cent of the children come under this group. In the Delta region of Mississippi only 7 per cent of the children come under this group, but in the hilly sections of the state the percentage was as high as in Alabama. These children were anemic (hemoglobin below 75 per cent), their muscles were flabby, their posture was poor, and many showed pyogenic and pellagic conditions of the skin. Sore eyes were common, and more than 50 per cent of those over 8 years showed some degree of dental caries.

This state of non-infectious malnutrition has been observed for many years by representatives of the various state boards of health, but only rarely does this group of individuals appear in their annual reports as a significant rural health problem. It seems as though the mental and physical state of asthenia among these rural Negro children are accepted as relative normalities for the group. This is not a wholesome attitude.

An analysis of the families from which the children of this group come

showed not only environmental lack of sanitation, but a history of a deficient diet for 5 to 7 months out of each year, during which, meal, meat, and molasses were the diet of the old and the young. This is true in spite of the fact that both the climate and the land on which they live are suitable for the growth of different vegetables the year round. One of the great needs for the families of this group is instruction in how to raise and properly store what they need on the land that they till, even at the expense of an acre of cotton more or less.

SECOND MAJOR HANDICAP

SYPHILIS

In metropolitan areas the high incidence of syphilis and tuberculosis generally comes from the same locality and group. However, in our surveys we found that this was not the case in rural areas; the exception being the young adult female.

The rural areas of the southern states, more than at any other time in many decades, are now the weakest link in our public health chain. The health status of the Negro is important to all because he makes up several of these weak links, and when the problem is "syphilis control," he becomes a dominant segment of the chain. The rural Negro, due to no fault of his own, is becoming more and more the reservoir for syphilis in the United States. Three factors seem to play a large part in this increasing prevalence:

1. There are increased opportunities for exposure. Due to better transportation facilities, the rural Negro farmer goes to the small town or village every Saturday. Finding no provision for his wholesome recreation, the small town prostitutes become his means of relaxation, stimulated by the much too common use of alcoholic beverages. The rural Negro does not have proper information concerning venereal disease prophylaxis, becomes infected, and in due time infects other members of his family and community.

2. The aimless town-to-town migration of

the young male adult who with promiscuity and favor spreads the disease along his pathway. These "floating fathers" play an important part in the family history of congenital syphilis and illegitimacy.

3. There is a lack of facilities for the diagnosis, treatment, and follow up; and until recently, there was a definite apathy on the part of the white people in the community toward this condition.

According to physical examinations and standard complement-fixation and precipitation serology tests, 14 per cent of the children under 20 years of age in the Mississippi survey had syphilis. Because of histories of early sexual practices in some, the congenital and acquired cases in this group were not separated. The incidence of those between 20 and 34 years of age was 31 per cent. The number of children tested for syphilis in the Alabama group was too small for analysis, but the percentage of those between 20 and 34 years of age with syphilis was 27 per cent. Even though practically all of the people covered by our survey were poor and of low intelligence, the highest incidence of these syphilitics under 20 years of age come from families where even greater poverty and ignorance exist.

The chances of the children of untreated syphilitic women becoming a community asset are not good. In many cases, the results of conception are abortion, stillbirth, or a syphilitic live baby, weakened by the effects of the *Treponema pallidum* and apt to die very early in life. If, however, he lives to later childhood or even adulthood, there are the syphilitic physical and even mental stigmata to be reckoned with as social problems. In both our Mississippi and Alabama groups of these young syphilitics, in addition to the presence of an anemia and flabby muscles, there were also some of the classical stigmata of eyes, ears, mouth, and nose or bony changes. In addition to the physical handicaps, there were

frequent instances of psychobiological disharmony. It was difficult to tell how much of this was due to lack of opportunities for educational development in the whole community and how much to the presence of the *Treponema pallidum* and the physical defects associated with it. We saw one case of a 13 year old congenital syphilitic with juvenile paresis. The problem of gonorrhea in the young children in these communities is very serious. It is augmented by ignorance and many superstitious ideas and practices which make the young virgin girl a target for attacks which are generally not reported. These superstitious practices often result in infection and pregnancy in these children.

THIRD MAJOR HANDICAP

MALARIA

The southern states, from South Carolina to Texas inclusive, show that malaria fever is 4.2 to 6 times as prevalent in Negroes as in whites.³ In our study in Bullock County, Ala., in 1934,⁴ 16 per cent of the Negro children between 5 and 21 years of age showed malaria parasites in their blood upon a single thick blood smear examination, even though acute symptoms were not pronounced. In our Mississippi study in 1937 for the same age group, although only 12 per cent gave positive blood smears, the frequent history of "chills and fever" cured by quinine and the high splenic index lead us to believe that the incidence of malaria is greater in the Delta of Mississippi than in Bullock County, Ala.

The children in this group were generally anemic, asthenic, and lethargic. This is easily understood when one realizes the damage to the reticulo-endothelial system resulting from the deposition of pigment coming from the degenerating plasmodia and red blood corpuscles, the toxin given off by the disintegrating plasmodia, and the sensi-

tizing effect of this toxin on the red blood corpuscles. The resulting fragility predisposes these red blood corpuscles to mechanical and chemical damage. The anemia which follows is a big factor as a handicap of the growing child. In families where the malaria cases were found, only 1 out of every 47 dwellings was properly screened.

FOURTH MAJOR HANDICAP HOOKWORM INFESTATION

Where repeated stool examinations were made, the incidence of hookworm infestation in children between the ages of 9 and 14 years (the age of greatest prevalence) may be as high as 20 per cent. In Bullock County, Ala., we found that 11.7 per cent of the children of 9 to 14 years, showed hookworm ova by a single stool examination. The incidence was higher in boys than in girls. In all positive cases, there was a history of wading or swimming in ponds or creeks. The houses in general did not have sanitary privies or they were not properly used. The incidence of hookworm in the Delta region of Mississippi is much lower than in Alabama or the hills of Mississippi.

Very few of the Negro children who showed ova in their stools had any severe symptoms. They were, however, anemic (some with hemoglobin as low as 40 per cent) and asthenic. Many had sores on their lower extremities. The pathological anemia seems to be the most significant finding. This, we believe, is due to the action of the adult hookworm which attaches itself to the intestinal mucosa after its larval migration and moulting. Not only is there a mechanical loss of blood with the corresponding depletion of iron and calcium, but a definite anticoagulant toxic product is given off by the hookworm which affects the hematopoietic system.

In hookworm infection, as in some

of the other infections, the finding of the organism does not explain all of the symptoms of the disease. We know that if a child had an adequate diet containing inorganic iron, liver, or milk, he would not show the marked symptom of hookworm disease that one occasionally sees. The solution to this problem is greater than merely rendering the child temporarily free from the nematode.

SOME GENERAL UNDERLYING FACTORS

The chief factors responsible for the conditions listed here are ignorance and poverty, to which must be added inadequate social agencies to alleviate the conditions in this group. In the 1937 annual report of the American Social Hygiene Association,⁵ many agencies were listed as participating in the association's programs in various communities. In the Delta regions of the southern states, where the health problems of the rural Negro in regard to certain diseases appear worst, the agencies listed in the association reports⁵ are almost nonexistent or non-functional. Only in a few instances do the official health departments or the boards of education consider the expenditure and activities for promotion of the normal growth and development of the rural Negro child in an unbiased light. The Negro has no race representation and generally gets what he does by a gesture of humanitarianism, which is a late development in the social evolution of man.

In all communities, three structural agencies are present: the home, school, and church. Even though they fall short of doing their share in preparing the children of these rural communities for a more positive participation in the advancement of worth while American life, we must look to them for the solution of many of these problems. In the homes, the parents are frequently more ignorant along lines of

health than the children whom they should guide. In the church, the leadership is frequently untrained, or so much obsessed with fanatic denominationalism that little thought is given to the local problems of hygiene and sanitation and their effects on the normal growth and development of the children. Of all the agencies, the rural school teacher, although underpaid and poorly trained, seems to be the key to the solution for the present.

SUGGESTIONS FOR PRACTICAL IMPROVEMENTS

Specially trained teachers with some originality, flexible enough to make an adjustment and dynamic enough to initiate and supervise community health projects, could correct most of the conditions listed. This "key" person should be well paid and encouraged to stay in a county and work on the problems at hand with some assurance that his efforts will be repaid with sufficient compensation and security. The public health nurse, who is the backbone of any rural public health program, should be closely associated with this "key" person in the school so that small health projects may be integrated into the activities of the schools. Under the supervision and advice of the state and county boards of health and education offices, the teacher, the nurse, and the county farm agent could eradicate in a few years many of the factors responsible for the conditions mentioned.

Diversified farming should take the lead, and there should be a well integrated and not too radical program of information concerning venereal disease control. When dealing with ignorant people of many years of prudery and with unintelligent church officials, extreme tact is necessary in order to get their coöperation in the control of

a disease the solution of which they have preached only morality. The screening of the home, and the building and use of sanitary privies should be a part of the community projects. The teacher and others associated with him in this project can do much to set examples by proper sanitation of the school building and grounds, urging more sanitary methods of handling food and drinking water, and the washing of hands after going to the toilet. The young people will take these practices back to their homes, observe them at picnics, churches, and festivities, and thus influence the community in which they live. There is a great need for leadership of an intelligent character.

SUMMARY

According to recent surveys made in Bullock County, Ala., and Tallahatchie County, Miss., the most common finding in Negro children in rural districts in the South is anemia. This anemia is sufficient to interfere with the normal growth and development, and is due in general to either a dietary inadequacy or to the effects of the three important types of infection; namely, syphilis, malaria, and hookworm. The chief factors responsible for these conditions are ignorance and poverty. These can best be corrected under the present set-up by the use of an efficient local school teacher as the "key" person under the supervision of the official agencies, and with the coöperation of the public health nurse and the farm demonstration agent.

A Critical Discussion of Some Methods and Standards for Certified Milk*

J. HOWARD BROWN, PH.D.

Department of Pathology and Bacteriology, Johns Hopkins University, Baltimore, Md.; Chairman of the Committee on Methods and Standards of the American Association of Medical Milk Commissions

IN the title of this paper, the word critical is used in its classical sense, meaning an analytical or judicial discussion, a critique. The discussion is confined to *some* of the methods and standards for the production of certified milk which in some respects may be at variance with the thought, organization, and administrative procedure of health departments and the standard methods employed in most milk control laboratories. I hope to show the reasons for regarding the supervision of certified milk production as a special problem requiring special methods and standards. In doing so, I shall discuss (1) certain features of medical milk commission control, (2) the bacteriological methods and standards for certified milk, and (3) pasteurization of certified milk.

There is not sufficient time to go into the details of stable practice, care of equipment, construction of buildings and equipment, etc., important as are some of these details. However, it is a fact, as you know, that a conscientious, capable dairyman may produce a good product with rather simple equipment and in rather unattractive surround-

ings; whereas, with a fine herd, excellent equipment, and attractive surroundings, an unreliable, slipshod or incapable dairyman may produce a poor product. The safety and quality of the milk are the objectives; the other factors are means to this end. I would, therefore, rate the qualifications of the dairyman as of chief importance in the production of certified milk.

The Medical Milk Commission is usually appointed by a state, county, or city medical society. It has no official standing except such as may be recognized in the community which it serves. Because of its unofficial standing, the commission enjoys the privilege of private contract. It may and does refuse to enter into a contract with a dairyman whom it regards as lacking "proper interest and intentions" even though he may have suitable livestock and equipment for the production of certified milk. It would be more difficult for public health officials to take this attitude. Composed, as it is, mostly of physicians, the medical milk commission is particularly well qualified to exercise medical supervision of dairy employees which it does by providing a Commission physician who visits the certified milk farm each week, more often if necessary, and who subjects every new employee to a thorough

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

medical examination before he is allowed to begin work, and periodically thereafter. It is hardly reasonable to expect a health department to render this service to such a small minority of producers as are engaged in the production of certified milk.

The bacteriological standards for certified milk require that it "shall contain not more than 10,000 bacteria per c.c." when delivered to the consumer and that certified milk-pasteurized shall contain "not more than 500 bacteria per c.c.," as determined by plate counts in a special agar, referred to as A.A. M.M.C. agar, which has been found to yield considerably higher counts than does the standard nutrient agar of the A.P.H.A., counts of the same magnitude as may be obtained with the "tryptone glucose skim milk agar" recently advocated by Breed and his associates. The improved medium not only gives a bacterial count that is more nearly true but its adoption serves, in effect, to raise the standard for certified milk.

During the first year of its use the Committee on Methods and Standards of the American Association of Medical Milk Commissions has compiled data, involving over 1,300 milk samples, from laboratories in 25 cities using this medium. These results are presented in Chart I. In this chart it will be noted that in the improved agar 91 per cent of the samples of unpasteurized certified milk had counts below 10,000 per c.c. We may call this a "compliance rating of 91 per cent." The compliance rating for certified milk-pasteurized, with a required maximum count of 500 per c.c., was 80 per cent. It is obviously impossible to compute a compliance rating for counts of other grades of milk since the legal requirements differ in various localities; but if we should assume a legal maximum count of 30,000 per c.c., the compliance rating of other grades of pasteurized or raw milk would be 80 per cent, and in order to have a rating of 91 per cent, the legal requirement would have to be

CHART I
Comparative Plate Counts of All Milk Samples in A.A.M.M.C. Agar

TABLE I

Comparison of Plate Counts of Milk from Two Different Producers.

<i>Milk 1</i>		<i>Milk 2</i>	
	600		4,000
	50,000		7,000
	1,500		5,000
	2,000		4,500
	100,000		8,000
	8,000		5,500
	4,000		3,800
	6,000		3,500
	500		6,000
	13,000		5,250
<hr/>		<hr/>	
Log. Average	5,070	Log. Average	5,080
Arith. Average	18,560	Arith. Average	5,255
Uniformity Rating	27%	Uniformity Rating	96%

If the standard for the above milks was 10,000 colonies per c.c., Milk 1 would have a Compliance Rating of 70% and Milk 2, 100%.

70,000 per c.c. The arithmetical average of the samples of unpasteurized certified milk was 5,262 per c.c. The logarithmic average was 3,425 per c.c. The judging of milk by averages is not recognized by the Methods and Standards for Certified Milk since it is required that the milk shall be of uniformly low count rather than of average low count. However, by computing a ratio between the logarithmic average and the arithmetical average, one may obtain a "uniformity rating" of the product. This may be illustrated by the examples given in Table I. The logarithmic average of the two milks are approximately the same although the arithmetical average of Milk 1 is more than three times that of Milk 2. If we had a perfectly uniform milk the logarithmic average would be the same as the arithmetical average and the uniformity rating would be 1.0. In my estimation, the logarithmic average serves too effectively to minimize and conceal the faults of Milk 1. On the other hand, it is the opinion of some that the arithmetical average imposes undue penalties for occasional high counts.

I am aware that there is a growing tendency in milk control work not to publicize actual milk counts or averages. However, if the uniformity ratings and the compliance ratings of these milks are compared, a fairly accurate idea of their bacteriological quality is obtained provided the basis of the compliance rating is known. Computed by this method, the uniformity rating of the samples of certified milk-raw, shown in Chart I is 66 per cent; that of certified milk-pasteurized, 58 per cent; other grades of pasteurized milk, 31 per cent; other grades of raw milk, 25 per cent. With a knowledge of the required bacterial count, the compliance rating, and the uniformity rating, one obtains more nearly complete information of the bacteriological quality of the milk than is revealed by either the arithmetical or the logarithmic average. The reductase test is not suitable for milk of low bacterial count.

The Methods and Standards require that certified milk-raw "shall contain fewer than 10 organisms of the coli group (*Escherichia* or *Aerobacter*) per c.c. of milk" and state that "properly pasteurized milk should contain no

problem. All milk should not be regarded simply as "raw" or "pasteurized." Even though the volume of certified milk may be relatively small, it is worth while to have in any community a product which shows how good milk can be. Such a product should be used to exert an influence on the entire industry and to strengthen the hands of milk control officials. The Methods and Standards for the Production of Certified Milk are to be "regarded as minimal" and may be

augmented by local requirements. If, at any time, a certified milk is regarded as below standard, health authorities should report it to the American Association of Medical Milk Commissions, Inc., 1265 Broadway, New York, N. Y. Certified Milk should be a coöperative enterprise among producers, milk commissions, and health authorities.

Rheumatism

IN recent years we have almost removed from the list of killing diseases enteric fever and smallpox, and the rôle of Public Enemy No. 1 seems now to be given properly to rheumatism—to which at least one-sixth of our expenditure under National Health Insurance is attributable.

Fortunately the study of rheumatism is becoming accepted as a

world problem, and the obscure origin of this disease is being gradually clarified—though we are not yet able to explain such problems as why rheumatoid arthritis afflicts six times as many women as men between the ages of 25 and 34.—Presidential Address, Blackpool Congress, May, 1938. *J. Roy. Inst. Pub. Health & Hyg.*, July, 1938.

that it shall be pasteurized and bottled on the farm where it is produced and that the pasteurizing equipment shall not be used for the pasteurization of any other grade of milk. Since these requirements may appear to be at variance with public health regulations for the pasteurization of other grades of milk, I wish to present the reasons for them, from the viewpoint of the American Association of Medical Milk Commissions.

It is regarded as necessary not only to maintain the identity of certified milk as distinguished from other grades of milk but to maintain the identity of the milk from each individual farm. This would be found to be of enormous public health value if pathogenic organisms should gain entrance to a certified milk supply. Not only would it limit the spread of an epidemic but it would enable the public health officials to trace the source of the epidemic almost immediately. It is desirable to fix the responsibility for the safety and quality of every bottle of certified milk onto the individual producer rather than to divide this responsibility with pasteurizing and bottling plants within the city. It is not desirable that certified milk bottle caps should be available in plants where other grades of milk are bottled.

Certified milk should not be pasteurized and bottled with equipment used for any other grade of milk. Even though it may be proposed to pasteurize certified milk in clean, sterilized equipment ahead of any other milk that is to be pasteurized, it is doubtful whether this equipment can be guaranteed to be perfectly sterilized every day. It is true that it may be sterilized just as well as the equipment on the certified milk farm, but it must be considered that equipment on a certified milk farm is used for no other grade of milk at any time and that other grades of raw milk are not safe as is indicated by the occurrence of over 380 epidemics traced

to such milk during the past 10 years, whereas only 17 were traced to supposedly pasteurized milk, and none to certified milk. Many of the producers of certified milk are relatively small producers shipping small amounts of milk to a number of distributing points. It is doubtful whether the large city pasteurizing and bottling plant would find it convenient or profitable to postpone the pasteurization of the large volume of other grades of milk until the small volume of certified milk had been run through the equipment. What might happen if the arrival of the certified milk were delayed?

It is contended that regulations, such as pasteurization within the city, desirable for other grades of mixed milk, would tend to lessen the safety and lose the identity of certified milk which there is every reason to believe is a safe milk before it is pasteurized. Certified milk-pasteurized is required to be certified milk before it is pasteurized. Unfortunately, the effort to maintain it so is more difficult in those communities which have sought to improve the milk supply by requiring that all milk, including certified, shall be pasteurized. Referring back to Chart I, it is noted that the compliance rating of the samples of certified milk-pasteurized examined was 80 per cent. It is rather suggestive to note that all but one of the samples with counts above 500 per c.c. were reported from communities where all milk is required to be pasteurized, and, referring to Chart II, that all of the samples containing coli group organisms were also from such communities. It is feared that the knowledge that all the milk is to be pasteurized leads to lack of interest in clean safe milk production. The best certified milk-pasteurized is to be found where some of the milk is sold as certified milk-raw.

For these and other reasons certified milk should be regarded as a special

A More Effective School Health Program*

JOHN T. PHAIR, M.D., D.P.H.

Chief Medical Officer of Health for Ontario, Toronto, Ont.

SCHOOL health supervision as it exists today is a logical but inhibited outgrowth of the original effort known as school medical inspection, which was designed primarily to control contagion. The latter name still clings to it, despite the fact that in many centers, particularly in Canada, no physician is associated with the service. Its development, like other types of community welfare service, was forced, in that new fields of effort were allocated to those associated with the plan without permitting them an opportunity for the consolidation of ground already won. By this, I mean that, while a useful contribution to the control of communicable disease, particularly such contagious conditions as pediculosis, scabies, impetigo, etc., was made, the status of the original program was never more than that of a logical auxiliary to an acceptable community health service.

Imposed upon such a foundation the added responsibility entailed in the regular examination of the presumably healthy child increased the instability of this rather loosely built structure. The lack of special training and enthusiasm on the part of the staff resulted on occasion in administrative indigestion and thinly veiled conflict with the parties most concerned in mat-

ters affecting the health of children, namely, the parents and the medical profession. The program has also possibly suffered from the attitude of some of those propagandists who sponsored its adoption during the days of its rapid extension on this continent. Convinced of its merit, in their desire to impress municipal and school authorities with its value, they implied finality as to procedure and exaggerated its potentialities.

Referring briefly to its original accomplishments in the field of communicable disease control, we are inclined to wonder just what were the conditions which made possible so much in the way of achievement, having in mind the limited qualifications of the staff and the methods adopted. Actually, much of the success attained was due to the failure on the part of both the public and the medical profession to manifest any serious concern with the official requirements in the matter of controlling the spread of contagion. These were the days when the interest of the family physician in this field was confined to the reporting of small-pox and diphtheria and when absence from school for scabies or ringworm might, if there was no parental concern for the education of the affected offspring, extend to the best part of the school term.

Criticism has been leveled at the methods designed to achieve the first of the commonly recited objectives.

* Read before the CEM Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

In the early days of the service when all of the emphasis was placed on the control of communicable disease, the accepted procedure was to have all children showing evidence of suspected contagion referred to the school physician, who visited each school in his district daily. Those who were unable to present a convincing excuse for absence were also likely to be included in this group. When the nurse became an accepted member of the staff, routine classroom inspection was added to the list of endorsed procedures. Then followed the post-holiday rapid inspection and the special daily review of affected classrooms or schools when certain diseases were epidemic in the community. Home visiting by the nurse and physician of suspected absentees was at first a fruitful source of investigation. In an effort to insure the interest of teachers, the daily readmission of all returning absentees was ultimately resorted to. Children who had been absent for a minimum of 2 days were sent to the appropriate office upon the arrival of the school nurse or physician. The fact that all too often they had been allowed to mingle freely for from 1 to 3 hours with the other pupils in the classroom was condoned when it could not be controlled.

Sound, statistical support on behalf of this branch of the service is not readily obtained; neither is it possible to refute statistically its value. Going over old reports I find reference to the statement that 40-50 per cent of the cases of communicable disease reported in certain urban centers were reported by the school health staff and that many of these cases were found in the classroom. Presuming this to be an approximation of what may have been true, and comparing it with figures for the Province of Ontario, we find that the percentage has fallen to the point where one might be justified in ques-

tioning the necessity for continuing to include this field of effort among the objectives of the service. The same records would appear to imply that the more effective the municipal health organization, the smaller was the percentage of pupils found in school with evidence of communicable illness. Despite the previously referred to implication, however, there is evidence to show that the control of communicable disease still has a place among the objectives set by the advocates of school health supervision.

While one may comment critically on the methods designed to limit the spread of contagious illness, the substantial contribution made by the school authorities to the success of our efforts at active immunization should not go unnoticed. The aid extended, either directly or indirectly, to the health authorities in this constructive effort, has made possible much of the success achieved. Further, the fact that public opinion has been favorably influenced on behalf of such control measures as are effective, must also be added to the non-tangible good which has resulted from this service.

But let us pursue our review of the objectives and their approximation:

Prior to the time when the responsibility for insuring the discovery and correction of present and potential defects was assumed by the school health staff, the program had been rather hesitatingly accepted by the community. It was apparently considered as a service more or less complementary to that carried on by those official agencies which had previously preempted the prerogatives of the public in the matter of the control of communicable forms of illness. Now with this added function, it took on an aspect of municipal paternalism which presumed further to abrogate from the parent the formerly accepted privilege of deciding as to the health needs of his offspring. This

second objective further appeared to be a subtle invasion of the prescribed field heretofore allocated to the family physician. In view of this fact, there was no avid acceptance of the service by either the profession or the public. Even the interested parent was at first lacking in enthusiasm for such a program.

The original presumption that parents would welcome the opportunity of being informed as to the health needs of their children, and following the receipt of such information would take the necessary steps to insure prompt correction of unsatisfactory conditions reported, was found to be applicable to only a limited number, variously estimated as being between 25 and 40 per cent.

The method of examination originally adopted was not designed to placate either parental or professional prejudice and the service suffered some loss of prestige, if it ever had any to lose. The continued questioning of the judgment of the school medical officer by both parent and practitioner led to some modification of the rather casual type of examination originally in effect. That these modifications have not always accomplished the hoped-for result is evident to anyone who carefully reviews the data of some well recorded service.

There have been a variety of methods adopted since the day of the rapid mass examination. In some centers, the examination is as complete as it is possible to make it, with the parent invited to be present; in others, the examination lacks only the presence of the parent. Again, in others, a team of physicians with special qualifications carry out the actual examination after the children have been screened by a nurse or teacher. Again, in some communities, the entire program is in the hands of nurses, supposedly carefully chosen and specially trained for such

service. The variety in method also extends on occasion to the number of examinations to which the child is asked to submit and the stage in his school career in which the examination is to be carried out. In some centers, he is examined on admission and again prior to graduation; in some instances, 3 examinations are made in the school life of the child; while in others, the responsible authorities have been influenced by the advocates of periodic physical examination to the point where they have adopted the plan of annually examining the school population.

It is not my thought that this diversity of method should be considered critically or to imply confusion where none exists, for I realize fully the difficulties which have periodically confronted those responsible for the establishment and conduct of this essential service. I wish merely to say that this multiplicity of method has added to the perplexities of those anxious to insure the extension of school health supervision.

The further expansion of the original program to include a directional interest in all matters pertaining either directly or indirectly to the present or future well-being of the school age child, which objective included in some centers the conduct by the health personnel of the health teaching program, added nothing to the list of supporters of the service. Neither did it tend to lessen the confusion inherent in such a state of affairs, for here we have a service being compelled to expand its program without the opportunity to "mop up" as it went along. To its own critics, and no one has been more critical of its limitations than those engaged administratively in its conduct, two shortcomings stand out:

First, the fact that we have been unable to secure from organized medicine the recognition that the service

justly warrants. This failure can be rightly laid to our own unwillingness to find the proper place for the general practitioner as a co-partner in the scheme. Second, our evident inability to obtain the appropriate correction for physical defects found or suspected.

While the second of these shortcomings looms superficially as the more significant, the first probably in any critical analysis of cause and effect would be considered the more important. However, our concern at the moment is our inability to demonstrate in a tangible fashion the result of our efforts. Innumerable children are found with evidence of some of the commoner physical defects; the parents are informed of the presence of such defects and yet correction is perennially procrastinated or the recommendation flatly ignored.

We have already referred to the apparent unsoundness of the original premise upon which the service was established, namely, that all parents are sufficiently interested in the physical status of their children to accept readily the suggestion that professional advice and treatment are essential. Whether the statistical evidence warrants us in an acceptance of the presumption that the previously mentioned failure to seek medical advice following the receipt of the generously distributed notification of defect is due to lack of interest, whether it is due to some defence reaction, or whether there is some other more acceptable explanation for the condition noted, is to my mind a problem, the solution of which might well be left to the psychologist experienced in evaluating motivating influences. I might add here, however, that while the inability of the family to pay for treatment is a valid reason in a percentage of cases, the number who give this as a justification for inaction is not, on careful inquiry, so great as some of you may presume.

The challenging fact which confronts those of us who are permitted an opportunity to review our service in terms of its accomplishments and limitations is that only 30-40 per cent of conditions (other than dental defects) stated by the school physician to warrant treatment, receive such treatment within 2 years of their discovery. May I state here that I am fully appreciative of the excellent work done by the New York Study Group in the inquiry into the factors influencing this condition, and urge that the findings of the group be carefully reviewed in terms of their possible application to your local problem.*

Without any further assumption of the magisterial prerogative of being wise in retrospect, I wish to record for your critical comment a suggested modification of the plan which has been for many years in effect in the majority of those centers in Ontario in which a physician is associated with the service. In evolving this scheme, we have kept in mind the following presumptive premises, both of which have been referred to in the rather protracted preface, namely, that our failure to include the family physician in our program has contributed definitely to the limitations of our achievement, and that some of our difficulty is due to our evident unwillingness to limit the term "notifiable defect" to those physical or mental abnormalities, the patency of which is such that even the most unconcerned physician is likely to subscribe to their significance.

We suggest that the school health program make provision for the early examination of all beginners; that this examination be as thorough as it is possible to make it, preferably with the parent present; that following examination, the child be placed in one of

* *Physical Defects—The Pathway to Correction*, 1934. Obtainable from A.P.H.A. Book Service.

three categories, labelled for convenience, groups A, B, and C. Group A to include all children found to be presumably well; group B to include those children who, in the estimation of the examiner show some signs of below normal well-being but not displaying an evident physical defect; group C to include all children requiring early medical advice or treatment. The child placed in Group A, as an individual ceases to be a concern of the school medical officer as long as he remains in this category. He would, however, automatically drop into Group B following his having suffered from any accepted type of acute illness. He would then appear at a convenient time for reexamination by the physician and his category would be subject to revision.

In the event of the child being placed in group B, the assistance of nurse and teacher is sought in an effort to uncover information which might supplement the findings of the examining medical officer. Such information might rightly include the child's dietary and other health habits; his reaction toward work and play; the scope of his extra-curricular activities; and the extent and considered seriousness of those previous illnesses reported by the parent at the time of examination.

In order to avoid confusion, it is recommended that the length of the period of observation be fixed, say at 3 months, and that the physician note on a suitable form, for the guidance of the nurse, those particular points in respect to which he wishes added information.

The nurse is expected to see that the child presents himself for reexamination at the expiration of the period of observation; at which time, in the light of the knowledge already on hand and the additional information secured, a further attempt is made to estimate the present or future physical status

of the child. He might rightly be continued for a further fixed period of observation in group B; placed in group C; or now stated to belong in group A.

Some such procedure as the above should lessen the possibility of the school health staff committing itself to a premature diagnosis, and places the physician in a more acceptable position in the event of the family practitioner disagreeing as to the clinical accuracy of his findings and recommendations. Further, during the period of observation, the nursing staff is permitted an opportunity to create interest where necessary, in both parent and teacher, in the health of the individual child.

Criticism is levelled at the practicability of any plan of informing the family physician of the school medical officer's findings, without resorting to the dubious method of sending it through the child or parent. Despite such criticism, I do not believe that we should ignore the desirability of establishing an ethical contact between the school health staff and the physician; such contact to be comparable to that associated with our other professional relations with our fellow practitioners. While it is accepted that there are a considerable number of families in any community with no fixed affiliation with any physician, I do not believe that the number of these having children of school age is as large as has been estimated; probably not more than 20-25 per cent are in this class. Those in the lower wage earning group, who will be more than likely dependent for any necessary treatment on the clinic facilities of the community, might rightly be excepted. Granted that this number might even be higher than suggested, I still believe that much good would result from a serious attempt to inform the physician directly of the school physician's findings and

recommendations, since he is the agency responsible for the suggested treatment. It is therefore urged that the school medical officer, at the time of examination—using an acceptable type of form—tell the physician who has been named by the family as the doctor of their choice, exactly what he has found and the implications which he has drawn from such findings. This statement should be mailed promptly and should be as personal as is possible to make it. In those cases in which the child has been under observation and this fact recorded, the position of the school medical officer is materially strengthened. Not only should such a practice encourage more accurate deductions from physical findings by the school medical officer, but it should go a long way to eliminate any feeling of professional irritation upon the part of the general practitioner. Certainly the physician who has before him an intelligent statement from a medical confrere is not likely to find himself in a position of embarrassment, when a parent, having accepted the suggestions of the school medical officer, presents himself or herself at his office with the child concerned.

The physician, following the receipt of the school medical officer's report, may adopt one of three attitudes: he may be sufficiently close to the family to justify his contacting them in respect to the matter without delay; or his relationship may not be sufficiently well established to permit him to do more than wait in anticipation of the parent's acceptance of the advice offered by the school medical officer; or he may ignore the communication entirely. Irrespective of which of these attitudes he adopts, certainly those responsible for the administration of this municipally subsidized service will have the added satisfaction of having offered this tangible evidence

of a desire to coöperate with those of the profession who are engaged largely in the therapeutic side of medicine.

Reference has already been made to the diversity of methods adopted in the matter of so called "follow up." I am strongly of the opinion that in many instances our efforts have been psychologically unsound. In many centers in Ontario, the common practice is to permit the parent who does not proceed at once to implement the school physician's recommendations, a limited period of time in which to initiate treatment. Following the lapse of this period, the nurse is asked to visit the home and, further, encouraged to continue these visits until either the parent or nurse becomes discouraged. The result of this practice is that the parent, caught by the representative of an official agency in this suggested dereliction of his or her duty, develops an attitude of non-coöperation or open resistance to our persuasive efforts and the end we seek becomes unattainable through much striving. It is recommended, therefore, that after an appropriate interval has elapsed, the parent be sent through the mail a tactfully worded communication drawing his or her attention to the desirability of accepting the advice offered at the time of the original communication; and that these letters be regularly forwarded until some concrete evidence of parental interest is exhibited; that there be no direct contact between the parent and the school health staff unless such contact is sought by the parent, until this more indirect method of approach has been found ineffective.

While none of these suggestions may be convincing, either in terms of their originality or their practicability, I do ask that they receive such consideration as they would appear to merit, in that they are brought forward after many years of experience with the procedures usually prescribed.

Cultural Methods for the Detection of Typhoid Carriers*

ELIZABETH J. COPE AND JOSEPH A. KASPER, M.D.

Department of Health, Detroit, Mich.

IN communities where the sanitation is admirable and the food and water supplies receive the fullest attention of the health authorities, typhoid fever continues to be a menace. Although residents of well protected urban centers occasionally contract this disease in some remote rural region, there are sporadic cases and occasional outbreaks which cannot be attributed to such outside sources. They are of endogenous origin, in most instances traceable to undetected carriers, who are the principal obstacles to the complete control of typhoid fever within the community. Their detection requires the constant vigilance of the epidemiologist, who must receive efficient aid from the laboratory.

There has been a long felt need in public health laboratories of a method or procedure which would facilitate the isolation of the typhoid-dysentery group from feces. A medium that would inhibit the growth of the coliform bacteria while permitting the development of the colonies of the typhoid bacilli would be a distinct contribution.

Approximately 18 months ago, our attention was drawn to a dehydrated medium which seemed to possess cer-

tain impressive qualities, the Wilson and Blair¹ bismuth sulphite agar, slightly modified by the Difco Laboratories. This medium, when ready for use, consists of:

	<i>Per cent</i>
Peptone	1.0
Beef Extract	0.5
Dextrose	0.5
Disodium phosphate	0.1
Ferrous sulphate	0.03
Bismuth sulphite indicator	0.8
Brilliant Green	0.0025
Agar	2.0

Growth of colon bacilli is greatly inhibited by bismuth sulphite agar but it is doubtful that they are killed, since it has been possible to obtain growth after transplanting to other media. The inhibition of the colon bacilli allows the typhoid colonies to make their appearance without hindrance. Such colonies are black and flat and, when typical, surrounded by zones of a glistening metallic character confined to the surface of the medium. Although good colonies may be observed after incubation for 24 hours, their appearance is most typical after 48 hours.

The first attempt to evaluate the merits of the bismuth sulphite agar as a medium to be used routinely was made by planting the fecal specimen on Endo agar and on the bismuth agar simultaneously. Cultures on both

* Read before the Laboratory Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 8, 1937.

were made by streaking out loopful amounts of the fecal emulsion on the respective plates. The emulsion was prepared by mixing approximately 5 gm. of the feces with 10 c.c. of physiological salt solution, allowing it to stand for about 1 hour and using the supernatant portion for planting.

In this first comparison, 100 consecutive cultures were made, with results almost alike; but a few discrepancies suggested that not all of the positive cultures possible were being obtained. By this method of planting, the bismuth sulphite agar was found not to be superior to the Endo agar. The colon-inhibiting property of the bismuth sulphite agar was so striking that work was carried on, streaking bismuth medium with the feces directly, while the Endo agar continued to be streaked in the usual manner. By this method, the bismuth agar was found to be approximately 16 per cent more efficient than the Endo agar as judged by the increased number of positive cultures that resulted.

Believing that this increased efficiency of the bismuth sulphite agar was to be accounted for by the use of the more concentrated fecal substance for the cultures, another series of observations was made, which forms the basis of our present report. Three procedures were followed in planting the fecal material of each specimen. Each culture consisted of 3 plates. Endo agar was streaked with a loopful of the fecal emulsion, a bismuth sulphite agar plate was smeared with undiluted feces by means of a cotton swab, and the third plate was prepared by pouring 15 c.c. of the melted bismuth sulphite agar at about 40° C. over 5 c.c. of the fecal emulsion. All plates were examined for typical colonies after 24 hours, which were then transplanted to Krumwiede's triple sugar agar. The bismuth sulphite agar plates were incubated for an addi-

tional 24 hours if no colonies were visible at the end of the first incubation. Whenever the triple sugar reactions were in support of the typhoid-dysentery group, suspensions of the organisms were examined for motility. The final step for establishing the identity of the isolated organisms was agglutination with typhoid and paratyphoid antisera. Only dilutions in titers above 1 to 300 were considered diagnostic. However, most of the reactions were positive in dilutions of 1 to 1,000.

The manner of evaluating the 3 procedures is illustrated in Figure 1. Each symbol is composed of letters appearing in the names arbitrarily chosen for respective procedures, as: E = Endo agar, S = bismuth sulphite agar streaked with feces, P = bismuth sulphite agar poured over emulsion, etc.

In 1 year, the laboratory of the Detroit Department of Health received 2,273 specimens to be examined for the presence of intestinal pathogens, of which 64 were urine, and 2,209 feces. Each specimen was classified according to its source and was listed as coming from a case, a contact, or from a food handler. In the group from cases are included those submitted for diagnosis as well as those for release from hospital or home. In several instances, the case release cultures numbered 20 or more, while the average number of cultures examined for cases was 8. The specimens from contacts were received largely on the advice of the epidemiologist to determine if passive carriers were present in the homes of those suffering from an acute intestinal disease. Occasionally a chronic carrier was discovered by this procedure. Listed as food handlers are those persons who, upon epidemiological investigation prior to receiving permission to engage in the preparation or distribution of food for public consumption,

were suspected of being chronic carriers because of a history of enteric infection.

Table I is a summary of the number of specimens examined for organisms of the typhoid-dysentery group—the total number positive applies only to the finding of typhoid or paratyphoid bacilli. Dysentery bacilli were not considered for purposes of this comparison. Of the 452 positive cultures, 5 showed the presence of *Salmonella schottmülleri*, 2 were positive for *Salmonella paratyphi*; and 2 for both *Salmonella schottmülleri* and *Salmonella paratyphi*. Reference is also made to initial positive cultures, a group compiled on the basis of the examination made of each person's specimen received for the first time, irrespective of the number of subsequent examinations that were made. The total of 107 of such specimens is an index to the number of car-

riers of the typhoid bacilli according to class. It may be roughly estimated that in Detroit during this study there were 25 cases; 58 contact carriers, either active or passive; 24 carriers who, because of their occupations, would endanger the health of some persons if they were not detected by laboratory means.

The total and initial positive cul-

						52.8%	47.1%				

tures in Table I are again found in Tables II and III. It will be seen that approximately 40 per cent of the positive findings would not have become available had sole reliance been placed on Endo agar for the isolation of the typhoid-paratyphoid organisms, though approximately 20 per cent of the positive cultures were obtained through this medium alone.

While bismuth sulphite agar is a valuable adjunct to Endo agar as a means of isolating a greater number of intestinal pathogens from feces examined routinely, it cannot entirely replace the latter. Moreover, Endo agar in expert hands may be successfully used for the isolation of the dysentery group of organisms that will not be revealed on bismuth sulphite media.

The value of a differential-enrichment medium in the form of bismuth sulphite agar would seem to be firmly established. These results also suggest that future modifications of such media may eventually culminate in further simplifying the routine examination of feces and increase the efficiency of the laboratory as an aid to the epidemiologist in the detection of typhoid carriers.

SUMMARY

An analysis of the merits of the Wil-

son and Blair bismuth sulphite agar, slightly modified, as compared with those of Endo agar for the isolation of intestinal pathogens is based on a total of 2,273 examinations of feces and urine.

In the finding of 452 positive cultures, the bismuth sulphite agar, when poured over 5 c.c. of a heavy fecal emulsion, accounted for an increase of approximately 40 per cent of the positive cultures.

Endo agar accounted for the recovery of typhoid and paratyphoid bacilli from 23 per cent of the number of positive specimens when bismuth sulphite agar failed.

In view of the positive findings obtained by means of the Endo agar alone, it is inadvisable at present to discontinue its use in favor of any recently developed differential plate medium.

A useful purpose will be served by supplementing the use of Endo agar with a differential plate medium such as bismuth sulphite agar for the routine examination of fecal specimens.

Present Status of Vitamin Milks*

E. V. McCOLLUM, PH.D., F.A.P.H.A.

*Professor of Bio-Chemistry, School of Hygiene and Public Health,
Johns Hopkins University, Baltimore, Md.*

THE discovery, in 1922, that rickets in infants and children is caused by deficiency of a specific dietary factor, now known as vitamin D, opened the way to a program of prophylaxis against this disease. The results already obtained, show that the prevention of rickets can be realized, and that this is one of the outstanding achievements in the field of preventive medicine. In temperate regions, the prevention of rickets through the agency of sunlight is not possible of realization. The methods available are: (1) the administration of suitable doses at regular intervals, at least during the colder months, of some one of the fish liver oils which are available; (2) the distribution of concentrates of fish liver oils containing vitamin D; (3) the distribution of viosterol, a product consisting of vitamin D derived from irradiated ergosterol, of yeast; (4) the irradiation of certain commonly used foods; (5) the feeding of irradiated yeast to cows, which then yield milk containing an effective content of vitamin D; (6) the fortification of some commonly used foods with a concentrated source of vitamin D; and (7) the general employment of ultra-violet lamps for irradiating the skin.

The vitaminization of milk, the food most constantly consumed by infants and children, is the method of choice in prophylaxis against rickets. It is the simplest, safest, and most economical way of getting the desired results. The experience of several years leaves no reason to doubt that vitamin D milks have come to stay, and that their distribution will increase.

The question has naturally been asked by many people: Are we liable to get too much vitamin D? *The Journal of the American Medical Association*, commenting on this editorially in 1931, said: "There is evidently an enormous range of safety between prophylactic or therapeutic dosage and the quantities that are likely to do harm. The toxic dose is probably 1,000 times the therapeutic dose of viosterol." The same Journal has also given editorial approval of irradiated milk and milk derived from yeast-fed cows. Up to the present, the latter procedure has been used only by the certified milk industry. It is clear that any of the methods enumerated provide safe and effective sources of the antirachitic vitamin. An important fact is that pasteurization or boiling does not depreciate the value of vitamin D milks. The approved content of added vitamin D in milks for prophylactic purposes is about 400 International Units per quart. This is approximately one-third the commonly

*Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

used dosage for therapeutic purposes. Vitaminization of milk by any of the methods which are practicable has the advantage over other sources of vitamin D, that the active principle is made available in a highly palatable form. This is especially important to adults who are frequently averse to taking fish liver oils.

There are now scores of reports by clinicians setting forth the effectiveness of the vitamin D milks for prophylaxis against rickets. Opinion seems to be unanimous that the general provision of vitaminized milks is the method of choice. That such milks will have a field of usefulness in dietotherapy in certain diseases affecting adults is equally certain. This view is supported by the considerable number of reports of their use in the treatment of tuberculosis, in the treatment of fractures, in the prevention of tooth decay, in the treatment of trichinosis, in arthritis, and in the improvement of the general health. These milks should be very useful in safeguarding the health of pregnant and lactating women. Bunker and Harris have recently given a comprehensive discussion of the clinical status of vitamin D milks.

Since the vitamin D potency of milk can be determined only through a biological test or bioassay, it is necessary that health officials require such assays at suitable intervals, and that these shall be made by well equipped laboratories. This method is somewhat time consuming and expensive, but it is not necessary that assays be made oftener than once in a few months, provided samples are taken by officials at any time, and without the knowledge of the distributor. This knowledge will keep him on the alert, and insure proper coöperation with health officials in safeguarding the quality of the milks.

The employment of vitamin D con-

centrates made from fish oils insures not only the fortification of milk with vitamin D, but also increases significantly the amount of vitamin A which it will contain. Fortification with viosterol, provides vitamin D only. The same is true of irradiated milk.

After several years of constantly increasing distribution of vitamin D milks, and of extensive discussion of their use by physicians, there is scarcely a dissenting voice from the profession as to the desirability of their use in safeguarding the health of infants and children. Although less often mentioned, it seems clear that the pregnant and lactating woman stands in as great need of additional vitamin D, over that which she secures in eggs—the only food which is commonly eaten which contains appreciable amounts of this substance—as does the infant or child. The palatability of vitamin D milks makes them especially appropriate as a source of this nutrient for women, who generally dislike fish liver oils.

There has been some consideration of the desirability of adding to milk either vitamin C (ascorbic acid) or vitamin B₁, both of which are now available in the form of synthetic products identical with the naturally occurring vitamins.

Freshly drawn milk contains about 22 mg. of ascorbic acid per quart. The content steadily falls off under ordinary methods of handling, even before pasteurization, and the latter treatment destroys practically all of it. The cost of adding sufficient ascorbic acid to milk to make it serve as a safeguard against scurvy, is not prohibitive at present, and may be lowered in the future. The fact that citrous fruit juices are generally available for infants and children, and that raw fruits and vegetables generally are good sources of ascorbic acid, makes it less imperative that milk be forti-

fied with this nutrient than is the case with vitamin D, which is not available in sufficient amount in any of our natural foods. It is not likely that the medical profession will become very enthusiastic about the addition of ascorbic acid to milk for this reason.

As respecting the fortification of milks with the antineuritic vitamin B₁, one may say that there is some prospect that the pediatrician may see advantages in having such milks available, both for infants and for pregnant and lactating women. There is considerable evidence that many people are getting less than the optimal amount of B₁, because their diets are not of suitably high quality. Since the synthetic vitamin is now available in abundance, it is to be expected that the time is not far distant when sufficient clinical observations from its administration will become available to serve as a basis for judgment on this point. The wisdom of providing B₁ fortified milks must await the initiative of the medical profession. It is yet too soon to make any recommendation relative to this matter.

Regarding vitamin A, it is interesting to note that a number of studies

have shown that the new-born have almost no store of this substance, which is extremely important for the health of the epithelial structures. Colostrum is several times richer in vitamin A than is milk, and it seems extremely important that the very young should be fed this vitamin liberally for a time in order to fill up their livers with it. It has been shown that pups require several weeks of suckling in order to raise the content of vitamin A to half the content of the livers of their mothers. For this reason, it would seem that fish liver oil concentrates are better sources of vitamins for addition to milk which is to be taken by the very young infant than are other sources of vitamin A and vitamin D.

In conclusion, it may be reiterated, that the vitaminization of milks with respect to D is of established value. Milk distributors and health officials will do well to delay offering to the public any other kinds of fortified milks until the medical profession asks for them.

Postgraduate Education of Physicians in Pediatrics*

MYRON E. WEGMAN, M.D.

*Pediatric Consultant, Maryland State Department of Health,
Baltimore, Md.*

ATTEMPTS to provide for postgraduate education of general practitioners have taken many directions. The physician in the city has available hospital clinics, lectures, and staff conferences. He usually has fairly frequent medical society meetings with speakers to cover the newest advances in the various branches of medicine. In addition he has the priceless boon of library facilities. The rural practitioner, on the other hand, unless he is particularly fortunate, has almost none of these opportunities. This deficiency has been recognized and measures have been taken to overcome it. One of the most successful has been the holding of so-called institutes where short intensive courses are given by men of ability. Such institutes, however, must be given at some central point and are intended to attract physicians from a large area. This, of course, entails the necessity of some of the men coming very long distances, and to get any real benefit from the course of lectures, they must remain away from their practices anywhere from a few days to 2 weeks. Such a course is often impracticable for many country practitioners. Although these

institutes have met with excellent response, there still remains a large group of men who are not reached by such efforts and who are entitled to consideration.

In the summer of 1936, Dr. J. H. Mason Knox, Jr., Chief of the Bureau of Child Hygiene, Maryland State Department of Health, initiated a program with regard to pediatrics, designed in part to meet the needs of this group of rural physicians, in more or less outlying areas. A full-time pediatrician was employed, who was to concentrate on one section of the state as a demonstration area.

The district chosen includes 3 counties in southern Maryland, comprising an area of approximately 1,000 square miles. The population is about 40,000 with, roughly, half of the inhabitants colored. The largest single community has a population of 700. Corn and tobacco form the chief income producing crops. A good deal of the farming is done on a tenancy basis and the general economic level is quite low. Although the infant mortality has been declining in recent years, it is still in the neighborhood of 100, with the colored mortality usually about 150 and the white about 80. Only one-third of the deaths may be ascribed to neonatal causes and diseases of early infancy.

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

There are about 25 doctors in practice, varying from 1 to 61 years in experience. Two of the counties have small, fairly well equipped hospitals. Indigent patients in need of special hospital care or clinic consultation must go to Baltimore, 60 to 120 miles distant. Venereal disease, obstetrical, mental hygiene, and orthopedic clinics are held regularly, at various intervals, in all these counties.

The program as designed was to be threefold in object: (1) to provide free consultation service in pediatrics for all patients referred by local physicians, (2) to attempt to increase the local physicians' knowledge of pediatrics, (3) to stimulate lay interest in child hygiene problems. This report will deal primarily with the second of these objects.

The method followed was worked out as follows: All the physicians in the county were interviewed individually, the consultant was introduced and the program explained. They were told that at certain times weekly, the pediatrician would be in the county health office and would be available for consultation. This could be held either in the physician's office, the patient's home, or the health office.

The reception at these first meetings varied considerably, from a hearty welcome to indifference, and in one or two cases, suspicion and skepticism.

After the preliminary meetings the schedule of visits was followed out as planned. As expected, the response was relatively meager and confined to requests from those physicians who had been most cordial. The technic followed thereafter was to make calls at random on the various practitioners and to discuss with them whatever problems might arise during the course of general conversation. By this means many of the physicians were convinced of the sincerity of intentions and honesty of motives of the State Depart-

ment of Health and the pediatric consultant. Almost invariably there would be some discussion of questions of diagnosis and treatment in pediatrics. Often before the end of such a visit the physician would recall a case in which he would like assistance and suggestions, and would make an appointment for consultation the following week. In other instances progress was not so easy and coöperation was secured only after several visits at intervals of a month or two.

It seemed clear from the outset, and the notion has been confirmed in practice, that such a program as this cannot be pushed along faster than the local conditions warrant. General practitioners who have been self-reliant and independent for many years naturally do not like to have new schemes forced upon them. One of the most coöperative physicians at present made no requests for consultation during the first 9 months.

The program as outlined has now been in effect for slightly over a year, of which a goodly part was spent in laying the foundations and securing friendship and coöperation. Evaluation of the results is by no means easy. An appreciable reduction of both sickness and deaths cannot be expected before a considerable time has elapsed. That many individual cases have benefited from the consultations was to be expected. This, of course, is a temporary affair. What has been accomplished of a lasting nature?

Of the 25 physicians in practice in the area about 75 per cent have made one or more requests for consultation. Of the 16 most active physicians only 1 has failed to avail himself of this service. About 250 consultations took place in the first 12 months, with a fairly steady but irregular increase evident. Naturally some consultations have been more fruitful than others. In general the physicians have shown

themselves very willing to accept suggestions and advice, and the resistance to new ideas has been considerably less than anticipated.

There has been no correlation between the number of years in practice and willingness of coöperation. Several of the older practitioners have made very frequent calls for the service.

The crucial test of the value of this method of bringing pediatrics to the general practitioner hinges on how much new knowledge in the field is acquired and retained. Examinations of any sort obviously are not feasible. The sole way to judge would seem to be the impressions of the consultant himself—such impressions being of naturally limited scope. One would like to have similar situations come to the attention of individual physicians so that he might note any changes in attitude or perspective which might be attributed to the influence of a previous consultation or discussion. Unfortunately such an arrangement has occurred but infrequently in the comparatively short experience we have had. Most of the practitioners in the area where this program has been carried out have been in practice for a number of years, have had to depend on themselves exclusively, and have accordingly worked out methods of treatment satisfactory to them for most of the common ailments with which they are confronted. It is asking quite a good deal to expect that they will embrace with open arms the new and often apparently revolutionary ideas of a young man, no matter how well trained. Each practitioner has first to convince himself that the pediatrician's ideas are sound and that his methods work. Nor is it of much help to find the consultant advising, as often he must, that a given case requires specialized hospital care and accordingly must be sent off to the city.

Parenthetically this is a good place to call attention to the almost uniform indifference with which many hospitals treat the busy country practitioner. The patients whom he refers to hospitals are often discharged without any notification to the physician as to further care or follow-up. A letter at the time of discharge would not only be of very great value to the physician in his handling of the individual case but would often be a material help to his understanding of the problem and his approach to similar cases in the future.

The one field in pediatrics where repetition of similar cases might be expected to be frequent and where there is considerable room for improvement is that of infant feeding. It is in this field, moreover, that the most definite evidence of benefit has been obtained. Description of simplified, rational methods of feeding has been welcomed, and such methods, once their value has been demonstrated, have been put into steady use by several of the physicians. The treatment of infantile diarrhea, one of the major causes of infant mortality in this area, has not fared quite as well although some of the physicians have now adopted present-day methods. Both in infant feeding and in the treatment of diarrhea, the consultant has been asked by some of the practitioners to prepare written outlines for their individual use. This has been accomplished with apparent good effect.

Beyond these two large groups of cases there has been a great variety of diseases upon which advice has been asked. In not a few of these the consultant has been at as much of a loss as the referring physician. In others, conditions have been recognized by the consultant and the diagnostic points made sufficiently clear so that on subsequent occasions the general practitioner has done well, unaided.

In the light of the present experience a few disadvantages of this method stand out. There is a relatively large amount of time wasted, chiefly in travel. In order to cover an area of any size and make regular visits to designated points, there are, of necessity, a good many hours spent in driving back and forth. The average weekly distance traveled by automobile has been about 500 miles. There is a further waste in the inevitable waiting around in order to fit the consultant's schedule to the schedules of the local physicians. It is obviously essential to make every effort to have the physician present during the history taking and the examination. With busy practitioners this is not easily arranged. Another disadvantage, related to the first, is the relatively small quantitative return for the investment. A much smaller audience is reached than that possible for formal lectures. In such lectures or hospital demonstrations the subject of children's diseases may be covered in its more important aspects in the space of a few weeks. Of course, such an intensive course cannot hope to clarify all the phases of children's diseases which are discussed, nor can one be sure that the individual physician carries away the important lessons. A further drawback of the present method is the inability to plan the work to cover the field of pediatrics properly, for one must take only what opportunity offers in the shape of patients for consultations.

It is hoped that, after a time, the subjects missed during consultations may be gone into in addresses before the county medical societies. Such talks would be of great help in supplementing the other work but thus far there have been only a few opportunities to make them.

On the favorable side, a few points may be made. The advantages of

having an actual case as a basis for discussion cannot be overemphasized. It is obvious, of course, that in the discussion of any case, no matter how simple, any number of problems may be brought up and gone into. When Jacobi introduced hospital bedside teaching in pediatrics in New York at the time of the Civil War, a great step forward was taken. With the impetus given by Dr. Osler, most of the medical schools in this country soon embraced bedside teaching in hospitals as a fundamental part of the course. Yet we must not forget that before the present era of highly efficient medical schools, the greater part of medical teaching consisted of an older practitioner taking the younger one around and introducing him to the "mysteries" of the art as he made his rounds from patient to patient. The loss of this experience and relationship has not been entirely replaced in our schools, and few would deny that many graduates in medicine go into practice with an inadequate knowledge of pediatrics. Bedside demonstration during the course of consultation is of inestimable value in learning the significance of physical signs peculiar to childhood.

Another advantage on the side of bedside teaching of physicians in practice must not be overlooked. Most of these men are busy, conscientious, overworked and underpaid practitioners. Their problems and difficulties can be appreciated much better by one who actually works with them and sees the "problems" at first hand. It is much more helpful and efficacious to be able to give advice adapted to the exigencies of the individual situation.

The personal contact with the physicians means a great deal. Sound and unsound ideas may be thrashed out with benefit to both parties. Advice and suggestions may be made with proper emphasis and with reasons and

explanations given. The alleged existence of an ultra-scientific attitude on the part of the recent graduate and the specialist may be exploded quickly when the general practitioner has a chance to talk things over with the specialist. In this way some of the reasons for skepticism of the general practitioner toward proved newer methods may be overcome.

One further advantage is to be listed. The cases which form the subjects of the consultations are usually the children of indigent low-income families. These patients certainly derive more or less benefit from the consultations, which up to now have been entirely unavailable to them both because of inaccessibility and expense involved.

SUMMARY

In the State of Maryland, the Bureau

of Child Hygiene has put on its staff a pediatrician to be available as full-time consultant for the general practitioners in a strictly rural area with a high infant mortality.

One of the objectives has been improvement of the pediatric knowledge of the local physicians. This has been attempted through the medium of using the individual consultations as opportunities for discussion and instruction.

Since its inception, there has been gradually increasing coöperation from the large majority of physicians. A total of 250 consultations were made during the first year. It is impossible to assay the results with any accuracy but some benefit has been derived. Advantages and disadvantages of this method of postgraduate education have been discussed.

What Every Health Officer Should Know

Vital Statistics*

JESSAMINE S. WHITNEY, F.A.P.H.A.

Statistician, National Tuberculosis Association, New York, N. Y.

WHEREVER statisticians are gathered together in large or small groups, the conversation ultimately turns on the question of quinquennial census taking. Since all our mortality rates are based on census figures, accurate population data are essential. In a country such as ours where the usual natural increase of the population has been upset by changes in birth rate, cessation of immigration, etc., former methods of estimating population are no longer of value. We have certain statistical tricks which help somewhat in arriving at such estimates in the early years of the intercensal period, but in the latter half we are hopelessly at sea in the whole matter. It is vital to the whole public health field that we become not only articulate in demanding a U. S. Government Census every 5 years, but that we become noisily and unpleasantly vocal on the subject in order to get congressional action.

The ageing of the population is a problem which confronts all vital statisticians today. The rapid decline in the birth rate, the decline in immigration, amounting in some years to an excess of emigration over immigra-

tion, and the saving of young lives through protective health measures are changing the age distribution of the population so rapidly that we may confidently expect an increase in the general death rate in the not too distant future.

This changing age picture necessitates modifications in death rates for comparative purposes. There is need either to standardize such rates for age, or to establish rates on the basis of the age groups of the population most affected by the disease or cause under consideration. For instance, the rates for degenerative diseases would be based on the population aged 45 and over, and the rates for communicable diseases of childhood on the population under 15 or 16.

The recent social welfare movements undertaken by the U. S. Government and various voluntary groups have created a demand for information not now called for in the standard birth and death certificates. Under pressure from such groups many states have been or are making changes to comply with such requests, with the result that there is considerable departure from the original plan to have "standard" certificates in use in all states. So a request was made to all state registrars to withhold, if possible, further changes until a general committee could take up the whole matter

* Read before the Health Officers Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

and recommend changes acceptable to all. Such a committee is now at work and expects to report next year.

The so-called Registration Area, which has been built up over the past generation, now covers all the 48 states for both births and deaths. We might call this the horizontal or extensive phase of vital statistics registration. Now that that objective has been attained, we are turning our attention to the refinement and improvement of the data reported in what we might call the intensive or vertical phase. One step toward this is the reallocation of deaths to usual place of residence of decedent and in the case of births to usual place of residence of mother. Several states are now doing this routinely to the very great improvement of the resulting data.

Then, too, there is the interchange of death certificates of persons dying in states other than their place of residence. The Vital Statistics Bureau of the U. S. Census is acting as the clearing-house in this procedure. Negotiations looking toward a similar plan with foreign countries are under way and Canada is already exchanging copies of certificates of alien decedents with border states.

Right at the moment the *International List of Causes of Death*, the basis of vital statistics in this country, is undergoing its 10 year revision by a committee of the American Public Health Association preparatory to the decennial meeting in Paris to be held in 1938, when over 40 countries which adhere to this list send representatives to consider revisions and make decisions to stand for the next decade. The United States changes suggested are along the line of reclassifications to meet the newer knowledge in pathology and bacteriology. Also, they attempt to eliminate certain common undesirable designations of disease, and to emphasize acceptable terms.

One of the most baffling problems is the assignment to a single cause a death for which the death certificate certifies more than one cause by the attending physician. Various methods of educating physicians to give their own version of the actual cause of death are being considered, involving some changes in the method of stating the inquiries on the certificate. Differences in handling this so-called "joint causes of death" problem by the various countries invalidates to a great extent comparability of vital data between countries, the very purpose for which the *International List* was established.

The whole question of accident statistics has become a staggering problem. "Deaths from all accidents" is now the sixth leading cause of death in the United States. If our purpose as public health workers is to prolong life as well as prevent disease, serious attention needs to be directed to this field. The Vital Statistics Section at this meeting has passed a resolution calling on Congress and the President for a 2 year appropriation to analyze the whole field of accident statistics, with a view to finding out where preventive efforts can best be concentrated.

I would not wish to conclude this brief presentation without paying tribute to the fine leadership in this field which we have in Washington in the Vital Statistics Bureau of the U. S. Census. With limited appropriations they have begun many innovations which will revitalize the whole field of vital statistics in this country. A small field force stands ready to give advice and counsel to local or state health officials on all matters pertaining to the vital statistics field.

Finally, I would urge you to consider the vital statistician in your department as a pathfinder. He should use the story of events already past to forecast drifts in the future and should

be a vital factor in helping to decide where emphasis in future plans and programs should be placed. Some health departments, both state and local, have expanded his functions and have made him statistician of the entire health department. Bureaus of communicable diseases, of nursing, and laboratory, all have statistical needs, and a well trained vital statistician can serve them all.

If your vital statistician is just a

fellow who sits in a corner and fiddles with figures all day and makes up a lot of complicated tables, the printing of which budget limitations usually prohibit, get rid of him, and get a statistician who can analyze those figures, interpret what they mean for future health work in words of one syllable, one who can really be a pathfinder and thus take his rightful place in the glorious business of life saving in which we are all engaged.

Personal Gifts Needed by Physicians

ON the occasion of the presentation of the prizes at the London Hospital Medical College, Dr. Robert Hutchinson, President of the Royal College of Physicians of London, summarized the qualities needed by a physician for success as follows:¹

First, good health, since there is nothing so tragic as a sick doctor; second, luckiness, though he warns that if one does not have luck, hard work and patience can make up to a great extent for the lack of it. Curiously, he places brains third, and warns that there must not be too many since it is unnecessary and perhaps even dangerous in medicine to be too clever. Extra diligence will make up for any shortage in brains. His next gift is equanimity, the power "to turn a keen untroubled face home to the instant need of things." Equanimity, however, must not be confounded with indifference. Next comes a sense of justice, first to the patient, then to one's self, to one's

professional brethren, and to the profession as a whole. He regards the sense of beauty, his next requirement, not as a luxury but as a saving grace, a compensation for the sordid things which must happen in a doctor's life, and a way of escape—"a sanifying and steadying influence." This may be displayed in a love of art, music, current literature, or anything which cultivates the higher tastes of life. He places last in his list—though he considers it the best of all—the sense of humor. This prevents one from taking his profession and himself too seriously and will remind him that there are other things in life worth having besides health. This sense cannot be cultivated in solitude. The possession of the senses of justice, of beauty, and of humor will go far to insure the equanimity needed by doctors to face the life they must lead.

What Every Health Officer Should Know

Industrial Hygiene*

LEVERETT D. BRISTOL, M.D., DR.P.H., F.A.P.H.A.

*Health Director, American Telephone and Telegraph Company,
New York, N. Y.*

IF I understand the mind of the health officer, he is interested primarily in organization, administration, and legislation, rather than in details pertaining to industrial toxicology or various industrial health hazards. Our Section has Committees on Lead Poisoning, Compensation, Volatile Solvents, Skin Irritants, Ventilation, and other allied subjects. The reports of these committees are printed in the *Association Year Book*, reference to which may be made for recent developments along these lines.

ORGANIZATION AND ADMINISTRATION

Possibly the most important development during the last year has been the creation of a Council on Industrial Health by the American Medical Association. This council is now in the process of being organized, and will function as a standing committee of the Board of Trustees of the American Medical Association.

During recent years, in addition to the work which various private industrial organizations have carried on, 3 federal agencies have been active in this field. The Division of Industrial Hygiene of the U. S. Public Health

Service has exerted a stimulating leadership in this field and has carried on scientific studies and promotional work with reference to various industrial health hazards. The Bureau of Mines in the Department of the Interior has carried on studies particularly among the mineral and allied industries, while the U. S. Department of Labor has been instrumental in securing uniform laws, and has carried on important statistical studies.

During the past year or two a marked advance has taken place in the organization of state and local bureaus of industrial hygiene. This advance undoubtedly has been due to the leadership of the Division of Industrial Hygiene of the U. S. Public Health Service, as well as the Committee on Industrial Hygiene of the Conference of State and Provincial Health Authorities of North America.

According to information supplied by the U. S. Public Health Service, the following 22 states at present have divisions of industrial hygiene in their state departments of health: Alabama, California, Connecticut, Illinois, Indiana, Iowa, Kansas, Michigan, Mississippi, Missouri, North Carolina, Ohio, Pennsylvania, Rhode Island, South Carolina, Tennessee, Texas, Vermont, Virginia, Washington, West Virginia and Wisconsin. In 2 states

* Read before the Health Officers Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

(New York and Massachusetts) such bureaus are established in the state departments of labor.

In addition to the development of such divisions in state departments of health and labor, 4 cities have inaugurated such divisions of industrial hygiene in their city departments of health, namely, Baltimore, Detroit, St. Louis, and San Francisco.

DEMAND FOR TRAINED PERSONNEL

One result of the marked advance in the development of Bureaus of Industrial Hygiene in state and local units has been an increased demand for trained personnel which it has been difficult to meet. This emphasizes the need for a more comprehensive program of teaching industrial hygiene in medical and public health schools throughout the country. In a survey which I made two or three years ago, it was found that only 13 out of 85 medical and public health schools in the United States and Canada give separate courses on industrial hygiene or industrial medicine. Several medical schools include one or two lectures on this subject in their general course on preventive medicine and public health, while a considerable number of such schools give no attention whatever to this important and growing subject.

COMPENSATION FOR OCCUPATIONAL DISEASES

The following 13 states now have compensation legislation covering a limited list of specific occupational diseases: Kentucky, Minnesota, Nebraska, New Jersey, North Carolina, Ohio, Rhode Island, West Virginia, Washington, Indiana, Pennsylvania, Michigan and Delaware. Eight states (Connecticut, Illinois, Missouri, New York, North Dakota, California, Massachusetts, and Wisconsin) have blanket provisions with more or less general coverage of diseases arising out

of or in connection with employment.

There is no question but that compensation legislation covering industrial accidents led to a rapid increase in safety activities throughout various industries of the United States. It is equally certain that the increasing legislation adding occupational diseases to the compensable list will further stimulate the development of industrial health promotion and sickness prevention.

REPORTING OF CASES OF OCCUPATIONAL DISEASES

The following 21 states now require the reporting of occupational diseases to state authorities: Alabama, Arizona, Connecticut, Georgia, Illinois, Kansas, Maine, Maryland, Massachusetts, Michigan, Minnesota, Missouri, New Hampshire, New Jersey, New Mexico, New York, Ohio, Oregon, Pennsylvania, Rhode Island, and Wisconsin.

INDUSTRIAL HEALTH APPRAISAL

The appraisal idea, which has been applied in past years to city and rural health units, recently has been extended to the industrial health program, and a Sub-committee on Industrial Health Appraisal of the Committee on Administrative Practice of the American Public Health Association is now engaged in furthering this plan. A paper by E. L. Simonds and E. R. Dejon, presented before our Industrial Hygiene Section at this meeting, indicates the views of one industrial organization which for the last 4 years has put the *Industrial Health Appraisal Form* into use as a regular company routine. It is hoped that other industrial organizations may see the value of applying the appraisal principle to their industrial health programs in the future.

ORGANIZED RESEARCH

In addition to research in industrial

hygiene now carried on by various governmental units and by many industrial organizations, there has been some recent development of special groups for organized research, including such agencies as the Air Hygiene Foundation of the Mellon Institute in Pittsburgh, and the Laboratory of Industrial Toxicology, of the DuPont Company in Wilmington, Del. In addition to these, one or two of the larger universities are now considering the development of special research institutes on industrial hygiene, with the idea of developing coöperative activities between local industries and university faculties.

INDUSTRIAL HYGIENE SECTION

The all-inclusive interests of the Section on Industrial Hygiene of the American Public Health Association may be noted by referring to the program of the current Section meetings, which covers, among others, such subjects as "Syphilis Control in Industry," "A Symposium on the Heavy Metals," "Lead Poisoning," "The Importance and Diagnosis of the Industrial Dermatoses," and "Vaccines Against the Common Cold."

In conclusion, attention should be called to recent significant experiments carried on by a group of research workers at the University of Toronto. Although these experiments are of a tentative and preliminary nature, it would seem that tiny traces of aluminum dust, added to the dusty, silica-filled air breathed by certain classes of miners, may some day stay the ravages of silicosis. In this study the addition of small quantities of metallic aluminum dust almost completely inhibits the solubility of silicious materials in laboratory beakers, and rabbits dusted with quartz to which less than 1 per cent of metallic aluminum dust had been added, showed practically no lung fibrosis, which is one of the characteristic pathologic findings in silicosis; while control rabbits dusted with quartz alone showed well developed silicosis. If these preliminary experiments are subsequently confirmed by other research workers, and are found practicable from the standpoint of the prevention of human silicosis, the time may come when the funeral ritual, "Dust to dust" may be adapted as a slogan by the industrial hygienist to read, "Dust *for* dust"!

What Every Health Officer Should Know

Health Education*

MARY P. CONNOLLY, F.A.P.H.A.

*Director, Division of Health Education, Department of Health,
Detroit, Mich.*

PUBLIC health education is beginning to be recognized as an important tool rather than a decorative feather in the cap of most health organizations. This change has been brought about by health officers as well as by better prepared health educators who together are studying the problems of their communities and the means by which many of them can be solved through education.

A marked change has taken place during the last 10 years in viewing the possibilities of health education. Health education started as a missionary movement—a way by which individuals, by certain practices, could work out a health salvation for themselves. A number of things were found to be wrong with the movement. First, but with few exceptions, there is no general rule for reaching the healthy life which can be applied to all persons; second, there are few personal practices which will do much to maintain health without medical guidance. This knowledge has shown the limitations of the earlier conception of health education and has opened up a vista which is as wide as the health officer cares to make it.

There are two schools of thought in

relation to the presentation of health material. One would employ the commercial technic, and the other regards this approach as unworthy of the serious subject and its effect upon the lives of many. Commercial technic is effective if it is modified and considers that men and women will pay for an article readily, while they change their habits only after much consideration and prayer. Then, too, the market for commodities assumes new fashions, while the health needs of a community change less rapidly. If the buyer finds that an article has been advertised as having virtues that he finds lacking, he will buy another product the next time. If he has been misled regarding the results of health practices he becomes a ready victim for the charlatan and the cults, and opposed to the whole system of scientific health protection.

Generally speaking, no two communities will respond to the same type of approach, any more than will all sections of one community respond in the same way. This means that to make a program effective many kinds of media will have to be employed at the same time. The newspaper and radio likely will affect about 20 per cent of a given community, and the other 80 per cent will be left untouched by these means. The health officer who relies upon a newspaper man alone to

* Read before the Health Officers Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

tell his story to the public will find that a large part of the population is not being impressed. The same will be found true when radio, or printed material, or group meetings are used exclusively.

As a result of a better understanding of the various avenues of approach necessary, few communities are boasting of results obtained by educational tricks.

Any health officer who wishes to sell public health to his community will have to start with a sound approach. This means that he must be sure that the material which he presents is scientifically honest, that it is vital to his community, and that he has facilities available for the residents to accept his advice. This is particularly important if he wishes to eradicate tuberculosis or syphilis. Perhaps his program is being presented to enable him to obtain these facilities. If it is, his approach will be different from that made when facilities are available. However, once the facilities are obtained, good practice dictates that a purely emotional approach will accomplish little without sound education disseminated by every possible means.

Syphilis programs are claiming the attention of most health departments today, and well they may. Those whose job it is to influence public opinion are concerned with the form this education will take, and whether some of the programs proposed will only continue the emotional response to the efforts. Syphilis is a communicable disease and education regarding it must take into consideration the rather sketchy ideas most persons have regarding the communication of disease and the need for supplying some basic education on which to pin specific education regarding syphilis. Consideration must also be given to the problem in a given community. Residents of homogenous communities in which public health

has been promoted are not moved to action by the knowledge that 40 per cent of certain racial groups are found to have syphilis. The more favored groups will assert that "it can't happen here," and go merrily on their way. Large sums of money are being appropriated for syphilis control and health educators will have to show some results for its expenditure.

The person employed today to do health education for a health department must know something of public health problems, sociology, economics, the interpretation of vital statistics in relation to population make-up, as well as advertising, salesmanship, journalism, and pedagogy.

Some few of the schools are making an attempt to provide this education for students. The report of the Committee on the Professional Education of Health Educators shows that serious consideration has been given to the preparation of the hybrid person who is to interpret the findings of science and the laboratories to the everyday man. The wise health officer will expect the same professional standards from his health educator that he expects from his epidemiologist or his director of nursing.

The first step in any health education program should be made with the employees of the health organization. Every health department has many non-professional employees—inspectors, clerks, stenographers, and others who are concerned with routine activity. These people can be of great value in promoting the program, or they can destroy the sincere efforts of the health officer and the health educator. The inspector who tells all and sundry, in and out of work, that he would not have his children protected against diphtheria, has no place in a modern health department if his opinions cannot be changed. Intensive education for all employees which will make them

feel important messengers of the program pays big dividends.

The Fuller Brush man is still keeping a good part of the country supplied with brushes and brooms. He goes from door to door and brings his wares to the people. The public health nurse brings the public health program to those who would never know of it in any other way. She is the salesman who must take the time to discuss the merits of the suggested practices, to listen to the objections, and within the limits of environment show the family the advantages of preventive medicine. She will be successful if she has learned the educational approach and the motives which will cause persons to accept what she has to offer.

Physician preparation is the next step. No wise merchant would buy a page of advertising in the *Saturday Evening Post* without first being sure that his product is understood and for sale by the retailer. The practising physician is the purveyor of preventive medicine. Unless he is kept informed and made an active part of the program, he will likely discredit the effort because he is not ready to dispense the service. The local medical society provides the best means for reaching the physician, and its official sanction gives a coöperation which cannot be obtained in any other way.

Those who influence public opinion are important allies of a health department and deserve to receive information before the program is given to the public. The clergy of all denominations, teachers, social workers, club members, and others who feel that their word counts, will influence many persons and establish constructive attitudes toward public health problems.

The attention of the press will come when the health department has something to offer. Newspapers want news which will be read. The modern health department is teeming with news

of vital interest to every person in the community. The vital statistics gathered by the health department are a record of the joys and sorrows of the people. If they are interpreted intelligently to the press, they form a base on which much health information can be built. The persistent reporter who wants to know the why of things is not being just annoying. He is trying to find the answer to the countless questions which will come to his readers from the simple statement of facts made by the health officer. If he is given an honest picture of the situation, with enough details to help him to understand it, rarely will he betray the health officer. If on the other hand, he is given a garbled account which endeavors to cover inefficiency or lack of knowledge, the health officer may well fear the worst.

The radio offers a medium which reaches many homes. The health message is padded between commercial programs for which all sorts of attention-getting devices are used. The health message must be unique and refreshing and arrest attention without being blatant. Real skill is necessary to accomplish this. Real personalities are needed to convey the message.

Literature is valuable if it is carefully prepared, well printed and illustrated, and distributed with discrimination. Very few health departments have a sufficient budget to buy quantities of good literature, and the American Medical Association, American Public Health Association, national health organizations, the insurance companies, and a few other commercial concerns, prepare and distribute pamphlets which may be used by health organizations. The insurance companies produce the best of the commercial literature which usually is prepared by scientific writers and which does not aim to sell a specific product. There are some duplicating

machines and other devices which may be used by the health organizations to prepare material which has local significance. With a certain amount of ingenuity and a small budget, much can be accomplished by the organization personnel.

Person to person education is important and requires an endless amount of time, but the results repay the effort.

The success of health education will depend first upon the standing of the health organization which promotes it, and the sincerity of purpose which it has established; and then, upon the preparation and adequacy of the health educator and the coöperation which he receives from the entire staff.

The day of policing is pretty well over for public health organizations. It is being replaced by sound education by which the community will be able to make decisions which have social value.

One of the most urgent needs in

health education today is a technic for evaluating programs as a whole, and then the constituent parts of the program in order that the greatest results may be obtained from the expenditure of money available. A committee within the Public Health Education Section is studying methods of evaluation and it is hoped that some worthwhile recommendations will come from this meeting. The Committee on Objectives likewise will report on efforts to clarify the relationships of public health educators, school health educators, and the countless other persons who find health education a part of another job for which they were employed.

Public health educators are realizing their responsibilities, their need for understanding the problems of human beings in relation to health, and the best means by which persons may learn to solve these problems.

What Every Health Officer Should Know

Public Health Nursing*

NAOMI DEUTSCH, R.N., F.A.P.H.A.

*Director, Public Health Nursing, U. S. Children's Bureau,
Washington, D. C.*

IT would seem appropriate to begin a review of recent developments in public health nursing with a discussion of activities in the field of public health nursing education, since this is fundamental to all public health nursing activities.

In December, 1918, the Rockefeller Foundation invited a group of nursing educators, physicians, public health nurses, and individuals eminent in the field of public health and social research to consider this topic. "The proper training of public health nurses" was the problem presented to the committee. The study upon which this group embarked, under the chairmanship of Josephine Goldmark, has been generally known as the Goldmark or the Rockefeller Report on Nursing and Nursing Education in the United States. Soon after this study began it became clear that, if sound conclusions were to be attained, the entire field of nursing had to be taken into consideration.

In preparing to solve the problem confronting Miss Goldmark and her committee, namely, that of meeting the need for more adequate nursing serv-

ice in the field of public health, an analysis of the basic professional education was found to be of paramount importance. Although the Goldmark report was followed by illuminating surveys conducted by the Committee on the Grading of Nursing Schools, the program in the basic professional education for public health nurses is still a challenging problem. In reviewing professional histories public health administrators still find applicants with inadequate basic nursing preparation.

If the Curriculum Guide for Schools of Nursing, prepared by the National League of Nursing Education and published in 1937, could be put into universal practice, nursing education would be fundamentally improved. In this, increased emphasis is given to the social and the economic aspects of health and disease. Teaching methods are given the prominence they deserve. In the past nurses have relied largely on content to guide their teaching and have not always known how to stimulate and encourage the individual to acquire health knowledge and to put it into practice.

Not until there is a complete separation of the responsibility and the budget for hospital service from those for the school of nursing will this broader concept of nursing education

* Read before the Health Officers Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 7, 1937.

be realized. Tax appropriations or educational endowments are needed to make a high standard of professional nursing education more universally available. There is increasing agreement that the requirements for entrance to the school of nursing should include a broad and sound preliminary education.

Although the Rockefeller Report was published as early as 1923, it gave as a part of its first conclusion that as soon as practicable all agencies employing public health nurses should require a postgraduate course in public health nursing. The survey of public health nursing made by the National Organization for Public Health Nursing in 1932, and published in 1934, shows from a sampling of urban and rural public health nursing service that only 7 per cent of the public health nursing staff, not including supervisors and executives, had completed an accredited course in public health nursing. A study made 5 years later, in 1937, and as yet unpublished, shows that 29 per cent of the nurses employed in the official agencies studied had completed an approved course.

Although this is a gratifying increase, the demand for public health nurses meeting the minimum requirements for public health nursing positions as set forth by the National Organization for Public Health Nursing still greatly exceeds the supply. Stipends granted by state health departments to candidates for preparation in public health nursing have played a large part in increasing this number. That the problem of further preparation for staff nurses and potential staff nurses is still a large one is evidenced by census figures for public health nurses, which have been compiled by the public health nursing consultants of the U. S. Public Health Service and the U. S. Children's Bureau. On January 1, 1937, 21,656 public health nurses were employed by

official and unofficial agencies in rural and urban areas.

Curricula in public health nursing are now offered in 17 universities and colleges throughout the country. At a conference on public health nursing education held at the U. S. Public Health Service in Washington, D. C., on April 1, 1937, at which directors of courses in public health nursing and consultants from the U. S. Public Health Service and the U. S. Children's Bureau were present, the following statements were made with regard to the qualifications of students on stipend who attend these courses:

1. The majority of students on stipend met the matriculation requirement of the respective universities; the exception to this was a group of Negro nurses attending a special curriculum.
2. The current selection of students by the state health departments was superior to the previous selections. The greatest value from the period of study can be attained only if the student has satisfactory background and has demonstrated her ability and general aptitude for public health nursing.
3. The personal qualifications of the applicant as they influence her competence for the public health nursing field should be carefully considered.
4. It is desirable that students should have had an introduction to public health nursing through experience in visiting nursing.
5. Preference in granting stipends should be given to candidates having had an adequate clinical preparation.

With regard to the curriculum the group stated:

1. There should be close correlation between field practice and theory.
2. It is recommended that in both theory and field practice the promotion of health, the prevention of disease, and the nursing care of the sick be emphasized, since increasing emphasis is being given to comprehensive community public health nursing services.

The outstanding needs in public health nursing education were given as:

1. Basic nursing preparation of the student should be improved; if necessary it should

be supplemented before formal training in public health nursing is begun.

2. The establishment of additional facilities in conjunction with the health department for supervised rural field practices is essential to meet the needs of the increased student group.

3. Opportunities for advanced preparation in control of syphilis, control of tuberculosis, orthopedic nursing, and maternity nursing should be established under the direction of university departments of nursing education.

In order that this additional preparation of the public health nursing personnel may result in improving the quality of performance, supervisory and advisory services are playing an increasingly important part in the administration of public health nursing. Under the auspices of Western Reserve University and the National Organization for Public Health Nursing two conferences on supervision of public health nurses have been held for supervisors in the Midwest.

"Teaching on the job" by supervisors is a necessary corollary to adequate staff preparation. The increasing demand for supervisors prepared to do this is a significant development.

Throughout the country public health nursing services have been increased and extended, especially in rural areas, through grants-in-aid to the states under the provisions of the Social Security Act. Nursing programs are not being enlarged as a separate entity but as one part of the community public health plan. New objectives in the general health department program are reflected in the nursing services. For example, in certain areas reports of activities indicate that public health nurses are including programs for the control of syphilis and pneumonia in the general family health services. In some of the programs promotion of better nutrition is being stressed. The nurses' knowledge of this subject is being enriched and the program guided by special consultants in nutrition.

Several private agencies are studying ways and means of improving the nursing service for patients having chronic diseases.

Public health nursing services in school health programs are being more closely integrated with courses of study and with the activities of the teaching staff.

The increasing demand for a more complete maternity program is directing attention to rural areas that have established nursing services in the home during delivery. Varied methods of administering these services are being inaugurated. When these are compiled and analyzed, important data on administrative practices in home delivery nursing services should be available.

Locating crippled children, assisting with arrangements for their hospital care, and assuming greater responsibility for their after-care are developments in the local nursing program.

As more opportunities for social and health services in the community are developed, public health nurses are becoming increasingly aware of the need for establishing definite relationships with workers in the fields of nutrition, social work, mental hygiene, and education, so that the varied programs may achieve their common goal of better health and social security for the community.

In the American Public Health Association the Public Health Nursing Section seeks to integrate its activities with those of other sections and to interpret underlying principles and current trends in the practice of public health nursing and in turn gain knowledge concerning the activities of other groups. The section is closely identified with the National Organization for Public Health Nursing, which is the standard and policy making organization for the profession. The American Public Health Association's Public

Health Nursing Section promotes these standards through the activities of its committee members. Public health nursing is represented on the four Standing Committees of the Association. Throughout the past year section sub-committees have been appointed to study relationships between official and nonofficial public health nursing agencies; to study the function of the Public Health Nursing Section in its relation to other national organizations; and a committee was appointed to define public health nursing problems needing research and study.

TO SUMMARIZE THE DEVELOPMENTS

There has been an extension in the facilities for public health nursing education. A curriculum guide for schools of nursing has been published which should favorably influence basic nursing education. There has been an increase in the number of public health nurses who have completed an accredited course in public health nursing.

Following the expansion in the public health program, nursing services have developed more comprehensive, well balanced activities, including in certain sections programs of syphilis and pneumonia control, greater stress on

teacher participation in school health programs, more complete maternity programs emphasizing nursing care at delivery, postpartum services, and care of the sick in rural areas. The greater number and improved quality of supervisory and advisory nursing services give planned direction to these expanding services.

The National Organization for Public Health Nursing as the professional organization for public health concerns itself with standards in all aspects of public health nursing. It is the center for pooling and interpreting information, and it gives direction to the developments in this field, guiding the advancement in public health nursing through committee reports, meetings, and publications.

By participating in joint activities the Public Health Nursing Section of the American Public Health Association interprets these standards and principles to the allied groups represented in the various sections of the Association. Through this relationship the public health nursing group gains knowledge of developments in other fields, thus aiding the extension and progress in public health nursing services.

Federal Facilities to Expedite Emergency Sanitation Measures*

R. E. TARBETT, F.A.P.H.A.

*Senior Sanitary Engineer, U. S. Public Health Service,
Washington, D. C.*

THE Ohio River flood of 1937 was the first instance of a major catastrophe in which immediately available federal funds and personnel permitted the expediting of emergency sanitation measures, and in which there was thorough coördination of all federal facilities in connection therewith.

The availability of federal relief appropriations for organized work relief projects in the area affected and the possibility of immediate transfer of these funds, and personnel, to flood emergency activities were conditions which may not and probably will not exist when the next catastrophe of major proportions occurs. In considering the availability of federal facilities, therefore, immediately available emergency funds for labor, materials, and the like must not be included to any appreciable extent. However, trained personnel to assist the state and local health agencies will be available in the future as was the case during the recent flood.

A brief description of the administrative procedures in Washington, with some comments, will indicate that these procedures were the logical and perhaps the best ones to be followed in

any major catastrophe. That there was some lag in their establishment is true, as is also the fact that their establishment was due in part to lack of coördination of flood emergency activities in the field.

In any flood emergency several activities must be carried on simultaneously by various agencies. In order to be most effective there should be a clear understanding by each agency of its duties, if overlapping on one hand, or failure to carry out certain functions on the other, are to be avoided. Likewise, where the duties of two or more agencies dovetail, proper coördination is necessary. At certain stages of the emergency certain lines of endeavor temporarily assume greater importance than others, a fact that all agencies should recognize.

The need for delineation of federal activities, as well as proper coördination, was recognized soon after the probable magnitude of the flood was realized.

On Sunday, January 24, at the direction of the President, the heads of the various federal agencies in any way connected with flood emergency activities met at the National Red Cross headquarters. At this first meeting the duties of each agency were determined, as well as the manner in which each could best coöperate with the other. In this coördinated effort the National

* Read at a Joint Session of the Conference of State Sanitary Engineers and the Public Health Engineering Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 5, 1937.

Red Cross was considered as having the same status as a federal agency. Each agency's representative in Washington became the liaison officer between his agency and all others and had power to act for his agency without the necessity of higher approval. Regular meetings were held daily by this group until the emergency was past.

Following each meeting the field officers in the flood area were advised accordingly. Through this emergency committee difficulties arising in the field were quickly settled and good coordination of activities was brought about.

In the future it would appear desirable to assemble promptly such a federal committee whenever a catastrophe may be impending in order that the emergency work may progress as smoothly as possible from the start. While it is important that such a federal emergency committee assemble promptly, it is much more important that similar state committees be organized and be prepared to function much as did the federal committee during the recent flood.

As soon as it was evident that the flood was to reach extraordinary proportions an engineer officer of the Public Health Service was assigned to each of the state health departments in the flood area to cooperate with them. This was promptly followed by the assignment of all available engineers in the Service to flood duty. At the same time arrangements were made hurriedly by the Public Health Service to furnish biologic supplies as needed.

At the meeting of the federal agencies on Sunday, January 24, the Works Progress Administration requested that Service engineer officers be detailed to act as technical advisers in connection with sanitary work carried on by that organization and also to act as liaison officers between the WPA and the state

and local authorities. Under certain limitations Civilian Conservation Corps personnel was made available to the Public Health Service by the Army for sanitary work. Immediately after the meeting the engineer officers assigned to state headquarters were informed as to their duties as technical advisers and liaison officers in connection with sanitary work.

It was also arranged that Service medical officers would act as liaison officers between the National Red Cross and the state health authorities. Medical officers were promptly assigned to the various district headquarters of the Red Cross.

With this arrangement there was a close "tie-in" between the state health departments and the federal agencies engaged in the health and sanitation work which is believed to have contributed to the rapid progress of the work with relatively little confusion.

It was evident at the start that some confusion existed in the supplying of biological supplies. A Service officer was therefore placed in direct charge of this work. He was in touch with all of the possible sources of biological supplies and was able to have them supplied with the least amount of trouble.

It was thought that some difficulty might arise because of the demand for chlorine and chlorine compounds, and a somewhat similar scheme was set up under one of the engineer officers. It was found, however, that the chemical companies had the field well covered and this service was not necessary.

It was realized that as the flood waters began to recede trained sanitary engineers would be needed to supplement the state forces and to act as technical advisers to the WPA district administrators. It was rather essential that such engineers be trained in state health department procedure, since no training and little or no

supervision could be given prior to their employment or while they were on the job. It was also essential that, to be of greatest assistance, these additional engineers be in or near the flood area ready for call. This group was recruited from the state health departments of states adjoining the flood states. Each of the state health officers was called by telephone and asked if he could furnish engineers from his staff and how many. The selection was left to him. Where men were urgently needed at the time of the call he was requested to get them off by the next train. The men taken on were made Collaborating Sanitary Engineers in the Public Health Service and paid a small salary in addition to the regular travel and subsistence allowance for government employees. Under this arrangement no financial loss was suffered by these volunteers and thus there was no incentive or desire to return home before their services could well be dispensed with.

At all times there were engineers on the call list ready for prompt departure to any area in which they might be needed.

This plan worked so smoothly and efficiently that it is questionable if it could have been improved upon. The time elapsing between the call to the state health officers and the departure of the men was only a matter of 4 or 5 hours, even though some requests for personnel were made after 10 P.M.

In addition to the 25 engineers from the Public Health Service assigned to the states affected, 37 were obtained from state health departments, 3 from one city, and 1 from a county, a total of 66. One consulting engineer with health department experience volunteered his services and was added to the force.

It has been suggested that a reserve corps of sanitary engineers be established who would be available on call

for emergency duty. Under the law it is possible for the Public Health Service to offer reserve commissions to engineers, but not possible, however, to call such reserve officers to duty for training at regular intervals.

At first thought it would appear desirable to have a reserve corps to supplement the regular corps of the Public Health Service in times of widespread disaster. There are, however, disadvantages which would appear to outweigh the advantages. One advantage claimed would be the rapidity with which the reserve corps could be mobilized. Theoretically this would be the case while actually it probably would not. Certainly mobilization of any group could not have been more rapid than was the case during the recent disaster when the state health officers designated their assistants who could, and would, go.

With a reserve corps there would of necessity be different grades with different rates of pay. During an emergency the work of all would be substantially the same. Attempting the same work with officers of different grades and rates of pay is not conducive to efficiency. Reserve officers on active duty would receive only a mileage allowance while in a travel status. This allowance would have to cover all of their travel and subsistence expenses. The distance travelled by any reserve officer would be relatively short, and his mileage allowance small; hence he would find, after the first few days, that his expenses were being paid by himself. This would not contribute to either efficiency or willingness to remain until the officer's services were no longer needed.

These and other reasons make it undesirable to attempt to establish a reserve corps for occasional disaster emergency duty.

In order that emergency sanitation measures may be carried out rapidly

and efficiently in any catastrophe such as a major flood there are required labor, supplies, equipment, and transportation, in addition to properly trained technical personnel. These must generally be obtained through other agencies than the health departments. It is desirable therefore that all agencies, both federal and state, promptly organize a committee which will define the activities of each agency and coördinate these activities in such a manner as to promote efficient performance.

In the field of sanitation the Public

Health Service might well be considered the source from which the state health departments would draw technical personnel necessary to supplement their own forces, the Public Health Service to draw upon the states not affected for additional personnel when its own becomes exhausted. In addition to assisting the state health department the engineers furnished by the Public Health Service would act as liaison officers between any federal agencies engaged in sanitary work and the state health authorities and also act as technical advisers to such federal agencies.

Discussion

J. K. HOSKINS, C.E.

Senior Sanitary Engineer, U. S. Public Health Service, Cincinnati, Ohio

THE general coördination of federal facilities for emergency sanitation measures in effect during the Ohio River flood of 1937 has been outlined by Mr. Tarbett. That they could be improved upon in some respects is doubtless true but that they worked with reasonable efficiency and promptness over an extensive area is also certain. So far as the observations from those of us in the field could determine, the extent of coöperation with state and municipal authorities was quite complete.

The general plan of the Public Health Service, in so far as the sanitation activities were concerned, was to:

1. Assign one of its sanitary engineers to each state affected by the flood to collaborate with the chief engineer of the state and through him make available federal facilities for sanitation operations.

2. Be prepared to meet all reasonable requests for emergency engineering and scientific personnel submitted by the field sanitary engineers.

3. Establish only broad policies of procedure and rely upon the field directors to employ measures best suited to handle the particular problems encountered.

4. Remove so far as possible administrative restrictions that might tend to delay immediate action.

There are 3 principal classes of assistance needed in emergency sanitation work that can, to a large extent, be planned for in advance. These are:

1. Directing and scientific personnel
2. Emergency labor
3. Materials, supplies and transportation

Sanitary engineering personnel and other professional assistance was generally adequate and promptly available as a result of the action of the state health officers in placing members of their forces at the call of the Public Health Service. The men selected were trained in state sanitation activities and quickly gained the confidence of local authorities in the areas to which they were assigned.

Emergency labor was generally readily obtained from federal organizations but, as Mr. Tarbett points out, such a reservoir of assistance may not be always at hand. Planning for such emergency help in future disasters would seem to be a function of state

and local agencies. It should be possible for states to work out feasible arrangements with state and county welfare departments through which labor could be quickly supplied and paid. Definite plans for the rapid assembly and assignment of sufficient labor for the protection and reestablishment of the essential public services would materially lessen disaster losses. A well organized and trained reserve corps of labor foremen designated for particular duty on emergency call within the state for each county or other unit would be of especial value. Periodical relief of such workers is also a prime essential as is also provision for their remuneration. An emergency fund for such purposes might be established or arranged for through suitable legislation or at least authority granted for use of the regular state allotments to spending agencies with the promise of reimbursement. The designation of some one state official for the management and arbitrary control of such emergency funds would probably be advisable.

Obtaining necessary materials and supplies quickly is generally a difficult procedure in times of disaster. Federal agencies were particularly helpful during the 1937 flood, especially the Works Progress Administration because of its well organized purchasing department, throughout the inundated area. There are, however, definite restrictions imposed upon federal expenditures. Here too state and municipal governments might give thought to plans for ascertaining sources of essential emergency equipment and perfecting methods for their procurement when needed. Established purchasing authorities, if empowered to act with the minimum restrictions in times of

disaster, could avoid wide confusion and indiscriminate and duplicate buying. An essential of such a centralized procurement agency is the prompt establishment of a representative with adequate assistance at the scene of the disaster, and with adequate authority to act. The close coöperation of such an agent with federal organizations that may be engaged in emergency relief measures is an obvious advantage.

Transportation facilities are generally disrupted in any extended catastrophe. Highways to the affected area are likely to be destroyed or rendered impassible, railroads are equally vulnerable, and other methods of transport affected. As a result our highly specialized systems of food distribution are upset and essential supplies are difficult to obtain. Here again careful planning could alleviate much distress in the early periods of disaster. Certainly the water and sewage treatment plants should have ample reserve supplies of essential chemicals, fuel, and standby power always available to meet any reasonable, unforeseen requirement. Standing arrangements with bus and truck owners for emergency use of their rolling equipment would insure the prompt movement of essential sanitary supplies.

In general, it is believed, the individual states coöperating with county and municipal authorities could, with profit, give consideration to the development of plans for the putting into force of emergency sanitation measures and the reestablishment of sanitary services disrupted by flood and other disasters within their boundaries. The present provision of emergency labor, supplies and materials under competent direction are essential parts of such a program.

Scarlet Fever Control*

EDWARD R. KRUMBIEGEL, M.D.

*Director, Bureau of Communicable Diseases, Health Department,
Milwaukee, Wis.*

TO determine what assurance of clinical protection the 5 standard injections of scarlet fever toxin offer a person if originally Dick positive, the attack rate among immunized persons should be compared with the attack rate among persons known to be Dick positive but unimmunized, and both groups should be studied over an identical time.

On March 12, 1934, the Milwaukee Health Department adopted the procedure of the Scarlet Fever Committee for Dick testing persons over 18 months of age, and the subsequent immunization of those showing a positive reaction. Opportunity has been afforded to observe the result of this work covering a time during which the incidence of scarlet fever has been exceptionally high, reaching epidemic proportions in 1934 and 1935. In 1934 there were given and read 15,642 Dick tests, of which 10,500, or 66 per cent, were positive. Among these Dick positive reactors 1,769 received no toxin for immunization, while 6,497 received in 1934 either a standard 5 dose course or as many doses as they elected to receive. None of these subsequently received any artificial immunization. The 5th dose of toxin was received by

3,914 persons, of whom 3,532 had a re-Dick test and appeared for reading. Of these, 240, or 6.9 per cent, were positive and 183 received a 6th dose (5th dose repeated).

Table I shows the relationship between the positive Dick reactors of 1934, the amount of toxin in doses received and completed in 1934, and the incidence of scarlet fever following completion of the course of immunization. All cases have been followed through March 12, 1937.

TABLE I
*Positive Dick Reactors Developing
Scarlet Fever*

<i>Dosage</i>	<i>Total</i>	<i>Developed S.F.</i>	<i>Case Rate Per cent</i>
0	1,769	226	12.77
1	682	42	6.16
2	462	21	4.55
3	765	21	2.74
4	674	6	0.89
5	3,731	33	0.88
6	183	2	1.09

Among Dick positive reactors there is a progressive decline in the percentage developing scarlet fever, from

NOTE: Throughout this paper the term scarlet fever is used to represent this disease with rash, as the clinician ordinarily reports it. Only a small percentage of the scarlet fever cases reported to the Milwaukee Health Department are *scarlatina sine eruptione*. The relationship between immunization and "scarlatinal sore throat" will be discussed in a future paper.

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-sixth Annual Meeting in New York, N. Y., October 6, 1937.

12.77 per cent in the unimmunized group to 0.88 per cent in the 5 dose group. Over 3 years the case rate was more than 14 times higher in the former group than in the latter. The case rates for the 4, 5, and 6 dose groups closely approximate each other.

In order to determine whether the immunity derived from toxin is lasting, Table II is presented. In it the groups from Table I are divided into yearly periods to show the time of development of scarlet fever after the Dick test or the last dose of toxin.

tion of scarlet fever. In reality, many of the unimmunized Dick positive reactors developed immunity spontaneously through sub-clinical attacks of the disease. The theory of latent immunization through sub-clinical infection is strongly supported by observations of Zuger¹ and Gordon *et al.*² To evaluate the influence of latent infection on the comparative figures it would be necessary to retest these same unimmunized positive Dick reactors each year. Immunization through sub-clinical infection would

TABLE II
Positive Dick Reactors Developing Scarlet Fever

Dosage	Total	Scarlet Fever 1st Year		Scarlet Fever 2nd Year		Scarlet Fever 3rd Year	
		Total	Case Rate Per cent	Total	Case Rate Per cent*	Total	Case Rate Per cent*
0	1,769	147	8.31	46	2.84	33	2.09
1	682	21	3.08	11	1.66	10	1.54
2	462	9	1.95	6	1.32	6	1.34
3	765	13	1.70	5	0.66	3	0.40
4	674	4	0.59	2	0.30	0	0.00
5	3,731	14	0.38	11	0.30	8	0.22
6	183	0	0.00	1	0.50	1	0.50

* Case rate percentages have been corrected for the number presumably developing immunity during each preceding yearly period because of contraction of scarlet fever.

The advantage which the various dosage groups have over the no dose group during the first year wanes when compared for the 2nd and 3rd years. For example, while the ratio of case rates for the no dose and 5 dose groups is nearly 22 to 1 for the 1st year, it is only $9\frac{1}{2}$ to 1 during the 2nd and 3rd years. At first glance it appears that the immunity diminished greatly in the 5 dose group toward the beginning of the 2nd year. While it is possible that many of this group who lost their immunity did so within a year, the above figures would require that over 50 per cent did so. It must, however, be remembered that the no dose group table is corrected only for those presumed to have developed immunity in each year through contrac-

tion of scarlet fever. In reality, many of the unimmunized Dick positive reactors developed immunity spontaneously through sub-clinical attacks of the disease. The theory of latent immunization through sub-clinical infection is strongly supported by observations of Zuger¹ and Gordon *et al.*² To evaluate the influence of latent infection on the comparative figures it would be necessary to retest these same unimmunized positive Dick reactors each year. Immunization through sub-clinical infection would

exert its greatest influence in the 1st year during which scarlet fever was prevalent in epidemic proportions. By comparing case rates for the various dosage groups with the no dose group for the 2nd and 3rd year, no waning of immunity is detected for the 3, 4, or 5 dose groups, while definite decrease is apparent for the 1 and 2 dose groups.

DICK TESTING OF PERSONS WHO HAVE HAD SCARLET FEVER

Dick tests were done on individuals who had recovered from scarlet fever. Only cases were considered in which the diagnosis had been verified by one or the other of two health department contagious disease diagnosticians. Table III shows the results of the

TABLE III

Positive Dick Reactors After Recovery from Scarlet Fever

	Total	Positive	Negative	Per cent Positive
Dick tested during 1st year after recovery	225	29	196	12.9
Dick tested during 2nd year after recovery	478	76	402	15.9
Dick tested during 3rd year after recovery	212	40	172	18.9

testing when done within the 1st, 2nd, and 3rd years following recovery from the disease.

There are 3 per cent more positive reactors during the 2nd year after recovery than during the 1st year, and 3 per cent more during the 3rd year than during the 2nd year. This rise in percentage of positive reactors strongly suggests that some individuals who have acquired active immunity through an attack of the disease subsequently lose it.

The 12.9 per cent shown to be positive when tested within 1 year after recovery from scarlet fever suggests that either a large percentage of persons do not develop immunity from a single attack of the disease, or if the percentage developing immunity is nearly 100 per cent, then over 12 per cent lose their immunity in less than 1 year. Perkins,³ in returns from 1,016 cases collected from January, 1924, to April, 1927, reports 14 per cent positive Dick reactors in persons of all ages with a history of a past attack of scarlet fever, while returns from 735 cases Dick tested in the convalescent stage showed only 8 per cent positive Dick reactors.

In Milwaukee in 1934, 5,965 cases of scarlet fever were reported, and of these 68 developed scarlet fever again following recovery but before December 31, 1936. One case developed within 1 month after recovery and could therefore be classified as a recrudescence rather than a second at-

tack. In more than 75 per cent the diagnosis was verified in each attack by one of two health department diagnosticians. Within the first year after recovery, 37 second attacks occurred; within the second, 18 attacks; and within the third, 13 attacks.

If the percentages, shown in Table III to remain Dick positive after an attack of scarlet fever, indicate true susceptibility, it becomes possible to anticipate the number of persons who should have had second attacks within yearly intervals. The number of anticipated cases should approximate the number which actually developed each year. Table IV shows these calculations.

Comparison of the anticipated and actual numbers of cases during these yearly intervals shows the actual numbers equal, on an average, only 60 per cent of the anticipated number.

Ando, Kurauchi, and Nishimura⁴ have shown that the filtrate of the broth of hemolytic streptococcus cultures contains two substances capable of causing skin reactions. One is relatively heat labile and the other relatively heat stable. Their work, together with that of Toyoda and Futagi,^{5a} indicates that the thermolabile portion is exotoxin. They were able to prepare this in relatively pure form and concluded it is the true toxin of scarlet fever, contains no nitrogen, and never causes allergic reactions. On the contrary, they concluded that the thermo-stable portion is endotoxin, is

TABLE IV

Anticipated and Actual Number of Scarlet Fever Cases Among Those Who Had a Previous Attack of Scarlet Fever

	<i>1st Year</i>	<i>2nd Year</i>	<i>3rd Year</i>	<i>Total</i>
Number having had one attack of scarlet fever	5,965	5,924	5,903	
Per cent Dick positive after scarlet fever	12.9	15.9	18.9	
Number susceptible	769	942	1,116	
Per cent susceptibles attacked *	8.31	2.84	2.09	
Number anticipated cases	64	27	23	114
Number actual cases	37	18	13	68

* Refers to percentages of known Dick positives attacked within various 12 month periods taken from Table II.

identical with nucleoprotein obtained by extraction of the washed bacteria, is capable of acting as an allergen, and often produces allergic skin reactions in persons immunized against streptococci or scarlet fever.

Toyoda, Moriwaki, and Futagi^{5b} state that skin tests on children who previously had scarlet fever gave 32.7 per cent positives with their Dick toxin while with heat-labile exotoxin only 3.4 per cent were positive. The discrepancy in numbers of anticipated and actual cases of scarlet fever shown in Table IV can be explained on the basis of the 12.9 per cent reacting positively within 1 year after recovery. This figure is probably about 40 per cent too high and the error is probably due to positive tests on persons immune to scarlet fever but showing

allergic skin reactions to the nucleoprotein in the test material. The 3 per cent yearly increase in number of positive reactors is apparently reasonably accurate.

As shown in Table V, the percentage of cases having second attacks of scarlet fever only slightly exceeds the percentage of negative Dick reactors contracting scarlet fever, and also only slightly exceeds the percentage of positive Dick reactors who contracted the disease after receiving the standard 5 doses of toxin.

This, taken into consideration with the percentage of persons who show a falsely positive reaction as already mentioned, hardly seems to justify as a public health measure the Dick testing and immunization of persons giving a bona fide history of a previous attack

TABLE V

Scarlet Fever Among Dick Negatives, Artificially Immunized Dick Positives, and Those Who Have Had the Disease

	<i>Total</i>	<i>Developing Scarlet Fever</i>	<i>Per cent Developing Scarlet Fever</i>
Primary negative Dick tests in 1934--no immunization	5,142	45	0.93
Positive Dick in 1934 received 5 doses of toxin in 1934	3,731	33	0.88
Positive Dick in 1934 received 5 doses of toxin in 1934--negative re-Dick in 1934	3,292	28	0.85
Had scarlet fever in 1934	5,965	68	1.12

of scarlet fever. A pure or nearly pure exotoxin for testing would make such work less objectionable if it is undertaken.

VALUE OF DICK TEST IN CLINICAL PRACTICE

1. *The Primary Negative Dick Test*

In 1934 there were recorded 5,142 primary negative Dick reactors. As shown in Table V, of this number 48, or 0.93 per cent, developed scarlet fever before March 12, 1937.

The explanation may lie in faulty technic in giving the test or its interpretation. In Milwaukee every effort has been made to follow exactly the technic as outlined by the Dicks. If the human element of error entered, it is believed it would be introduced to at least an equal degree by others doing the same work under similar circumstances.

Does the reactive power of the skin vary at times in the same individual? Eddy and Mitchell⁶ have shown this to occur occasionally for scarlet fever toxin in measles and in the febrile stages of such diseases as pertussis, poliomyelitis, and varicella. This must play a negligible rôle in this series.

The work of Hooker and Follensby⁷ on "heterologous" toxins has demonstrated the existence of at least two thermo-labile hemolytic streptococcus toxins. This work deserves serious consideration as it may explain the occurrence of scarlet fever with rash in persons previously tested with the strong toxin A producing Dick ii strain but later infected with organisms such as the "Cook" strain which is a powerful toxin B but weak toxin A producer.

If, however, immunity as indicated by a negative Dick test can be lost when acquired actively and naturally by an attack of scarlet fever, or actively and artificially by toxin injections, why may it not be lost in a

small percentage of cases when acquired actively and naturally through a sub-clinical attack of the disease?

2. *The Negative re-Dick Test*

Table V shows that of 3,292 persons who had a negative re-Dick test after receiving the 5 standard doses of toxin 0.85 per cent developed scarlet fever within 3 years. Among the group of 3,731 persons who completed the 5 dose series, only 0.88 per cent contracted the disease, in spite of the fact that 199 were not retested, and of 240 showing a positive retest only 183 received a 6th injection. Moreover, of the 183 who received a 6th injection, 2 contracted scarlet fever for a case rate percentage of 1.09. One of these 2 had a negative re-Dick test after the 6th dose of toxin. Thus, the practical advantage of re-Dick testing has been negligible.

In this connection the work of Hooker and Follensby⁷ on "heterologous toxins" must again be considered. They estimate only some 2 or 3 per cent of young adults react positively to a mixture of toxins A and B, and negatively to toxin A alone. Contraction of scarlet fever with rash by a Dick negative person does not necessarily indicate a loss of previously sustained antitoxic immunity but may be due to infection with a strain of organisms producing a "heterologous toxin."

3. *The Primary Positive Dick Test*

I have repeatedly noticed that some individuals, especially adults, when returning for reading of a Dick test, show an intense reaction involving a large area and having a fairly dark red elevated center. Often a pale pink or dark red indurated area measuring over 1 cm. in diameter is noted. None of these reactions resembles the mild erythematous blush of the true reac-

tion. I have then repeated the Dick test at once, using the test material from another manufacturer. On reading this second test, it is often noted that the reactions are much smaller in size and some of the smaller ones have failed to appear at all.

Ando and Ozaki⁸ attribute such reactions to nucleoprotein in the Dick toxin and from the above results it would seem that the nucleoprotein content in various lots of Dick toxin is not constant. Ando, Kurauchi, and Nishimura⁴ state "the nucleoprotein solution is able to evoke skin reactions even in a high dilution (1:1,000-1:9,000 dilution)." Ando and Ozaki⁸ state "generally speaking the influence the N.P. in the filtrate has on the results of the Dick test is marked when a weak toxin is used in a lower dilution though also the N.P. content of a culture varies with the strain used. Accordingly, a high dilution of a potent toxin should be preferred for the Dick test, but the use of a purified toxin would be preferable."

Using purified toxin and culture filtrate, both standardized on young strongly positive reactors and applying both to persons ranging in age from 6 to 15 years, Ando and Ozaki⁸ showed that 31.2 per cent reacted positively to purified toxin and 33.2 per cent reacted positively to culture filtrate. They state "The difference in percentage of positives to both toxins is not so marked considered as a whole, but the difference is rather considerable when the percentage of positives in the higher age groups is considered."

That use of the standard Dick test control will not entirely avoid this difficulty is shown by Green⁹ who states "In the present instance abundant evidence has been forthcoming that an apparently identical reaction to crude filtrate in two susceptible individuals may mask considerable variation in their reaction to the separated exotoxin and endotoxin."

Accordingly, it seems that even among school children a small percentage of primary positive Dick reactors are immune to scarlet fever, and that the percentage of error increases with increase in age groups.

4. The Positive Re-Dick Test

When a re-Dick test is positive in an individual who has recently completed a standard 5 dose series of toxin, are we justified in assuming that the person is still susceptible to scarlet fever? As said, a small percentage were probably immune but allergic to the nucleoprotein before the injections were begun. As shown by Toyoda and Futagi^{5a} and Ando,¹⁰ the nucleoprotein fraction of the Dick toxin may act as an allergen in some persons so that while they are being immunized they will become allergic to thermo-stable endotoxin. These individuals are also immune to scarlet fever but show a positive re-Dick test.

In studying the results of re-Dick testing in school children in Milwaukee in 1934, it was found that in 12 schools only the test material of manufacturer A had been used and in 8 other schools only the material of manufacturer B.

TABLE VI

Re-Dick Testing of School Children with Test Material of Manufacturers A and B

	Laboratory A			Laboratory B		
	Total	Positive	Per cent Positive	Total	Positive	Per cent Positive
Children retested	1,610	68	4.2	1,155	100	8.7
Over 10 years old	453	28	6.2	321	32	10

Table VI shows the results of such re-Dick testing with products of these manufacturers.

Testing was done 2 weeks after completion of immunization. Only children who had received the standard 5 dose course were considered. Product A shows 4.2 per cent positives for all retested, and product B shows 8.7 per cent, while the average of the two is 6.1 per cent. This may account for the variation in percentage of negative re-Dicks reported by different authors. Children over 10 years of age showed 7.8 per cent positive re-Dick tests, a higher percentage than the 6.1 per cent shown by the entire group. The percentage was higher for these older children with each of the two manufacturer's products. Bacterial contamination of the material, with resulting skin infections, cannot be ascribed as the cause of this variation because only previously unused vials of test material were sent to these schools.

While the test material was undoubtedly accurately standardized for its true or thermo-labile exotoxin content the lots of various manufacturers vary as to their nitrogen-containing fraction or nucleoprotein. Veldee,¹¹ using commercial unconcentrated toxins from several laboratories, shows variation in total nitrogen content. Using his figures, the nitrogen toxin ratio as mg. of nitrogen per 100,000 S.T.D. is 8.93 for product of laboratory F and 6.23 for that of laboratory E, illustrating the variation that may occur.

CONCLUSIONS

1. During 3 years the case rate for scarlet fever was more than 14 times higher in unimmunized Dick positive reactors than in those who completed the standard 5 dose course of toxin.

2. During 3 years the immunity derived from 4 doses of toxin was as effective as that from 5 doses.

3. During 3 years the case rates for scarlet fever were lower in primary negative Dick reactors and positive reactors who completed the standard 5 dose course of toxin than for those who previously had an attack of scarlet fever.

4. During 3 years the practical value of re-Dick testing has proved negligible.

5. A culture filtrate free of, or as near as possible free of, endotoxin is desirable, at least for the purpose of skin testing.

National Health Conference - A Review

A NATIONAL Health Conference, called by the Interdepartmental Committee to Coördinate Health and Welfare Activities, was held in Washington, D. C., July 18 to 20. This committee was appointed by the President in August, 1935, following the passage of the Social Security Act, "in order that the full benefits of the various federal programs under the Act provisions might reach with minimum delay and maximum effectiveness the individual men, women, and children for whose aid and service the program was brought into existence." This committee consists of Josephine Roche, Chairman, former Assistant Secretary of the Treasury, in charge of the U. S. Public Health Service; Eugene L. Bishop, M.D., Executive Secretary; Arthur J. Altmeyer, Chairman of the Social Security Board; Milburn L. Wilson, Under Secretary of Agriculture; Oscar L. Chapman, Assistant Secretary of the Interior; and Charles V. McLaughlin, Assistant Secretary of Labor.

A Technical Committee on Medical Care has been working for some months under the Interdepartmental Committee. This committee consists of Martha M. Eliot, M.D., Children's Bureau; I. S. Falk, Ph.D., Social Security Board; and of Joseph W. Mountin, M.D., George St. John Perrott, and Clifford E. Waller, M.D., of the Public Health Service.

There were 171 persons invited to participate in the Conference by the Interdepartmental Committee. These persons were invited merely as indi-

viduals and for what they might contribute, rather than as representatives of particular groups. The Conference was carefully prearranged with respect to personnel, make-up, and agenda. The presence in large numbers of representatives of the consumers of medical care lent it interesting color and distinguished it from previous meetings of its kind. In addition to the persons formally invited to be present there were approximately an equal number of invited observers who were excluded from participation and discussion, together with members of the press. A classification of those who participated in the Conference may be summarized as follows:

Total number of delegates 171
 Delegates having a degree of M.D. 53
 Persons identified with
 Public health agencies 20
 Social and welfare agencies 20
 Labor 20
 Journalism 11
 Hospital management and organization 9
 Local, state, and federal government officials, exclusive of public health and hospitals 9
 Industry 9
 Agriculture 8
 Women's organizations 5
 Economists 4
 Educators 4
 Nursing 3
 American Legion 3
 Dentistry 3
 Foundations 2
 Miscellaneous organizations 10

Of the total, some 35 persons were identified with the American Public Health Association as Fellows or members.

This Conference, which was held at the suggestion of President Roosevelt

after considering the preliminary report of the Interdepartmental Committee presented to him in February, 1938, was opened by Miss Roche, as Chairman, who read a message from the President. The President enumerated some of the strides which have been taken by medical science and public health within recent years. He mentioned the extension of public health and maternal and child welfare services under the Social Security Act, the launching of a special campaign to control syphilis, the establishment of the National Cancer Institute, and the use of federal emergency funds for the expansion of hospital and sanitation facilities, the control of malaria, and many related purposes. The President pointed out that, in spite of these steps forward, there is need for a coördinated national program of action. Such a program, he said, must necessarily take into account the fact that millions of citizens lack the individual means to pay for adequate medical care. He stated that the economic loss due to sickness is a very serious matter, not only for many families with and without incomes but for the nation as a whole. He asked that the Conference plan a long-range comprehensive program providing for the most efficient coöperation of federal, state, and local government with voluntary agencies, professional groups, media of public information, and individual citizens.

At the outset, Miss Roche expressed the hope that the Conference might contribute to two ends: (1) a better understanding of national needs in the field of health and medical care; (2) the formulation of policies which will enable the medical and other professions, private organizations, federal, state, and local agencies, and individual citizens to coöperate in efforts to meet these ends.

Miss Roche went on to say that the

people of the United States are alert and determined that the frequently difficult but ultimately sure and progressive processes of democracy shall serve all the people and that human conservation is an obligation of government. She pointed out that the findings of the survey show that the gross sickness and mortality rates for the poor of our large cities are as high today as they were for the nation as a whole half a century ago. The average person in a relief family experiences 3 times as many days of disability annually as the average person in the upper income group. One in every 20 family heads in the relief population is unable to work because of chronic disability, as contrasted with only 1 in 250 heads of families with incomes of \$3,000 or over. Miss Roche pointed out that, when translated into human reality, the statistics show that 40 per cent of the counties in the United States where 18 million people have their homes have no registered general hospital, and that among 50 million Americans who live in families receiving less than \$1,000 income a year, illness and death increase their toll as income goes down, medical care decreasing sharply as need for medical care mounts.

There were addresses by Katherine Lenroot, Chief of the Children's Bureau, Department of Labor, and Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service. There followed a discussion of national health needs and the speakers included Dr. Irvin Abell, President of the American Medical Association; William Green, President of the American Federation of Labor; Dorothy J. Bellanca, Vice-President of the Amalgamated Clothing Workers of America; Mrs. H. W. Ahart, President of the Associated Women, American Farm Bureau Federation, and Dr. Hugh Cabot, Consulting Surgeon of the Mayo Clinic.

The Chairman inquired whether anyone was prepared to challenge the statement of need as made by the technical experts, and there was no response.

The second day of the Conference was utilized for the presentation by the technical experts of a general program of medical care, together with plans for insurance against loss of wages during sickness, a study of hospital facilities and studies of medical care for the medically needy.

In referring to the recommendations from the Technical Committee on Medical Care, Miss Roche pointed out that these recommendations were presented to President Roosevelt in February, 1938, and that it was at his suggestion that the National Health Conference was called. She stated that the Conference was not asked to take formal action on any part of these recommendations. They were put forward merely as a basis for discussion and the Interdepartmental Committee, she said, sought the frankest discussion of the means of improving the health services and medical care of the people of the United States.

THE NATIONAL HEALTH PROGRAM IN SUMMARY

The following represents a summary of the National Health Program as recommended by the Technical Committee on Medical Care to the Interdepartmental Committee to Coördinate Health and Welfare Activities;

A study of health and medical services in the United States indicates that deficiencies in the present health services fall into 4 broad categories:

1. Preventive health services for the nation as a whole are grossly insufficient.

2. Hospital and other institutional facilities are inadequate in many communities, especially in rural areas, and financial support for hospital care and for professional services in hospitals is both insufficient and precarious, especially for services to people who cannot pay the cost of the care they need.

3. One-third of the population, including persons with or without income, is receiving inadequate or no medical service.

4. An even larger fraction of the population suffers from economic burdens created by illness.

In its report the committee submitted a program of 5 recommendations for meeting with reasonable adequacy the existing deficiencies in the nation's health services. Although estimates of the total additional annual costs to federal, state, and local governments were submitted, the committee did not suggest that it is practicable to put into effect immediately the maximum recommendations. Rather it stated the broad problem and possible solutions and contemplated a gradual expansion along well planned lines with a view to achieving operation on a full scale within about 10 years.

Recommendation I—The expansion of public health and maternal and child health services.

The committee recommended the expansion of existing coöperative programs of the Social Security Act.

- a. The expansion of general public health services (Title VI). Prevention occupies the first place in this recommendation and increasing federal participation is proposed to promote a frontal attack on certain important causes of sickness and death for the control of which public health possesses effective weapons. In order to strengthen public health organization; to eradicate tuberculosis, venereal diseases, and malaria; to control the mortality from pneumonia and from cancer; and to promote mental and industrial hygiene; an estimate was made of \$200,000,000 annually for an adequate program with the proposal that approximately one-half of these increased funds be provided by the federal government.

- b. Medical and nursing care of mothers and their new-born infants, medical care of children, services for crippled children, consultation services of specialists, and more adequate provisions for the postgraduate training of professional personnel are included in this part of the recommended program. The objective sought is to make available to mothers and children of all income groups and in all parts of the United States

minimum medical services essential for the reduction of our needlessly high maternal mortality rates and death rates among infants, and for the prevention in childhood of diseases and conditions leading to serious disabilities in later years. A gradually expanding program reaching at least by the 10th year a total additional annual expenditure of \$165,000,000 was recommended. Again it was proposed that approximately one-half of the cost should be met by the federal government.

With reference to Recommendations II, III, and IV, the expansion of medical services and facilities, the committee explored the adequacy of services for the sick, the sickness experience of broad groups of the population, and the availability of professional and hospital services for these groups. The committee concluded that the needs for diagnostic and therapeutic services to individuals are greatly in excess of the facilities, even when supplemented by a strengthened program of preventive services as proposed in Recommendation I. The committee found that current practices in the provision of medical services and facilities fall far short of meeting these needs. It took account of personnel and facilities, of financial support of services required by persons who are themselves unable to pay for the care they need, of the sickness burdens of self supporting persons, of methods of paying for medical care, and of assuring income for workers who are disabled by sickness. It concluded that these needs warrant an expansion of medical services and facilities on a broader front than that contemplated in Recommendation I alone.

Recommendation II—The expansion of hospital facilities.

After making a special study of deficiencies in existing hospital and other institutional facilities, the committee was impressed by the increasing part which hospitals play in the health and sickness services. The committee found the hospital accommodations and or-

ganizations throughout the country ill adapted to the varying needs of people living under different social, economic, and geographical circumstances. In hospitals offering general care the percentage of beds supported by patients' fees is out of proportion to the ability of the population served to pay, and many general hospital beds are empty a large part of the time. There are too few low cost or free beds to satisfy the needs. There are wide areas—some 1,300 counties—having no registered general hospitals, and many others are served only by one or two small proprietary institutions. Only in large city hospitals have outpatient clinics been developed to any considerable extent. Governmental tuberculosis sanatoria and mental institutions tend to be overcrowded or are otherwise restricted in funds or personnel in rendering the community service for which they should be equipped.

The committee recommended a 10 year program providing for the expansion of the hospital facilities of the nation through the provision of 360,000 beds, including general, tuberculosis, and mental hospitals in rural and urban areas, and by the construction of 500 health and diagnostic centers in areas inaccessible to hospitals. These new hospitals or units would require financial assistance during the first 3 years of operation. Averaged over a 10 year period the total annual cost of such a program, including special 3 year grants for maintenance of new institutions, is estimated at \$146,050,000, of which construction would total \$110,650,000, and 3 year maintenance \$35,400,000.

Recommendation III—Medical care for the medically needy.

Grouped together under this recommendation is the need for persons without income and supported by general relief and, as well, families with small incomes. The committee pointed out that these persons are doubly handi-

capped. They have higher rates of sickness and disablement than prevail among groups with larger incomes. They have lesser capacities to buy and pay for the services they need. Current provision to assist these people is not equal to the need. The committee recommended that the federal government, through grants made to the states, should implement the provision of public medical care to two broad groups of the population. (1) Those for whom government has already accepted some responsibility through the public assistance provisions of the Social Security Act, through work relief programs, or through provisions of general relief and (2) those who though able to obtain food, shelter, and clothing from their own resources are unable to procure necessary medical care. In this way the test of indigency was removed from the requirements for relief. The committee estimated that, on the average, \$10 per person annually would be required to meet the minimum needs of these two groups for essential medical services, hospitalization, and emergency dentistry. This part of the program might be begun, it was suggested, with the expenditure of \$50,000,000 the first year, gradually expanded until it reached the estimated level of \$400,000,000 which would be needed to provide minimum care to medically needy groups. Again the committee recommended that one-half of the total annual cost be met by the federal government.

Recommendation IV—A general program of medical care.

Directing attention to the economic burdens for self-supporting persons created by sickness, the committee pointed out that there is need for measures which will enable such people to anticipate and to meet sickness costs on a budget basis. Summarizing their conclusions, as a result of many studies,

the committee stated that the costs of sickness are burdensome more because they fall unexpectedly and unevenly than because they are large in the aggregate for the nation, or on the average for the individual family. Except in those years when unemployment is widely prevalent, sickness is commonly the leading cause of social and economic insecurity. Without great increase in total national expenditures, the burdens of sickness costs can be greatly reduced, through appropriate devices to distribute these costs among groups of people and over periods of time.

In recommending the consideration of a comprehensive program designed to increase and improve medical services for the entire population, the committee pointed out that such a program would be directed toward closing the gaps in a health program of national scope left in the provisions of Recommendations I and III. To finance the program it was proposed that two sources of funds might be drawn upon: (a) general taxation or special tax assessments, and (b) specific insurance contributions from the potential beneficiaries of an insurance system. The committee recommended consideration of both methods, recognizing that they may be used separately or in combination.

Recommending that such a program should preserve a high degree of flexibility, in order to allow for individual initiative, and for geographical variations in economic conditions, medical facilities, and governmental organization, the committee indicated its belief that it should provide continuing and increased incentives to the development and maintenance of high standards of professional preparation and professional service. It was further pointed out that this plan should apportion cost and the timing of payment so as to reduce the burdens of me-

cost and to remove the economic barriers which now prevent the rendering of adequate care.

The committee made clear that in planning for a program of medical care of a magnitude to serve the entire population, this aim must be regarded as an objective to be fully attained only after some years of development. The rôle of the federal government, according to the committee, should be principally that of giving financial and technical aid to the states in their development of sound programs through procedures largely of their own choice.

Recommendation V — Insurance against the loss of wages during sickness.

The committee recognized the importance of assuring wage earners continuity of income through periods of disability. While a disability compensation program is not necessarily part of the medical care program, the cost of compensating for disability would be needlessly high if wage earners generally did not receive medical care necessary to return them to work as soon as possible. The committee believed that temporary disability insurance can be established along lines analogous to unemployment compensation and that permanent disability insurance may be developed through the system of old age insurance.

THE COST OF THE PROPOSED PROGRAM

Estimating the maximum annual cost to federal, state, and local governments of Recommendations I, II, and III, with duplications eliminated, the committee estimated that about \$850,000,000 of new funds would be required annually at the full level of operation, to be achieved within a 10 year period. This figure, however, was presented primarily as a gauge of need.

The committee pointed out that in proposing Recommendation IV for an adequate general program of medical

care, the maximum prospective annual cost would be in the vicinity of \$20 per person per year, or no more than is already being spent through the private purchase of medical care. However, in considering the possibility that a national health program more limited in scope than that which is outlined in the entire series might be adopted, it was believed that Recommendations I and II should be given special emphasis and priority. "Summarizing the entire report, the Technical Committee on Medical Care stated its conviction that, as progress is made toward the control of various diseases and conditions, as facilities and services commensurate with the high standards of American medical practice are made more generally available, the coming decade under a national health program will see a major reduction in needless loss of life and suffering and an increasing prospect for longer years of productive self supporting life in our population."

SUMMARIES OF THE CONFERENCE

In speaking over the radio during the Conference, Dr. Thomas Parran pointed out that the Conference was considering large scale measures to deal with the whole problem of health and medical care in the country at large. He emphasized the fact that not only the humanitarian basis of good health was considered but the savings to the nation which will accrue from a more healthful population. He added that the Conference differed in at least two important respects from similar conferences held in the past. In the first place it brought together not only the medical and other professional experts but representatives of labor, the farmers, and other groups of citizens who receive or would like to receive adequate health services and medical care. Dr. Parran quoted President Roosevelt as saying that, while the professional experts can help, nevertheless

the ways and means of dealing with this problem "must be determined with a view to the best interests of all our citizens." Secondly, he said, the National Health Conference is distinguished by the fact that it is intended to lead to action.

It was plain through Dr. Parran's address and many others that the people of the country realize that they are not obtaining the full benefits of modern medical knowledge with its tremendous scientific advances, and with even greater emphasis it was brought out that they are demanding more help and medical service.

Significant among the declarations of Dr. Parran were that, comprehensive and complicated as the whole program may seem, it is in no sense revolutionary. In each of its parts it seeks to do better, more skillfully, more universally for all the people, what is already done to conserve health in some communities or for some people. No radical change in medical practice is contemplated, according to Dr. Parran. He further pointed out that the first concern of the Conference is to reduce the amount of sickness rather than simply to spread the cost of sickness, and he pointed out that in this respect the American Medical Association and the representatives of all consumer groups were agreed. Also in agreement were many who felt that the underprivileged groups of our population who cannot provide good medical care for themselves need help from public funds if they are to have the benefit of medical science.

Charles W. Taussig, President of the American Molasses Co., summarized his own opinion which appeared to be widely shared at the Conference:

There seems to be a general acceptance at this Conference of the factual presentation of the desperate need for more adequate medical service to the underprivileged. Some opposition, however, has been voiced to a

federal subsidy to take up this slack. In other words, as a mass problem the need for a greatly augmented medical service is unanimously recognized, but some of us, unfortunately, hesitate to go beyond the mere recognition of the problem. A reason frequently given for this timidity is that a coordinated attack by the federal, state, and local governments on this problem of proper medical care will in some unexplained way destroy our democratic system of government. I recognize that what we have been discussing at this conference puts democracy to a severe test, for one of the first questions that we must ask of the democratic process is: Can it meet the recognized social requirements of our people?

The American concept of democracy has never carried with it the implication of a changeless political, social, and economic order; yet it has become the habit of a certain group to brand every suggested effort to improve the condition of the underprivileged and to make less cumbersome our governmental processes as being destructive to democracy. Totalitarians recognize such mass problems as we are considering here. They deal with them on a mass basis. But the genius of democracy lies in its ability to reduce the problem of the masses to its component parts of individual human needs and desires, and to solve the problem on that front.

We underestimate the virility of our democracy when we refuse to meet an acknowledged need, not because we do not know how to meet it, not because we lack the resources to meet it, but because we are afraid that some alien political philosophy may creep upon us unaware and destroy our institutions. If democracy in the United States has become such a feeble thing, it can no longer serve us. It is a paradox that the most vociferous vocal defenders of democracy join with Hitler and Mussolini in proclaiming democracy's alleged inability to cope with complex social and economic problems.

Let us remember that democracy is a sword as well as a shield, that its purpose is not only to defend old liberties, but to make new social and economic conquests as well. This Conference presents a magnificent challenge to the democratic process.

Adjourning after 3 days, the Conference adhered to the suggestion made by the Chairman and took no vote. It was announced that the government

Technical Committees would work over the material as presented and the criticisms made during the Conference with the objective of formulating legislative bills suitable for consideration by

the Congress, and it was suggested that a similar conference might be called within a few months to consider a definitive legislative program based on these recommendations.

CONFERENCE GLEANINGS

"Public health may well be the next great social issue in this country." Thomas Parran, M.D., Surgeon General, U. S. Public Health Service.

"We cannot attack a 10 billion dollar program with small change." Josephine Roche, Chairman, Interdepartmental Committee.

"Those of us who are concerned with the progress of medical science usually think that the great events of medicine occur only in the research laboratory or the operating room. We are witnessing here in Washington another kind of progress in medicine—an effort to put medical science to work. The National Health Conference may well be the greatest event in medical science which has happened in our time." Thomas Parran, M.D.

"The individual in need is indivisible as to his relief and his medical care." M. Antoinette Cannon, New York School of Social Work.

"This conference will mean further shifting of the center of gravity in this problem toward the consumer." Hugh Cabot, M.D., Rochester, Minn.

"It is indeed futile to increase the demand for better medical and health services without increasing the facilities." Charles W. Taussig, President, American Molasses Company.

"Our studies of the money value of a human life show that, taken as a whole, our human assets are at least five times as valuable as our economic assets." Louis J. Dublin, Ph.D., Metropolitan Life Insurance Company.

"Our purpose is not to create a Utopia but to face and accept at least minimum responsibilities for medical care." Fred Hochler, Director, American Public Welfare Association.

"The real question for us to face is what is the intelligent, decent, and adequate way to do this thing?" President Frank Graham, University of North Carolina.

"The consumer interest is with the medical profession now. It may not always be." John P. Koeckler, M.D., Milwaukee, Wis.

"The prospect of having more people lean

for medical care on the broad shoulders of Uncle Sam has been distressing to a considerable number. I would rather have more people lean on the broad shoulders of Uncle Sam for this purpose than on the narrow and cadaverous shoulders of the Elizabethan poor laws. They were not a modern solution." Paul Kellogg, Editor, *Survey Associates*.

"There have been so many surveys of national health needs that, as one mother, I fear that our children will grow up to be unhealthy adults before we as a nation put into effect a sound and adequate health program." Mrs. J. K. Pettengill, President, National Congress of Parents and Teachers.

"Complacency now has no justification. The situation would seem to be too big for the resources of medicine to meet alone." Robert Osgood, M.D., Harvard University.

"In health protection self help is preferable to outside aid; government intervention in medicine is desirable as a last, not a first, resort." S. S. Goldwater, M.D., New York City Commissioner of Hospitals.

"If a wider application of the voluntary insurance principle will produce a readier flow of effective service, the principle is entitled to support." S. S. Goldwater, M.D.

"Medical care should be locally rather than nationally administered. The effective and economical administration of medical aid for the masses by huge federal agencies is well nigh impossible." S. S. Goldwater, M.D.

"Only a few years ago my people—the field workers, the packing house workers, etc.—did not know what it meant to demand that their needs, their lives, their happiness be considered. They were only half Americans with no voice in the government, with no part in planning this democracy. But now these men and women are organized and they have learned how to ask for what they want, how to demand what they need." Florence Greenberg, Chicago.

"I maintain that the first problem for this government is to relieve poverty and I maintain, as one who understands something of the nature of the practice of medicine, that medical care is not the most important

problem before the people of the United States today." Morris Fishbein, M.D., Editor, *Journal of the American Medical Association*.

"It is true that if the economists could show us how to produce and distribute an income equal for the health and other needs of every family, the need for many public health measures would be minimized. The interrelationship between poverty and disease is well known. Disease begets poverty and poverty in turn creates more disease. At the present time, however, our proven ability to prevent disease exceeds greatly our proven ability to control other causes of poverty. . . . Medicine and public health should lead economics rather than follow it. The application of preventive medicine offers the best opportunity to interrupt the downward spiral, to tear out the roots of poverty and the consequences of ignorance by attacking the one most readily preventable fact." Thomas Parran, M.D.

"I propose to recognize the needs which have been dramatized for us, to go home and to recommend to the American medical profession through the *Journal of the American Medical Association* and through the House of Delegates that they do all they can to meet these immediate and pressing needs without sacrificing the standards of medical care which will give the people good medical service." Morris Fishbein, M.D.

"My respect for the medical profession to which I belong is so great that I am sure that the quality of medical care which physicians provide will never depend on the method by which they are remunerated for their services." John P. Peters, M.D., Professor of Medicine, Yale University.

"If all of the groups of the country must help in solving this great problem of medical care, that means that the government will have to do it, does it not? And, really, the federal government is not an invading hostile power that knows nothing about the needs of this country. After all, what is it? It is ourselves, ourselves organized, and surely it is more or less susceptible to our influence." Alice Hamilton, M.D., Consultant, U. S. Department of Labor.

"You may rest assured that in any of the efforts which are made for the betterment of the health care of the people of this country you will have the wholehearted coöperation of the American medical profession." Irvin Abell, M.D., President, American Medical Association.

"The following is a typical case from the National Youth Administration: In a Middle-western industrial city, 1,800 boys and

girls were given a thorough physical examination. Forty-three per cent of them were found to be unemployable by private industry because of their physical conditions, but it was estimated that with corrective medical treatment this large portion of youth, who were occupationally handicapped because of physical defects, could be reduced to 8 or 10 per cent." Charles W. Taussig.

"If I may for a moment speak to you as the head of an industrial corporation, I should like to emphasize that the expenditure of \$850,000,000 for public health does not frighten business. Business bears a far greater financial burden now, due to our neglect of inadequate health control, than its share of the tax burden will be under the proposed plan. The annual toll of preventable illness measured in terms of money runs into billions. Progressive business will regard an adequate health service as a subsidy to industry—not as a burden." Charles W. Taussig.

"The participation of a labor representative at a conference of this kind to consider national health needs with a view to formulating a national program is in itself a significant departure and an indication of the growing recognition that the problem of health is no longer a private and purely professional concern, but that it is manifestly one of the widest possible public urgency." Dorothy J. Bellanca, Vice-President, Amalgamated Clothing Workers of America.

"In the large cities as well as in the rural areas the low income groups experience sickness and mortality today as if there had been no progress at all during these past fifty years. The results of medical science have reached those who could afford them." Dorothy J. Bellanca.

"There can be no acceptance by the medical profession of any system of medical care which is based on the idea that the well-to-do shall receive one quality of medical care while the farmer, the laborer, and the white collar worker are to be placated with a wider distribution of an inferior medical service." Irvin Abell, M.D.

"Spot maps developed by the Council on Medical Education and Hospitals of the American Medical Association reveal that only 13 counties in the United States are more than 30 miles distant from an acceptable general hospital, and in 8 of these counties there are less than 5 people per square mile of territory." Irvin Abell, M.D.

"According to the method proposed for testing the adequacy of distribution of hospitals in the United States, as presented by

the American Medical Association, one hospital of 10 beds in New York City and one in Chicago would be assumed to meet completely the needs of these communities. Measures of the actual utilization of hospitals are necessary. Otherwise the conclusions are absurd." Professor C.-E. A. Winslow, Yale University.

"The medical profession agrees with all other agencies on the importance of the following objectives: The provision of good medical care for all the people; the development of comprehensive preventive and public health services; the development of appropriate measures to combat specific health problems; and a continuous, orderly improvement of the distribution of medical services and hospital facilities, both by geographic and economic divisions." Irvin Abell, M.D.

"It is easy to say that there are many thousands or millions living in economic conditions where health and happiness are impossible in a democracy as vast as ours, but I would like you to realize that this problem varies not only from state to state; it varies so much in the different counties or townships in each state, that most formulas imposed on our people as a whole would do a great deal more harm than good. It is with this purpose in view, and as a result of the very able address delivered by Miss Josephine Roche at the meeting of the American Public Health Association last year, that the American Medical Association has inaugurated and is pushing to completion a painstaking study of the needs of medical care and the method for their provision in each county in the United States." Irvin Abell, M.D.

"I was interested to hear the president of the great American Medical Association refer to the survey which they are now carrying out. I do not myself feel much confidence in the result because I am not clear by precisely what method physicians are to know about people whom they never see. The people who get no medical care obviously do not crowd the doctors' offices and precisely how they are to arrive at figures which will be more convincing, if perchance we need any figures that are more convincing, is beyond the limits of my slow mind." Hugh Cabot, M.D.

"The day is not so very long gone when the medical profession of not only this but every other country took the general and very barren view that all medical problems were their problems and that the whole problem of sickness and preventive medicine was the problem of the physician. There

has been accumulating evidence that the consumer is beginning to wake up to the fact that he has a collateral interest in this problem, that he is the one who is paying the bill, and that he has a right to a very large word in what is done and in how it is done. Here in this Conference for the first time I hear clearly and boldly and bravely and gallantly stated the problem of the medical consumer." Hugh Cabot, M.D.

"It is my firm belief that this Conference marks the ridge of the hill between the old indifference to health as a matter of national concern and a new understanding that health is the first and most appropriate object for national action." Thomas Parran, M.D.

"I think we shall have action on several aspects of our problem because it would appear that at the present time people in general are beginning to take it for granted that an equal opportunity for health is a basic American right. They are thinking just a little ahead of the law makers and even, I fear, ahead of the practitioners of public health and of clinical medicine." Thomas Parran, M.D.

"The social significance of this Conference lies in the fact that for the first time we can be optimistic that action will follow plans." Thomas Parran, M.D.

"The ideal traffic plan is not that which provides a first-aid station at all intersections and streamlined ambulances to carry away the victims of traffic accidents." Thomas Parran, M.D.

"I see in the discussions of this Conference an extraordinarily touching appeal to the medical profession. It has been the boast of the medical profession, and the just boast, and the source of proper pride, that if a woman came with a sick child to an individual physician and said, 'My child is suffering and we want you to care for it,' that he never failed to respond. Now what has happened here this week is that the representatives of millions of men and women in the United States have come to the medical profession as a group and said, 'Our members are sick and suffering and we want medical care for them, and we want means provided by which we can pay.' Is it possible, is it conceivable that that appeal is going to be rejected? I think not." C.-E. A. Winslow, Dr.P.H.

Pending final action by the House of Delegates, "The Association may well abide by the fundamental principles and policies already established. . . .

These principles and policies do not forbid, nor do they seem to contemplate any opposition to, a well considered expanded program of medical services, particularly preventive medical service, when the need can be established. Neither is there any fundamental principle or policy which in any manner opposes aid to the indigent or even to what are called the medically indigent if their medical indigence can be estab-

lished, provided such aid comes through agencies which will not tend to lower the quality or standards of medical care." Editorial comment on the National Health Conference, from the *Journal of the American Medical Association*.

Visual Education—The Oberlaender Trust

VISUAL education in the field of public health has a great future in the United States. There are people in every community who would like to see such work established on a permanent basis, and undoubtedly much progress will be made within the next few years. The Trustees of The Oberlaender Trust have felt that a distinct contribution could be made to this movement by making the experience of the German pioneers available to public health officials in America.

As a first step in this direction, and with the definite objectives of helping to make the general public better acquainted with fundamental questions of health, and of stimulating interest in the founding of health museums in various parts of the United States, the Trust has purchased two large collections of models from the Deutsches Hygiene Museum in Dresden. The first, containing more than seventy separate exhibits, has been placed temporarily in the New York Museum of Science and Industry. The other, a set of thirteen models, has been donated to the Museum of Science and Industry in Chicago. All are duplicates of material in the Dresden Hygiene Museum.

The collection in New York, which is

shown under the title "The Exhibit of Man," features a Transparent Man and Miss Anatomy, other models ranging from a blood cell enlarged a thousand times to a figure showing the circulation of the blood through the heart and important blood vessels. Requests have been received for permission to copy the wooden torso showing longitudinal sections of the body and the wooden figures showing the number of calories required by workers in various occupations. Such requests are granted when the duplicates are to be used for educational purposes.

The whole collection from the New York Museum of Science and Industry will be transferred to the World's Fair next year. In the meantime plans are being worked out for a future program to utilize the material in the interests of health education. Dr. Bruno Gebhard of Germany, a consultant on health education who has had much to do with the development of the Dresden Hygiene Museum, is now in America on the invitation of The Oberlaender Trust and the American Public Health Association. He is serving as an adviser to these two organizations and to the Committee on Medicine and Public Health of the New York World's Fair, in connection with health exhibits.

THE NEW FEDERAL LAWS RELATING TO FOODS, DRUGS, AND COSMETICS

AFTER five years of consideration,¹ the Congress of the United States has finally adopted two important new laws to amend and strengthen the more or less obsolescent Federal Food and Drug Act of 1906. One of these measures, giving the Federal Trade Commission jurisdiction over false advertising of foods, drugs, devices, and cosmetics, was signed by the President on March 21, 1938, to become effective 60 days from that date; the other measure, a new Federal Food, Drug, and Cosmetic Act, was signed on June 25, 1938, and becomes effective one year from that date, except that several sections, including one (Sec. 701) authorizing the Secretary of Agriculture to hold hearings and promulgate regulations for the enforcement of the act became effective on the date of approval of the law. The Secretary is also authorized to designate prior to the effective date food having common or usual names and exempt such food from the requirement of the act, but only for a reasonable time to permit the formulation, promulgation, and effective application of definitions and standards of identity.

Under the terms of the first law mentioned, which is officially designated as Public—No. 447—75th Congress, and is popularly known as the Wheeler-Lea Act, the jurisdiction of the Federal Trade Commission is extended to the advertising of all foods, drugs, diagnostic and therapeutic devices, and cosmetics (except soap) in interstate and foreign commerce, or through the mails. Whenever the Commission believes that any person, partnership, or corporation is engaged in, or is about to engage in, the dissemination of false advertising, defined as "an advertisement, other than labeling, which is misleading in a material respect," the Commission may bring suit in a federal district court to enjoin the dissemination of the advertisement. If the commodity advertised is injurious to health because of its use in accordance with its advertising, or the advertising is intended to defraud or mislead, the advertiser may be haled to court and prosecuted criminally without previous notice. Ordinarily, however, false advertising is regarded as an unfair or deceptive trade practice, with the advertiser subject to a proceeding by the Commission consisting of notice, a hearing, and, if the findings justify it, the issuance of a cease and desist order, which may

be appealed to a federal circuit court of appeals, and finally to the Supreme Court.

In determining whether an advertisement is false, the law states that there shall be taken into account (among other things) not only representations made or suggested by statement, word, design, device, sound, or any combination thereof, but also the extent to which the advertisement fails to reveal material facts. Advertisements of drugs are not deemed false when disseminated only to the medical profession, provided they disclose the formula and contain no false representation of material facts. Publishers, radio-broadcast licensees, and advertising agencies will not be liable for the false advertising of manufacturers and sellers if they furnish to the Commission on request the name and address of the person responsible for the advertisement.

This somewhat drastic law, if reasonably enforced, should have a salutary effect upon the nature of food, drug, device, and cosmetic advertising in interstate commerce, although it seems likely that the law will give rise to much time consuming litigation. It is also unfortunate that there should have been the division of authority between the Federal Trade Commission and the U. S. Department of Agriculture, which has had and continues to have jurisdiction over the labeling and the adulteration of these same products. Not only is this department equipped by training and experience to carry out the necessary administrative duties, but it has adequate laboratory and technical facilities for the purpose.²

Under the terms of the new Federal Food, Drug, and Cosmetic Act (Public—No. 717—75th Congress), the adulteration or misbranding of any food, drug, diagnostic or therapeutic device, or cosmetic (except soap) in interstate commerce is prohibited. This act not only gives administrative jurisdiction to the Secretary of Agriculture over devices and cosmetics, which were not included in the law of 1906, but it also provides for injunction proceedings in federal district courts to enjoin adulteration and misbranding of foods, drugs, devices, and cosmetic, as well as providing for the customary criminal actions for violations, and for seizures and destruction by court action of dangerous and fraudulent commodities. In order to carry out the purposes of the act, the Secretary of Agriculture is authorized to promulgate necessary regulations.

Since the law is a lengthy one, and it is difficult to review all of its many specific provisions within the limited space of an editorial, it is suggested that health officials and other interested sanitarians secure copies of the act from the U. S. Department of Agriculture, for careful study.

In general, however, it may be stated that the new law contains comprehensive and somewhat broadened definitions of adulteration and misbranding of the various products, so as to include in the former category not only the presence of poisonous or deleterious substances that are injurious to health, but the absence of valuable constituents, the substitution of inferior materials, and, in the case of drugs, substandard quality, purity, or strength. Under misbranding is included not only false and misleading labels, but improper imitations of labels of other products, misleading containers, and in cases of foods for special dietary uses, failure to give information as to vitamin, mineral, and other dietary properties. Special labels are required on drugs containing habit-forming narcotics, with adequate directions for use and suitable warnings on such labels. In the section on cosmetics there is a provision that coal-tar hair dyes must be labelled with a

caution against their use for dyeing eyebrows and eyelashes, and the statement that such use may cause blindness.

An important section of the law requires that new drugs can be introduced in interstate commerce only after filing an application, with submission of evidence and data, and the securing of a permit from the Secretary. Refusal by the Secretary of such a permit may be appealed to the federal courts. If this provision of the law had been in effect a year ago, the series of unfortunate deaths from the use of an elixir of sulfanilamide probably would not have occurred.

The new law does not cover meat and meat food products, which are still subject to the Meat Inspection Act of 1907, as amended. It also keeps in effect various other existing laws, such as the Butter Standards Act of 1923, the Filled Cheese Act of 1896, the Filled Milk Act of 1923, and the Import Milk Act of 1927.

The Federal Food, Drug, and Cosmetic Act of 1938, as sponsored by the late Senator Royal S. Copeland, represents a noteworthy advance over its 32 year old precursor, the Federal Food and Drug Act of 1906, as occasionally but inadequately amended. The enforcement of this law after June 25, 1939, should do much to aid in the protection and promotion of public health in this country.

THE AIRPLANE AND YELLOW FEVER

THE rapid multiplication of airplanes of all types and the tremendous increase in their use for personal transportation has necessarily been a matter of great concern to all nations. A number of reports have been made and efforts are under way to bring about international agreements and methods for inspection of passengers and for disinsectization of the planes. The increase in the use of planes is shown to some extent by a report¹ of the examinations made at Khartoum: 287 in 1935; 667 in 1936; and 364 up to July 2, 1937. Indeed Khartoum is now a modern city and the crossroads for airships coming from many different directions. Its airport is the stopping place for night for all of the great lanes. Apparently this gives an abundance of time for disinsectization and inspection, which requires a longer or shorter time, according to the arrangements of the interior and the number of insects which it is necessary to capture. At least one-half hour is required for inspection. The work of the Custom officers and of the Postal service should be delayed until the planes have been cleared of insects. It is interesting to note that in the Sudan until 1936 the insecticides employed were "Flit" and "Shelltox," widely used in this country, but since then a cheaper mixture made on the spot is used, which has the added advantage of being practically nonflammable.*

Mosquitoes are found chiefly in the compartments occupied by passengers, but also in the baggage compartments, especially in those planes in which these are reached by a separate door at the side. So far no mosquitoes have been

* Extract of pyrethrum..... 5.8 per cent
Essence of citronella..... 2 per cent

Tetrachloride of carbon..... 49 per cent
Kerosene 43.2 per cent

found in the new hydroplanes which have been put in service since April, 1937. For over 3 years, only 3.5 per cent of planes examined at Khartoum have harbored mosquitoes. Of these, 79 per cent are those coming from the East. The great majority of mosquitoes found so far have been *Culex* and only 10 *Anopheles*.

An elaborate report² covers the sanitary conditions of airplane navigation in the French Colonies and Mandates. So far everything has gone remarkably well, in spite of the fact that the international agreement of April, 1933, has not been ratified by France and consequently not promulgated in her Colonies. Most of the airports of the French Colonies are in regions where yellow fever has been known or is quiescent, and in which there should be provisions to protect against the disease. It is pointed out that there are considerable areas of dispersion of yellow fever virus in South America and in Africa, and great possibilities of spread if there is introduction of carriers or the insect vector by airplanes.

Vaccination against yellow fever seems to be the ideal, but so far it is inapplicable to those populations living in these areas. It is held that in order to give complete security it should be carried out in laboratories, be controlled frequently, and revaccination done where the tests show insufficient protection. Such conditions are not applicable to masses.

One has only to look over the various airplane routes as summarized by Inspector Sorel to realize the possibilities of spread of disease by planes. The French use four great lanes in common with several other countries in reaching their colonies and mandates. Joining these great highways are sidelines, practically all of which connect with areas in which yellow fever might exist.

America³ is not at all free from some of the dangers due to rapid travel by airplanes. Our Public Health Service is represented in the International Office of Public Hygiene, and has always been awake to the situation. At Miami, steps have been taken to guard against the importation of the *Aedes aegypti*, and researches are being made on better methods for disinfection of airplanes. A special corps is being instructed to study the *Aedes aegypti* in the cities of the South, and it is held that no airport of entry should be established within 20 miles of a city which shows a high index for *Aedes*.

In August, 1937, a living *Anopheles maculipennis* was found in a Chinese Clipper arriving at Honolulu from Alameda, Calif. Hence, instructions have been given to the Pan-American Airways and to the Medical Officer of the Quarantine Station at San Francisco that a complete fumigation be done at departure by an operative of the Service.

The constant travel of passengers from the United States to South America and back again, which can take place within a week, shows the necessity of the greatest care in our contacts with those of our neighbors on the South within whose borders yellow fever is found.

The greatest menace in the world today, and perhaps the one which is being thought of most, is the possible infection of India by yellow fever. The climate is suitable and apparently all it needs is the introduction of the virus. There we have several hundred million people who have never been exposed to yellow fever, who exist on a low plane of living, and who, as far as we can judge, would be very susceptible to the disease, yet planes of the Imperial Airways have flown from the Sudan to India in less than 48 hours.

We have been forced to abandon the "simple man-*Aedes aegypti*-man epi-

demology," though it still yields perfect results in many areas. The virus of yellow fever has been transmitted in the laboratory by several species of mosquitoes found in Africa and South America other than the *Aedes aegypti*, and, in 1935, we were shocked by the discovery of "Jungle Yellow Fever," perhaps the natural and more permanent form of the disease.⁴

Aedes from both Egypt and India have been found susceptible to laboratory infection. Opportunities for the introduction of yellow fever into India certainly exist, and are multiplying constantly.

This imperfect sketch founded on an elaborate report by experts must demonstrate to everyone the necessity of international coöperation in the establishment of airports, their freedom from mosquitoes known to carry disease, the regulations concerning passengers, the disinfection of airplanes, etc. All of this applies with double force to airports of entry.

NEW LIGHT ON OLD BELIEFS

THE announcement of the discovery of the tubercle bacillus in 1882 was followed immediately by experimental studies of various sorts, notable among which were those of two of the great scientists of the veterinary profession.¹ Nocard in France and Bernard Bang in Copenhagen, reported respectively at the first Congress on Tuberculosis in 1888, and the Congress of Hygiene, 1891. Both were concerned with the possible danger of the transmission of tuberculosis to human beings by eating the flesh of tuberculous cattle.

Nocard injected large quantities of tubercle bacillus into the veins of cattle. Within a few hours, the blood was absolutely free from the germs which had been introduced. In a few days, the many organisms which had been caught in the muscles had been destroyed or, as he said, at least put in such a condition as to be of no danger—they had lost their power of multiplication as well as their virulence. Bang drew blood from twenty cows with advanced tuberculosis and after defibrination, injected it into the peritoneal cavities of 38 rabbits and 2 guinea pigs in doses of from 10 to 18 c.c. Only two of the inoculated animals showed positive results and the cow whose blood had proved virulent was affected by an acute miliary tuberculosis following an injection of tuberculin.

Without discussing further the many experiments which have been done, it may be said that as early as 1883 experiments had shown that in the immense majority of cases, the danger of infection was confined entirely to the tuberculous lesions and that the blood and the juice from the muscles in particular only exceptionally carried tubercle bacilli.

It has, of course, been recognized for many years that in probably every case of tuberculosis in cattle which went on to death, there are moments when through the disruption of a tubercle, germs are thrown directly into the blood, but, as in the experiments quoted above, the blood rapidly gets rid of the germs which have been thrown into it.

This has been the teaching for many years and the results have proved the practical correctness of the experimental findings.

Recently (1936) studies have been brought forward which must lead to some revision of our views. Nieberle² has investigated the pathogenesis of those forms of cattle tuberculosis in which there is fresh, dry, infiltrating caseation, a good example of which is what he calls "mastitis caseosa." In these cases, the udder shows large areas of caseation surrounded by an area of hyperemia and an infiltration extending widely. Sections show tubercle bacilli in large numbers at the periphery and they enter the damaged blood vessels readily. A tuberculous "bacillemia" is demonstrable under the microscope, corresponding to that which has been mentioned as occurring in advanced cases. Similar changes occur in the lymph nodes and, like the lesions in the udder, may liberate enormous numbers of the bacilli into the general circulation. In 13 such cases, tubercle bacilli were found in the meat. The author calls attention to the fact that just such changes occur in rapidly caseating lobular pneumonia in cattle. In 18 of 21 such cases, examination of the meat showed the presence of tubercle bacilli, and similar results have been obtained in caseating tuberculosis of the adrenals, kidneys, uterus, ovaries and serous membranes.

In summary, tubercle bacilli were found in the meat in 69 of 82 cases. Both cultural and animal inoculation were positive in 26 cases, animal inoculation alone in 39, and cultural examination alone in 4. In every case, the bovine type of organism was found.

In discussing the importance of these findings, Nieberle says that there are 2 main types of tuberculosis in which occur what he calls "fresh blood infection": (a) miliary tuberculosis in children; (b) acute miliary tuberculosis in adults. In children, generalization occurs from a primary focus which is often easily found, while in adults, it is seldom demonstrated. Both of these types are, however, found in cattle, and in 15 of 23 cases, representative of both of these types, tubercle bacilli were found in the meat by bacteriological examination. When the generalization occurs late in the disease, the lymph nodes are not often involved. When it occurs early, they invariably show tuberculous changes.

Nieberle insists that in examination of meat for tuberculosis, the qualitative character of the tuberculous lesions should be more carefully studied, and he considers this point more important than the quantitative distribution. For example, a small area of dry caseation with marginal hyperemia is more important from the health standpoint than widely distributed lesions of a productive nature, owing to the fact that the former is able to give rise to what he has termed the "fresh blood infection." He holds that the whole idea that tuberculosis of the related lymph nodes indicated tuberculosis of the muscles and of the bone-marrow is incorrect, and the latter can arise only from hematogenous infection and indicates a tuberculous "bacillemia."

However, the greatest protection for the human race lies in proper cooking. Only where such meat is eaten under-done or raw as in tartar sandwiches does danger exist. No doubt more careful inspection along the lines indicated will be of advantage, but even accepting the new findings, as we do, we doubt if the danger to human health is extremely acute. We again emphasize, however, the great protection of proper cooking.

SAMUEL M. CRESWELL

WORD has just been received of the untimely death of one of Tacoma's finest and most useful citizens and one of the most promising young physicians in the field of public health administration. Dr. Creswell, who has served as Health Officer for Tacoma with a remarkable record of accomplishment which has attracted national attention, was killed in an automobile accident just outside of Seattle. This tragedy is a new bit of evidence of the peril which stalks our crowded highways. A truck made a sudden turn across the highway and into it plunged the vehicle in which Dr. Creswell was a passenger.

American public health loses a promising pupil. A fatality is a deep tragedy to the household and in this case should stir to action the thinking minds in public health and health education who too complacently observe the ever increasing death rate due to automobile accidents. Forty thousand lives in a single year snuffed out by this preventable cause. In 1937 typhoid fever in 93 American cities with a population of 38,885,435, claimed but 318 victims. In the same year in these cities there were but 568 deaths from diphtheria. How insignificant are these figures when compared with death on the highway.

While it is not suggested that health officers become highway patrolmen, it is incumbent upon public health administrators to assume a leading rôle in the conservation of human life, whatever be the immediate cause of death. Recognition of the numerical importance of deaths from accidents is evidenced by the inclusion of this item in the schedule of the annual health conservation contests. May we suggest Dr. Creswell's untimely death as a circumstance about which to construct a program of public education.

In 1933 Tacoma was awarded a free survey by the American Public Health Association. At that time this city ranked twenty-third in its health rating among American cities. It will ever be a credit to Dr. Creswell's memory that within a few years Tacoma appeared among the cities of honorable mention, and in 1937 was awarded first place for its syphilis program—first on the list among all the American cities to enter this, the first, of the syphilis contests.

To Mrs. Creswell and her two daughters the American Public Health Association extends its heartfelt sympathy. To the public health profession may we express the hope that Dr. Creswell may not have died in vain. Human sacrifice to the whims of the careless driver should be eliminated.

PUBLIC HEALTH EDUCATION*

Again in October—Health education will have its full share of time and attention in the 1938 Annual Meeting of the A.P.H.A. in Kansas City.

There will be regular sessions, luncheons, and a dinner meeting.

There will be an extensive headquarters with a fine new line of health educational materials, and the opportunities for individual and group consultation.

There will be the ever recurring and frequently valuable lobby sessions.

There will be a bigger and better display of scientific exhibits.

There will be an hour by hour showing of motion pictures.

Because of the abundant space, we welcome at headquarters demonstrations and displays not possible in New York.

Now is the time to start planning that you may be more sure of getting to Kansas City.

"Fairy Tales and Neuroses"—Under this heading *Health News* of New York State Dept. of Health (March 7, 1938) discusses a *London Times* editorial on the supposed unsuitability of many fairy tales for the child audience. It all grew out of objections to the "horror" scenes in "Snow White and the Seven Dwarfs."

Our contribution to the discussion is a report on the fears of a 5 year old boy and a 7 year old girl. A friend had taken the children to see "Snow White." After reporting on the picture

to their mother, a slight, somewhat tiny person, she expressed a desire to see the picture. "But Mother, you must not go. You would be scared. You are too small."

A State Helps the Locals—The New Jersey Tuberculosis League, 15 E. Kinney St., Newark, accompanies the weekly issue of its *News* with ready made press material prepared for easy localization.

At the present time this takes the form of "Story of the Week," the reproduction of a recent local news story, with blank spaces in which local facts or statistics may be filled in by any other county organization.

A recent story titled, "N. J. Clinics File Report," based on clippings received from Ocean and Cumberland Counties. Here is the copy as sent out on a single mimeographed letter size sheet:

New patients attending tuberculosis clinics in the state during 1937 totaled 19,657, according to an annual report released recently by the New Jersey Tuberculosis League and forwarded to the (organization). County had new cases. The statistics are compiled with the cooperation of the State Department of Institutions and Agencies and the New Jersey Department of Health.

Of those attending clinics last year in County per cent were diagnosed as having tuberculosis, per cent were non-tuberculous, and per cent were listed for observation. The last group included childhood type tuberculosis, contact cases among children and adults, and children who would not immediately be diagnosed and who are kept as active clinic cases because of physical or clinical signs.

The death rate from tuberculosis last year was 48.1 per 100,000 for the state.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

..... County's rate was There were deaths from tuberculosis in County during 1937, of whom were Negroes. New cases of tuberculosis reported to the State Health Department were of which number were reported from (organization) chest clinics. According to the report school children were tuberculin tested in the schools of County, were positive.

..... holds its last clinic for the summer season (date). Attending a chest clinic does not mean that any individual necessarily has tuberculosis; on the contrary it is one of the best ways of finding the person does not have it.

When Addressing Mail—If you wish to reach a particular individual in any organization it is the safer plan to note his title or his name *above the name of the organization*.

If you wish to label a letter as "personal" or "confidential," or to request that it be forwarded or not forwarded, it is by far the safer plan to *make the notation above the remainder of the address*.

In many cases if such special instructions are written in the lower left corner they are overlooked in the handling of quantities of incoming mail.

Grammar for Writers—May Lamberton Becker, "The Reader's Guide" of *New York Herald Tribune Books* (every Sunday), is wise and widely informed on the choice of books. A correspondent

... asks for books on English grammar and composition that will answer almost any question that may come up in preparing copy for the printer.

Here is Mrs. Becker's reply:

This inquirer already owns *A Manual of Style* (University of Chicago Press), the *New Handbook of Composition*, by Edwin C. Woolley (Heath), a useful book of reference in correcting technical errors; and the *Advanced English Grammar* of G. L. Kittredge and Frank E. Farley (Ginn); for dictionaries he has *Webster's New International* (Merriam) and the *Shorter Oxford English*

Dictionary, two volumes (Oxford University Press). Make a note of these; they are well worth putting into a permanent reference library of this sort, and indeed form one by themselves.

For additions to this I suggest as a beginning a new book expressly for people who are inexperienced in sending stuff to the printer and will find this practical for that purpose: *Manuscript and Proof*, by John Benbow (Oxford University Press). I know printers who swear by the *Authors' and Printers' Dictionary* (Oxford) of F. H. Collins, a little book to help proofreaders and others, with a full list of abbreviations. Another brief book with much in it, just out, is H. A. Treble's *A B C of English Usage* (Oxford). Even smaller than this is the *Author's Book* Macmillan issues for 50 cents: this is packed with sound information, one of the elementary kind needed by most people beginning to send out manuscripts. I don't see how the list of dictionaries this inquirer already has could be bettered, but such a library is not complete without the provocative *Modern English Usage* of H. W. Fowler (Oxford). Its immediate effect is to put one into the state of the centipede who debated which foot came first; Fowler makes a mistake seem so awful that you stop writing for fear you may make one. As you rapidly come back on the rebound, ready to fight the King's English single minded, the result is all to the good.

Why Not More about National Agency Publications? — We agree heartily that more about the aids and publications offered by national agencies should be given in these pages. We realize that only a limited audience actually learns of new publications, posters, slides, and other materials issued by the nationals. It is economically impossible for the nationals to mail announcements to all who might be concerned.

Moreover, even to reach those most directly interested, more than a single approach is needed. Long and careful observation shows that many important service announcements are lost after delivery by mail. In all too many state and local agencies distribution or circulation of service information among staff members is inadequate. And fre-

quently the printed or mimeographed statements are so small or inconspicuous in appearance that they are neglected.

Furthermore, various staff members of state or local agencies have an interest in health educational materials even though their primary job is in another technical field. Among the staff members of agencies, nationals in all health fields, state and locals, are the people who answer letters, who meet people in their offices or in field visits, who are asked about health education. Neither health workers nor lay readers are discriminating when looking for information. Whoever they happen to write to, or whoever they are accustomed to address for information or advice on other specialties are likely to be asked about health education materials. For example, even the New York correspondents of local banks are sometimes requested to get information for use in Keokuk or Kalamazoo.

Then outside there is a vast unnumbered audience of people who want to help in one way or another, or who might help. Among these are people who write for periodicals, students in schools and colleges, leaders in all the varied non-health groups which do something in health education. They go to libraries, they may call on local health workers, they write to women's magazines and to various people in the larger cities.

These paragraphs lead to two suggestions. The first is that health workers generally keep in reasonable touch with the whole field of health, the health education programs for the various special fields, and the sources and nature of available health education materials. The more we all help to play the other fellow's game, the stronger all will be.

The second suggestion is that the national agencies and other national

sources of health education materials help this department to make a continuing and fairly complete record of all new material. The *Journal* is to be found in so many public, college, and school libraries, and of course in the offices of state and local health agencies. With full coöperation in recording new materials we have at least one fairly permanent source of information available at one or a number of places in every sizable community.

It seems to be up to the nationals to make this service all that it might be.

A periodic checking of mailing lists is important. Not to cut out waste addresses, but to insure the inclusion of useful addresses. Our experience is that such addresses do get lost from mailing lists.

Many Pictures—Some Words—
See 88 story telling pictures, accompanied by a "sound track" of 88 pages, each with a line of text or several lines, as may be needed. In *Land of the Free*, by Archibald MacLeish. Harcourt, Brace and Co., New York, N. Y.

A poet weaves pictures and words into a tapestry picturing thoughts and lives of many people.

STATE TB. BULLETINS

Michigan's *Health*, with a fairly "modern" layout of its 2 outside pages, gives the last page to an "editorial" (with no capital letters).

New Jersey's *N.J.T.L. News*, in its weekly one legal cap page (printed stock heading) carries news from the counties and announcements of plans and helps, usually in paragraphs less than 6 lines long.

The most intimate of all the trusted house organs is *Flashes*, a mimeographed issue of the New York State Health Committee on Tuberculosis which enters the hands of the organization in the way of

hunches for the every day jobs of city and county workers.

Ohio Public Health gives most of its first cover page to a well displayed quotation. One from Osler in June, 1938.

Wisconsin's *Crusader* "Questions and Answers" column prompts a query as to why this feature is not more common.

MAGAZINE ARTICLES

See "Why 'Magazine Articles'?" on another page to learn some of the reasons for publishing this partial list of articles on health topics.

"To my unborn Son," by T. Sucrue. *American Magazine*, 250 Park Ave., New York, N. Y. Jan., 1938. 25 cents. A letter from a father picturing contrasts between childhood conditions of the father from those of the expected son, as to health and otherwise. An interesting device.

"Becoming a Mother Is Too Often a Needless Rendezvous With Death," by Hazel Corbin; picture of a father's clinic class; "Mobilization for New York's Battle Against Syphilis," by Dr. Thoe. Rosenthal; "Account Payable on Presentation," by Jacob Goldberg (venereal disease costs). *Better Times*, 44 E. 23d St., New York, N. Y. June 6, 1938. 35 cents. Many illus.

"Japan Invades China With Drugs," by M. Lester. *Christian Century*, 440 S. Dearborn St., Chicago, Ill. May 11, 1938. 15 cents. How the drug traffic is being fostered!

"Feet First," by H. Lees. *Collier's*. June 25, 1938. Care of the feet.

"Key to Lockjaw," by J. D. Ratcliff. *Collier's*. July 9, 1938. Services made possible by the "biological-laboratory" horses; how serum is produced and distributed.

"Looking You in the Eye," by H. Lees. *Collier's*. June 11, 1938. How the eye works; what may go wrong. "Fascinating gadget, the eye."

"Make Safety Pay," by D. Lindley.

Collier's. March 26, 1938. "You can't scare people into taking care of themselves on the highway. Why not try offering a reward?" Rochester's answer is described.

"That Child's a Problem," by L. McCorky. *Collier's*. May 21, 1938. "But he needn't be." Here is the answer.

"Death to Food Fallacies." *Consumers' Guide*, Dept. of Agriculture, Washington, D. C. Nov. 29, 1937. "Here are a few false, foolish, or half-true ideas about nutrition to unload from your pack of prejudices."

"The Healing Knife," by George Sava. *Cosmopolitan*, 57th and 8th Ave., New York, N. Y. July, 1938. 25 cents. Autobiography of an anonymous surgeon.

"Mellon Institute Is Scientific Cradle of Industrial Discoveries: Its scientists now turn to fight widespread and dreaded silicosis." 2 pages. *Life*, 330 E. 22d St., Chicago, Ill. May 9, 1938. 10 cents.

"A motorist's nightmare," depicted by Rockwell Kent (1 page); "The Traffic Problem: Its Best Solution Lies in Foolproof Highways" (1 page); "After 100 Years American Roads Are Only Half as Fast as the Cars Traveling on Them" (2 page picture diagram); "Traffic" (2 pages showing types of accidents and the people who cause them); 6 pages of safer streets and highways. *Life*. July 4, 1938.

"From Stout to Slim." *Look*, Des Moines, Ia. May 24, 1938. 10 cents. 2 pages of famed reducers: Hutton, Talley, Whiteman, etc.

"If You Take It Easy, You Can Enjoy Life after 50: A Health Guide for the Middle-Aged," by Dr. Morris Fishbein. 2 pages of pictures good to be made up into an illustrated folder. *Look*. June 21, 1938. Also "What Are Your Chances for a Happy Marriage?" Includes:

"6. Are You Preparing Yourself for Mar-

riage (or have you already done so) by reading carefully at least two good books on marriage? (Three points.)"

"By discussing marriage problems with your family doctor or some well informed persons other than your parents? (Two.)"

"Doing nothing to inform yourself about marriage? (One point.)"

These two pages suggest a new form of presentation quite unlike typical, sometimes stodgy, health advice printed matter.

"Young Britain Learns the Perils of Auto Traffic" (a page of teaching devices); "Your Feet . . . Things You Should Know about Them" (2 pages); "The Folly of Fireworks" (2 pages); "Bernarr Macfadden: Building Bodies Built His Millions" (2 pages); "What Happens when You Sit in a Draft" (1 page); "How to Stay as Slender as You Are" (2 pages). *Look*. July 5, 1938.

"Science Helps the Police Detect Drunken Drivers" (2 pages); "Plastic Surgery" (3 pages). *Look*. Aug. 16, 1938.

"They're Not Playing Today" (children injured by automobiles); "They Breathe Their Medicine" (new facilities for medication by nose and throat). *Look*. Aug. 2, 1938.

"Medicine's Misalliance," by James Rorty. *Nation*, 20 Vesey St., New York, N. Y. June 11, 1938. 15 cents. Reviews various manifestations of "medical care" turmoil in and out of A.M.A.

"The Health of the People: What Social Workers Should Do about It," by John A. Kingsbury. *Social Work Today*, 6 E. 46th St., New York, N. Y. June, 1938. 15 cents.

"My Back Is Killing Me," by Maxine Davis. *Pictorial Review*, 57th and 8th Ave., New York, N. Y. July, 1938. 10 cents. "Backaches—what brings them on, how to prevent them, what to do when we have them." Also "Hypersensitive or Allergic Children," by Drs. Fishbein.

"The Miracle of the Iron Lung," by

T. Mahoney. *Rotarian*, 35 E. Wacker Drive, Chicago, Ill. July, 1938. 25 cents.

"Little Doc," by Frazier Hunt. *Saturday Evening Post*. April 23, May 7, May 14, May 21, May 28, 1938. The life story of Dr. Dafoe.

"Yellow Jack Breaks Jail," by Victor G. Heiser, M.D. *Saturday Evening Post*. May 21, 1938. Yellow fever, from early New Orleans, today, and in the future.

"I Saw a Resurrection," by M. Kienast. *Saturday Evening Post*, July 2, 1938.

Why "Magazine Articles"?—Why give space for lists of articles on health topics to be found in current general and special magazines? Because we have an idea that the material will be useful both inside and outside the health department or association.

"What do you think of that article in such and such magazine?" is a question put to many health workers. The lists help to anticipate that question. A group of staff members might report on different articles. Notes as to errors or good qualities of the articles could be attached to copies placed in reference files or in the public loose leaf collection.

What *Collier's* or *Saturday Evening Post*, *Life*, or *Look* says to many people has a significance all of its own. So that it seems worth publicizing such articles in several ways: listing on the bulletin board . . . noting in the house organ . . . distributing mimeographed lists to the staff . . . making lists available to any who may ask for them . . . supplying lists to teachers, many of whom will be glad to learn of especially good articles, and will wish to know what articles can be trusted . . . bringing to the attention of staff members articles which contain good talking points on subjects which enter into the current program of the organization.

Other uses of the listed material include reprinting of some articles for health agencies, or by them. More reprinting of articles and picture pages might be done to advantage.

The magazine material carries suggestions for health education. The topics or the titles may help. The types of pictures, and ways they are used may suggest how some of our own material can be put up to look less like health "education." (Remember what many people think of "educational" motion pictures, and "educational" radio programs.)

STATE DEPARTMENT BULLETINS

Arizona Public Health News carries this statement on its front page:

"The Welfare of the People is the Supreme Law."

Connecticut Health Bulletin (June, 1938) listed "reference books of value to persons doing laboratory work on water and sewage samples," and

"Current scientific journals which contain more up-to-the-minute information of value to persons making laboratory examinations than do text books or reference books."

Connecticut Health Bulletin once a year carries one leaf, scored for easy tearing out, which says:

"If you wish your name to be retained on the mailing list for the Monthly Health Bulletin please sign on reverse side, tear off this page, return at once." (We wonder how many of these sheets are returned?)

Florida Health News carries on its

back page a silhouette map of the state with this message:

Watch This Map: it denotes the progress of County Health work in Florida. Each white dot stands for a full-time county unit."

Indiana's *Monthly Bulletin* runs cartoons, with a dozen or fewer words of conversation, headed "Uncle Doc."

"New Activities of the Massachusetts Dept. of Public Health" is the theme of the Jan.-Mar., 1938, issue of *The Commonwealth*, Massachusetts Dept. of Public Health. The 86 pages include the Division of Adult Hygiene, Postgraduate Extension Courses, Training of Lay Readers, New Materials in Health Education, etc.

A weekly feature of *New York State Health News* is a shrewd, folksy monologue headed "'Dr. Jones' Says—."

Ohio Health News makes good use of carefully selected quotations in addition to good original matter. Ohio may attempt to crowd too much good copy into the 4 weekly pages. The small type makes it look a bit heavy to the reader.

Oregon's *Weekly Bulletin* and North Carolina's *Health Bulletin* are among the state bulletins which publish book reviews. A good idea for wider use?

The *Wisconsin State Board of Health Bulletin* frequently reprints health editorials from newspapers and other periodicals. Under "With the Wisconsin Editors" more space is given to such material than in any other state house organ.

BOOKS AND REPORTS

Occupational Disease Symposium—*Chicago: Northwestern University Medical School*, 1938. Planograph copy, 86 pp., paper cover.

This symposium was held September 27-28, 1937, in Chicago, and followed recognition by Northwestern University of the increasing prominence which industrial disease has come to occupy in the field of general medicine. The university established its department in this field in 1936. Full facilities were placed at its disposal, with arrangements for presenting findings to the medical officers of interested industries.

Exhibits were shown by the Chicago Municipal Tuberculosis Sanatorium as well as a shadow-box display of nearly 60 chest roentgenograms by Dr. Hollis Potter. Dean Irving S. Cutter acted as general chairman. The papers presented concerned: "The Rôle of Allergy in Industry," by Dr. Samuel M. Feinberg; "The Rôle of Allergy in Industrial Dermatoses," by Dr. Marion B. Sulzberger; "The Healthy Chest and the Modifying Influences of Silicosis and Silicosis with Infection," by Dr. Eugene P. Pendergrass; "Some Phases of the Pathology of Silicosis," by Dr. Leroy U. Gardner; "Industrial Solvent Exposures and Their Control," by Warren A. Cook; "Some Recent Developments in the Field of Industrial Solvents," by Dr. Alice Hamilton; and "Industrial Lead Poisoning," by Dr. Robert A. Kehoe.

The banquet session provided Introductory Remarks by Dean Cutter, a paper on "The Prevention of Occupational Disease," by B. C. Heacock, and a closing paper on "The Future of

Industrial Medicine," by Dr. Morris Fishbein.

The titles of the papers, and the prominence of the names of the authors give ample evidence of their importance and authoritative sources. Many interesting points are contained in the discussions. Several of the papers are followed by bibliographies. The proceedings of this symposium form one of the most recent comprehensive collections, and should be of interest to physicians and industrial establishments as well as to hygienists in general.

EMERY R. HAYHURST

Life and a Living—*By Committee for the Care of the Jewish Tuberculous, Inc. New York: Altro Work Shops, Inc.*, 1937. 65 pp. Price, \$.35, paper, \$.50, cloth.

With a preface by Dr. Kendall Emerson and a concluding address by Louis I. Dublin, Ph.D., on the occasion of the 21st anniversary of the Altro Work Shops, Part I is devoted to the "Cure" of Tuberculosis, and Part II, to Industrial Convalescence. There are a number of photographs and charts.

The basic concept of the Altro Work Shops is that medical care of the tuberculous can be effective and enduring only when it combines social work at the sanatorium, care of the family in the home, and intensive care after discharge, which must, of course, include a rehabilitation program. It is essentially an industrial rehabilitation program. Instead of the age-old advice, "find some light outdoor job" (which jobs are practically nonexistent), the plan has been to place

the worker in the Altro Shops under close medical supervision which permits activity correlated with safety to the worker and his surroundings. The plan is in some respects similar to the Papworth Village Settlement, Cambridge, England, which has been so ably promoted by Sir Pendrill Varrier-Jones for a number of years.

The Altro Shops have served 10,000 patients and their families in the 23 years to 1936. This report reviews the organization of the original committee, the clinics, the difficult adjustments necessary, and the plan of financing. A city garment work-shop in place of industrial farm colonies was decided upon. Patients came from many occupations but were trained by expert garment makers. The shops turned out more than 500,000 shirts at contract rates for the U. S. Navy during the war. The output is sold on value and not on sentiment. At present, hospital orders represent about 69 per cent of the business, hotels and restaurants 18 per cent, industry and others 13 per cent. High piece-rates are paid.

A two story brick building with a sun roof, especially designed for the purpose, accommodates 135 patients. It contains many labor-saving devices and represents a total investment in land and building of about \$190,000; in equipment and stock of \$83,000; and clear assets of \$81,000. Will Irwin once remarked that Altro was the only place he knew that used a time-clock to keep people from working. All patients are expected to stay at the shop the full day and not to work elsewhere. Vacations are granted and everything possible is done to restore the tuberculous to health. Many return to their former trades. While some must remain for years, others are "cured" in a few months' time. One chart shows that, of earlier patients, 41 per cent were well and working 10 to 20 years after discharge; another, 80 per cent

after 6 months to 10 years. Many originally had positive sputums. During 21½ years patients earned in wages an aggregate of \$1,472,000. Many other interesting data are given. As Dublin says in his address, "The results speak for themselves."

EMERY R. HAYHURST

Teaching for Health—By *Marguerite M. Hussey, Ph.D.* New York: New York University Bookstore, 1938. 312 pp. Price, \$2.75.

This book considers primarily the conduct of the program of public education in such a way as to provide healthful experiences for the child and the application of the principles of general education to instruction in the field of health.

Following a discussion of the historical approach in the development of health education methods, and definitions of health, health education, and health objectives, one finds such titles as: Leadership Organization of the Activities Program for Health, Studying Out-of-School Life, Studying School Life, Studying the Individual, Home-School Coöperation, Technical Teaching, and Printed Materials. There is a brief chapter on the measurement of results and one on units in teaching for health.

The book contains an extensive argument for putting junior and senior high school health teaching in the hands of the teacher of physical education together with a very brief consideration of the other possibilities. The author warns against too extensive injection of health content into tool subjects and dangers which exist in using dramatization, modelling, drawing, and other activities to motivate health practices. She emphasizes the importance of basing health instruction upon the immediate health needs of the pupil, but says little about the relationship of health education to the essential public health

needs of the community. The author considers methods at all levels of education, but there is, perhaps, somewhat more emphasis upon the secondary than upon the elementary or college level.

The book is interestingly written, particularly those phases which have to do with the healthful conduct of general education and the needs of the individual child. Perhaps the reader may differ slightly with some of the generalizations such as: "Good health enables the octogenarian to get as much zest out of life as the adolescent," "All this means that the school must be responsible for the health education of the home as well as of the learner . . ." "The person with varied interests is the happy person, the contented person," . . . "Ideally, there should be a bowel movement after every meal . . ." These disagreements will not be serious, however, and the book is interesting and useful.

C. E. TURNER

Disease and the Man—By Roger F. Lapham, A.B., M.D. New York: Oxford University Press, 1937. 143 pp. Price, \$2.00.

The author views with alarm the apparently persistent swing of the physician's pendulum toward science at the cost of leaving the patient as a human being too much out of the dual equation. In the good old days the family physician had very few scientific crutches on which to hobble along toward the cure of disease, but he was compelled to know a great deal about his patient. In present-day practice of medicine the physician is under such constant strain to keep up with the advances of his profession scientifically that he is prone to neglect the human beings who constitute his clientele as such.

The book is an attempt to get the pendulum to swing back in reasonable measure toward the patient. The wise

physician, and by implication, the one who more than makes both ends meet, has the happy faculty of steering satisfactorily between the entities disease and patient. Six of the 12 chapters of the book elucidate technics on how the physician may capture, hold, and direct the patient while curing the disease.

This is a book primarily useful to medical students, teachers in medical schools, to physicians who may feel themselves a bit weak in blending human relations with science in medicine. It sticks to the subject of how to better private practice. It has not a single paragraph on the burning questions of the hour, "state medicine," "socialized medicine," "medical trade unions," etc.

W. W. PETER

Modern Ways With Babies—By Elizabeth B. Hurlock, Ph.D. Philadelphia: Lippincott, 1937. 347 pp. Price, \$2.50.

The first three years of life are included within the scope of this readable and comprehensive book. Its purpose is said to be "to bridge the gap between the scientific investigator and the parent." In this it succeeds quite well.

All books on the care of babies of necessity deal with about the same subjects, though with varying emphasis. This one, as might be expected from the fact that the author is a psychologist, is at its best in the chapters having to do with the baby's problems in acquiring good habits and emotional control. The need of incentive and opportunity is stressed wisely and more fully than is usually done. Especially interesting chapters are devoted to babyhood emotions, intellectual growth, becoming socialized, and discipline. The book ends with a discussion of personality.

There is a good list of suggested readings and an apparently adequate index.

On the whole, this is an excellent

common sense aid to the intelligent mother, sufficiently detailed and resourceful without any irritating dogmatism. MERRILL E. CHAMPION

Atlas of Skeletal Maturation (Hand)—By T. Wingate Todd and Associates (1926–1936). St. Louis: Mosby, 1937. 202 pp. Price, \$7.50.

In opening this interesting volume the reviewer is impressed immediately with its quality as to selection of paper, type, arrangement of material, and excellent illustrations. It is easy to see even upon casual examination that an enormous amount of work has gone into the production of this volume. Dr. Todd gives due credit to a host of colleagues and assistants who have collaborated with him over the past 10 years in making this study possible.

The skeletal maturation of the hand is illustrated by a large number of roentgenographic plates set up as "standards." Each plate is thoroughly documented with explanatory notes, and references are given to basic material. The whole presentation is highly technical and must be interpreted in terms of the standards and technics laid down in the introductory chapter on maturation. One is struck with the magnitude of the undertaking and the difficulties inherent in the interpretation of such a large mass of data with so many variables.

The book is the outcome of studies which have been frankly experimental from the beginning. The selection of the group of children, the working out of technics, the statistical handling of material, and the final establishing of standards for comparison are unique.

It should be noted that the investigators have submitted themselves to a great deal of self criticism in the attempt to harmonize subjective and objective data. Standards have been arrived at by considerable sifting of material. The anatomical descriptions

may be accepted as they stand as the work of a competent anatomist. Where Todd and his collaborators have challenged the traditional viewpoint on growth, development, and maturation is in the interpretation of their roentgenographic records as "standards" of maturation in relation to health fluctuations of the individual. It is to be desired that others equipped to carry on similar investigations will adopt tentatively the standards laid down in this atlas to determine if other series of measurements confirm the conclusions reached by the author of this intriguing volume.

Abt in his *System of Pediatrics* has pointed out that Thomas Morgan Rotch as early as 1907–1910 called attention to the value of the roentgen rays in delineating the "small bones of the wrist as a basis for an anatomical index of growth in relation to the 'somatic' as opposed to the 'chronological' age of the child." Todd and his collaborators have carried this forward in differentiating growth and maturation and in indicating the factors which enter into the maturation process, thus affording a basis upon which better standards may be erected. RICHARD A. BOLT

Mental Hygiene for Nurses—By Elizabeth Lee Vincent, Ph.D. Philadelphia: Saunders, 1938. 263 pp. Price, \$2.00.

The increasing emphasis on mental hygiene and the appreciation of the value of mental hygiene principles have been calling for the publication of just such a book as this and that it should have been done so readably and so authoritatively in non-technical language should make it a "must" book for every nursing library and for every nurse.

It would be difficult to select one chapter or section for special commendation as the same high standard is maintained throughout.

As indicated by the chapter headings a large part of the book is applicable to all young people, whether student nurses or students in any other educational course as well as to young people whose student days may have ended. Being addressed particularly to nurses, however, it is unlikely to be read by many other student groups much as it is desired to place such a book as this in the hands of all students in our educational institutions.

The value of the book is enhanced by the questions for study and discussion at the end of each chapter, most of which require the student to consider her own problems, attitudes, and reactions.

A carefully selected bibliography suitable for nurses and students generally is appended to each chapter and a complete index is also provided. A thoroughly excellent and exceedingly useful book. G. H. STEVENSON

Les Epidemies et l'Histoire—By Albert Colnat. Paris: Editions Hippocrate, 7, rue des Grands-Degres, 1937. 191 pp. Price, \$1.35.

The author begins with a few well considered remarks on the influence that microorganisms of disease have had on history. Especially have epidemics left their mark. The suddenness, extent, and violence, with the sense of helplessness which they evoke in a stricken community, lead to the most extravagant and unreasonable actions. Even today there are those who regard them as the vengeance of an offended God.

The great epidemics of the past are reviewed in order, beginning with those which afflicted the Jews and are told of in the Bible; next those of the Roman Empire are considered, and, after that, those of the Middle Ages. In this section particularly we have a good description of the rat and its dangers, also the Hundred Year War, with its

direful effects. The fourth section deals with modern times. The author describes the discovery of America and the pandemic of syphilis. He credits to the Spanish historians the idea that the disease was carried to Europe by the sailors of Columbus who had contracted it in Haiti. The fifth section considers the wars in which Napoleon took part, and introduces to us Baron Larrey. The last section brings us to the present day and considers the epidemics of the World War.

The author calls attention to the fact that this struggle brought into practice many of the best discoveries in military hygiene. The confidence of the soldier in the Medical Department grew greatly. On the one hand he was sustained in battle by his patriotism and his confidence in the precision of modern arms; on the other, by the thought of the provisions for his comfort and treatment behind the lines.

While we know that such great epidemics as have marked wars in the past are no longer possible, their rôle in history has not come to an end, but we can confidently hope that the day is not far when all of the known diseases will have disappeared from the earth.

The book is well written and, as far as we are able to judge, authentic. It is abundantly and excellently illustrated. While it does not reveal any historical facts which were unknown, it is none the less an excellent presentation.

MAZÛCK P. RAVENEL

Public Works Engineers' Year-book, 1938—Including the Proceedings of the 1937 Public Works Congress held at Atlanta, Ga., Oct. 4-6, 1937—Published by the American Public Works Association, 850 E. 58th Street, Chicago, Ill., 1938. 459 pp.

In addition to the more detailed discussion of selected problems of current interest to public works officials, this report contains a review and appraisal

of events and developments in all phases of public works engineering. Of interest to sanitary and public health engineers are the articles concerning water works practice, sewage treatment, and refuse collection and disposal.

In water works practice there was observed an increased use of pretreatment to reduce filter loads, the use of coarser sand sizes, more universal adoption of filter surface washing, the construction of all-steel tank filter plants, expedients for reducing condensation in filter plants, and various appurtenances designed to assist operators and promote better handling of plants. During the year two large cities built and operated water treatment plants for industrial water supplies.

More sewage treatment plants using the activated sludge process were built than were the settling tank-trickling filter type of plant. The Imhoff tank plant also appears to be supplanted by plain sedimentation tanks and separate sludge digestion. Improvements were noted in treatment plant mechanization, utilization of sewage sludge gas, and the training of treatment plant operators by state health boards.

Refuse collection and disposal was marked by improved collection vehicles with covered bodies and low loading heights. Incineration of garbage and rubbish is gradually supplanting inadequate dumping areas.

In conjunction with these subjects, descriptions are given of the Birmingham (Ala.) industrial water supply and the Atlanta (Ga.) sewage disposal system and refuse incinerator.

F. J. MAIER

Pneumonia and Serum Therapy—
By Frederick T. Lord, M.D., and Roderick Heffron, M.D. New York: Commonwealth Fund, 1938. 148 pp. Price, \$1.00.

This handbook appeared first in 1936

under the sponsorship of the Commonwealth Fund. This revised edition makes its appearance 2 years later, contains important new information concerning dosage and results of serum therapy for the various types of pneumonia, and discusses the use of the newly developed antipneumococcus rabbit serum. The authors, both of whom have been active in the Massachusetts Study of Pneumonia Control, are eminently qualified to write on the subject.

Especially interesting is the chapter on serum reactions and methods of prevention. The authors take the position, now rather generally accepted, that attempts to desensitize allergic patients is of uncertain value and should not be too heavily relied upon.

Lord and Heffron recommend that antipneumococcus serum be always given in divided doses. There is now a tendency in some clinics to give serum in one dose, but in the opinion of the reviewer, while this may be good practice in experienced hands, the recommendation for divided dosage is a safer procedure for the general practitioner.

The authors report 1,043 cases of Type I pneumonia treated with serum during the first 4 days of the disease with a death rate of only 13.9 per cent. It is interesting in this connection to note that Rogers has recently reported 1,023 cases of Type I pneumonia treated with serum within the first 4 days for which the fatality rate was identical—13.9 per cent.

This volume, containing as it does the last word on the serum therapy of pneumonia, should prove invaluable to both practitioners and public health officers.

RUSSELL L. CECIL

Introduction to Physiological Chemistry—
By Meyer Bodansky, M.D., Ph.D. (4th ed.). New York: John Wiley, 1938. 686 pp. Price, \$4.00.

With three highly successful editions to his credit, Dr. Bodansky's readers have come to expect from him a superior work, and he has not disappointed them in this latest edition.

Although an introduction to the subject, it is something more. Starting from the crossroads of chemistry, biology, and medicine, it penetrates a considerable way into one of science's enchanted lands. Thorough in its treatment of the subject matter, it is complete in all essentials. There is a judicious blending of the historical with the current. It includes all the new alignments and developments in this ever progressing science. It mentions the latest achievements in the isolation of virus proteins, the fundamental physical-chemical concepts in physiological oxidations, the objective tests of nutritional status, the newer approach to intermediary metabolism through substitutive insertion of deuterium, the heavy isotope of hydrogen into fats for purposes of identification. These are biochemical topics of the day. It is singularly free from errors, although one may be noted: "hemarolopia" is a misspelling for hemeralopia, and even this latter term is misapplied as a synonym of night blindness, nyctalopia being the preferred term.

To bring such a comprehensive body of material within the limits of 686 pages has involved careful and judicious selection. Even that would not be sufficient if it were not subjected to admirable condensation. Its style and arrangement help it to achieve brevity.

Not the least of the book's strong points is its full bibliography, particularly with references to monographs or reviews on many topics. This should continue to be helpful to students confronting the subject for the first time.

This new edition gives every indication that, as a textbook, it will continue to hold the esteem of students.

To those with a scientific leaning or training who have never gratified their suppressed urge to know how chemistry has helped to remake biology and medicine, or to those who may have lost and wish to renew their touch with developments in this field, this book has much in it that is keyed to their range.

H. D. KRUSE

"Marihuana"—The New Dangerous Drug—By Frederick T. Merrill. Washington: Opium Research Committee, Foreign Policy Association, 1200 National Press Building, 1938. 48 pp. Price, \$.15 (special rates for quantity orders).

The Foreign Policy Association has prepared a pamphlet on marihuana, which should be useful to health officers since it contains besides essential information, good illustrations of the plant in growth, its leaves, the seeds, and the dried flowering top which gives the largest yield of resin.

By the end of 1938 the majority of states had some prohibitory marihuana legislation. The Marihuana Tax Act of 1937, which is an internal revenue measure, nevertheless only helps to restrict the trade of marihuana to legitimate purposes.

This pamphlet will assist the health officer in the preparation of informative articles for the layman and enable him to cooperate intelligently with state and federal authorities in protecting his community against abuse of the use of this dangerous drug. J. ROSSLYN EARP

Physicians' Vitamin Reference Book—By the Medical Division, Professional Service Department, E. R. Squibb and Sons. New York: E. R. Squibb & Sons, 1938. 126 pp.

This book is an advertisement which is worth while and deserves notice. It has been well prepared by the Medical Division of the Professional Service Department of E. R. Squibb and Sons.

It is free from the ordinary blurb.

The description of each vitamin is preceded by a summary of estimated daily requirements, and stated in the International Units where these are available. The vitamin content of a number of foods is given. The Council on Pharmacy and Chemistry of the A.M.A. is frequently referred to. The entire book is well documented, and as far as we have been able to judge, is authoritative. We believe that as far as this part of the book goes it is entirely reliable and will be a useful guide to physicians, for whom it is written.

The book ends with a list of Squibb vitamin products, which is straight advertising. Many of these products violate the principles laid down by the Council on Pharmacy and Chemistry and the Council on Foods of the A.M.A., in that they smack of polypharmacy. Interestingly enough, a "New Series of Articles on Vitamins" has been prepared, the first of which appeared in the *J.A.M.A.*, February 19, 1938, p. 577. This says:

In a previous survey of progress in this field it was found necessary to warn the public and the medical profession against the commercial exploitation of individual vitamin preparations and particularly against the promotion of mixtures of vitamins as panaceas. The Council on Pharmacy and Chemistry is still convinced that for the present there seems to be no more logical basis for including a variety of vitamins in one preparation than there is for combining a number of other well known dietary essentials in a single pharmaceutical product.

The only exceptions to this are vitamins A and D, which occur together in nature.

No price is given for the book and we understand that it will be sent to any physician who writes to the firm for it. MAZÛCK P. RAVENEL

The Nursery Years—By Susan Isaacs. New York: Vanguard. Rep. 1936. 138 pp. Price, \$1.50.

The simplicity and frankness with which Susan Isaacs writes makes reading of *The Nursery Years* delightful. It is refreshing in that one does not have to wade through technical terminology, but in a few simply written, readable pages can get at some searching truths about child care and training.

The book was written originally for parents concerning their relationships with their children, but all adults can profit by the wisdom contained in its pages. Many after reading it should have dispelled from their minds some of the generally accepted notions about the care and training of children. For example Dr. Isaacs says that many parents who wish to be modern feel that they should leave the young child to himself most of the day, except for such routine times as eating, toileting, sleeping, and dressing and undressing. She feels, however, that if the baby is alone too much he may become bored and resort to finger-sucking and other similar behavior. Also that precious time may be lost—perhaps forever—which wisely used, could help in the building up of fine relationships between the child and its parents.

Striking statements reveal a philosophy which should instill self-confidence into parents and put them more at ease. "With time for their development, and the sense of our cheerful confidence, children will grow out of the behavior most of us worry about." And again, "It is a help to us in dealing with babes and young children merely to know that even those things they do which seem undesirable to us may be normal ways of growth."

But with all of this seeming casualness the author does not leave the adult feeling that he has no job of child-guidance, or that children will just grow out of their difficulties without help. She does simply and clearly get to the bottom of these difficulties, point out

possible reasons for various kinds of so-called "undesirable behavior" and ways of meeting it, "calmly and therefore more wisely." The book is highly recommended for its sound practicality.

ETHEL L. GORDON

Food Values of Portions Commonly Served—By Anna DePlanter Bowes and Charles F. Church. Philadelphia (3621 Woodland Ave.): E. P. Dolbey & Co., 1937. 12 pp. Price, \$.50.

This booklet consists of a table giving the protein, fat, carbohydrate, calcium, phosphorus, and iron content of foods, as expressed in grams per measures or portions frequently served. Values for vitamin A, B, C, D, and G are given in Sherman units, the energy values in calories, and the excess of acid or base values in cubic centimeters of normal solutions. The data, compiled and calculated from authoritative sources, have been conveniently arranged and classified for ready reference.

The table should prove useful to dietitians, nurses, and others in formulating special diets.

D. BREESE JONES

Allergy: Its Practical Application—By J. A. Rudolph, M.D. Philadelphia: Dorrance, 1937. 224 pp. Price, \$3.00.

This is a concise and well written book, embodying the extensive experience of the author as well as that of other well known workers in this new field.

We are glad to note the statement in the preface that allergy is as much a specialty as any of the other fields of medicine and that it is not limited to the making of a few skin tests which almost any physician can do with a fair amount of success. The author believes that this impression has been created largely by the detail

men of commercial drug firms. Certainly the interpretation of such tests and the practical application of measures indicated by them is a specialty and should be reserved for those who have given considerable study to the subject. While the author goes into treatment there is also much concerning prevention, especially by mechanical means, as the screening out of dusts, pollen, etc., and there is a chapter on The Immunology of Allergy well worth reading.

The book ends with an extensive bibliography in which, however, there are a number of mistakes. It is also rather confusing to find on the first page references starting with 142. The book can be recommended for those for whom it is designed. The printing and make-up are good.

MAZŮCK P. RAVENEL

Sanitary Engineering as a Career: A Monograph (from "Careers")—The Institute for Research Devoted to Vocational Guidance, 537 South Dearborn Street, Chicago, Ill., 1938. 20 pp. Price, \$1.00.

The profession of sanitary engineering evolved with the discovery that certain microscopic organisms and bacteria are the causes of some of the worst human diseases. In attempting to minimize the harmful effects of such organisms, the sanitary engineer has been primarily engaged in designing and building structures to promote cleaner and more healthful environments. However, "it has not been so many years ago when people generally thought of the field of sanitary engineering as one limited to questions of water supplies, stream pollution, trade wastes, and the collection and disposal of garbage and sewage.

"Engineering methods have proved so successful that now they are being applied in many other lines of sanitation, and at present the sanitary engineer is

called upon to deal also with pasteurization of milk; protection of oyster-growing areas; problems of housing, such as overcrowding, light, heat, and ventilation; malaria control; plague eradication; destruction of vermin; industrial sanitation; smoke abatement; noise reduction; protection of swimming pools and bathing beaches; special hazards of comparatively recent importance, such as poisonings by refrigerants, chemicals used in fumigation, and by hair dyes, shoe dyes, moth-proofing compounds, and like products; and the abatement of nuisances of many kinds."

In performing this work, the engineer may be employed by a government service, manufacturer of sanitary engineering equipment, a consulting engineer, or an industry having problems in disposing of their waste products.

While the responsibilities of the profession are generally large the monetary returns are small. The sanitary engineer derives satisfaction from the wide variety of interest his profession presents, the opportunity for associating with successful men of other professions, and the realization that he is engaged in doing decidedly worth while things.

ARTHUR P. MILLER

The Biology of Arteriosclerosis—
By M. C. Winternitz, M.D., R. M. Thomas, M.D., and P. M. LeCompte, M.D. Springfield, Ill.: Thomas, 1938. 142 pp. Price, \$4.00.

The work recorded in this volume will unquestionably serve as the opening wedge into the wilderness of unknowns that have masked the pathogenesis of arteriosclerosis through the

ages. There, of course, are limitations to the application of the principles developed, but one can with little imagination see their application to studies in a number of diseases affecting the vascular system.

The authors are to be commended for their foresight and for carrying through a personally developed idea in such a clear-cut manner. The volume is unusually readable, in good diction, well prepared and organized, and in such language that anyone of general scientific training can understand. The photomicrographs and drawings, many of which are in remarkable color reproductions, illustrate the work to a very unusual degree. The methods of clearing the specimens for purposes of interpretation and illustration add great value.

M. PINSON NEAL

Eat and Keep Fit—*By Jacob Buckstein, M.D. New York: Emerson Books, 1938. 128 pp. Price, \$1.00.*

The author presents in popular style the science of nutrition and its relation to health and general well being. The various food elements are discussed in a logical and interesting manner. The chapter on false notions about food combinations and food fads and their fallacies is very well presented and should prove instructive to the layman. Exception may be taken to a number of apparently loose statements, which need further explanation. The book ends with a timely chapter on sane diets to lose or to gain weight. This book should prove of value in educating the person not versed in nutrition as to the importance of diet and its influence on good health.

C. R. FELLERS

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Preventing Pneumonia—Being the very last word in the diagnosis, prevention, and care of pneumonia, this valuable committee report should be studied by all. What some states and cities have already done toward meeting their responsibilities is recorded and what remains to be done is convincingly stated.

AXON. Pneumonia Mortality and Measures for Prevention. Pub. Health Rep. Supp. 142 (July), 1938.

Deaths Down, Births Up—For the registration area, the death rate was lower, the infant mortality rate lowest in history, while the birth rate was higher than either of the past 2 years. The provisional figures for 1937 are: 11.2; 54.4; 17.0 respectively. Gratifying as the infant death rate is, there are indications that it can be improved, for some large cities have rates almost half the national average.

AXON. Provisional Birth, Death, and Infant Mortality Rates for 1937. Pub. Health Rep. 53, 26:1072 (July), 1938.

Further Light on Scandinavian Venereal Disease Prevention—Investigating venereal disease control programs in Scandinavian countries, this British Commission discovered that the compulsory features do not meet serious opposition, and that extreme measures are seldom necessary. Why venereal disease control works well in these countries is explained, but the point is made that the same situations do not exist in England. Though syphilis has been markedly reduced, gonorrhea has not.

AXON. Anti-Venereal Measures in Scandinavia. Brit. M. J. June 11, 1938, p. 1277.

Preventing Neonatal Deaths—Neonatal deaths have not declined as have infant deaths. This Chicago study indicates that improvement in obstetric care, the avoidance of certain drugs, measures to prolong pregnancy, and proper resuscitation would make the statistics better.

BUNDESEN, H. N., *et al.* Factors in Neonatal Deaths. J.A.M.A. 111, 2:134 (July 9), 1938.

Where More than Medicine Is Needed—Who will question these findings? Tuberculosis precipitates economic family problems. Infection cannot be controlled in families with incomes below subsistence level. Some medical services are wasted because social needs are not met. Tuberculosis prevention programs generally have not accepted economic responsibilities. Some relief is now available, but extension of services is needed in most communities.

BURRITT, B. B. Social and Economic Problems in the Control of Tuberculosis. Milbank Quart. 16, 3:287 (July), 1938.

The Grim Reaper's Tuberculosis Harvest—Some gloomy findings about deaths among tuberculosis cases which health educators would do well to keep in the back of the mind when optimistically telling the world that early discovery means early recovery. More than a fifth of the minimal cases were dead after 5 years, and nearly half those moderately advanced had died.

DOWNES, J. A Study of Mortality among Individuals with Active Tuberculosis. Milbank Quart. 16, 3:304 (July), 1938.

Questioning Some Influenza

Theories—Though most recent influenza epidemics have been due to the same virus, some, however, have been shown to be caused by a different one. Immunity to influenza does result from infection, but the degree of immunity varies. Many epidemiologic problems are recognized but cannot be answered in the present state of our knowledge.

FRANCIS, T., JR. The Immunology of Epidemic Influenza. *Am. J. Hyg.* 28, 1:63 (July), 1938.

British Health Services—American sanitarians and medical leaders who are inclined to work up a lather over preventive and curative medical relationships would do well to read the unimpassioned discussion of the needs in British public health which visualizes greatly extended health services, a closer relationship between hospitals, and health insurance, the latter service to include dependents.

FRAZER, W. M. State Medicine and Industrial Hygiene. *J. Roy. San. Inst.* 1, 10:587 (July), 1938.

Levaditi Did It First—If you are curious to know who invented the hen egg as a culture medium and to what bacteriologic, biologic, and immunologic uses the poor chick embryo has been put during recent years, you will find this paper a goldmine of information.

GOODPASTURE, E. W. Some Uses of the Chick Embryo for the Study of Infection and Immunity. *Am. J. Hyg.* 28, 1:111 (July), 1938.

Heat, Humidity, and Health—Excessive death rates from heat exhaustion and conditions in which it is a secondary cause bounce up with the first major heat wave. Excess mortality is slight with succeeding hot spells. The Central states are most frequently affected, but sometimes the North Atlantic states cities suffer the same experience.

GOVER, M. Mortality During Periods of Excessive Temperature. *Pub. Health Rep.* 53, 27:1122 (July 8), 1938.

Protecting Uncooked Pork Ad-dicts—Pasture raised swine are generally free from trichinae; garbage fed swine have a high incidence of infection. Human trichinosis depends upon food habits of individuals plus the amount of infection in swine. Should we require the cooking of meat in the garbage that is fed to swine?

HALL, M. C. Studies on Trichinosis. *Pub. Health Rep.* 53, 26:1086 (July 1), 1938.

Children's Permanent Teeth—Out of that rich mine of hygienic information, Hagerstown, come some unhappy findings about elementary school children's teeth. It appears that carious defects appear in permanent teeth 6 times as fast as they are cared for; and that to do a proper job in this one field alone, it would take a tenth of the time of all the dentists available.

KLEIN, H., and PALMER, C. E. The Dental Problem of Elementary School Children. *Milbank Quart.* 16, 3:267 (July), 1938.

Doubts about T.B. Programs—Because many are infected but only a few contract tuberculosis, a host of questions are raised. So many in fact, that the author doubts whether the antituberculosis measures now employed may certainly be assumed to be sufficient to solve the problem. A usefully disturbing paper.

MILLER, J. A. Some Unsolved Problems of Tuberculosis. *J.A.M.A.* 111, 2:111 (July 9), 1938.

Effective Leadership at Work—We pay for disease whether we cure it or not. We have far to go before we shall have taken up the lag for preventive medicine between what we know and what we do. These two striking statements of frequently suggested ideas are culled from this general presentation of the U.S.P.H.S. Program.

PARRAN, T. The Work and Aims of the United States Public Health Service. *New Eng. J. Med.* 219, 3:75 (July 21), 1938.

Critical Appraisal of Tuberculosis Prevention—Ways must be found to help the families of tuberculous patients. Unless financial problems can be solved, the total benefit of existing treatment facilities cannot be secured, and it becomes futile to create more institutions for care of cases, badly needed though they be. Better case finding and case holding programs are also indicated.

PLUNKETT, R. E. Tuberculosis Control. *Am. Rev. Tuberc.* 37, 6:612 (June), 1938.

Soup for Babies—Canned vegetable soup added to infants' diet at the first visit to the clinic did not produce any digestive upsets, but it did not significantly influence growth.

POOLE, M. W., *et al.* Addition of Vege-

table Soup and Strained Vegetables to Diet of Artificially Fed Infants. *Am. J. Dis. Child.* 55, 6:1158 (June), 1938.

Decentralized Health Administration—New York City health centers, each serving a population greater than most large cities, give promise of solving the otherwise insoluble health administrative problems of the world's greatest accumulation of human beings. Although the building program which will comprise thirty districts is not complete, the 4 year experience of the first units has demonstrated the practicability of the scheme.

RICE, J. L., and BARNARD, M. W. Four Years District Health Administration in New York City. *Milbank Quart.* 16, 3:253 (July), 1938.

ASSOCIATION NEWS

THE KANSAS CITY MEETING

THIS is the last but one issue of the *Journal* to bring to the membership news and notes of the Kansas City Annual Meeting.

Railroad rates, hotel information, Local Committee plans for entertainment and inspection trips, the preliminary program of the scientific sessions have all been published. Last month's *Journal* conveyed a considerable portion of this information and should be consulted. It will answer the most frequently asked questions. A news letter to the membership is in preparation and will be mailed immediately after Labor Day. An attempt will be made therein to catch all loose ends together and refer readers by page and number to details previously published and to summarize what is in store for us at Kansas City. The Chairman of the Local Committee for the 67th Annual Meeting, Dr. Edwin Henry Schorer, will tender by mail on or about October 1 his assurances to all that a hearty welcome awaits them in his city.

While the dates for the meeting have been widely publicized as October 25-28, Tuesday to Friday, inclusive, it must be pointed out that much of interest awaits the early arrival in Kansas City, whether or not he or she is a member of the several organizations which will meet on Monday, October 24. The Conference of State Sanitary Engineers and the Conference of State Laboratory Directors will hold meetings limited to their constituents. The American School Health Associa-

tion, on the other hand, will exclude no one from the interesting session planned for Monday afternoon. The International Society of Medical Officers will sponsor an Institute on the Practical Administration Affairs of the Health Officer on Monday. All health officers and public health workers interested in administrative problems are cordially invited to attend. There will be meetings both morning and afternoon. The program in full will be published in the October *Journal*. The latch string is out for all to attend the dinner meeting Monday evening sponsored by the Association of Women in Public Health. And the local public health workers organized in the Missouri Public Health Association ask us to extend an invitation to everyone to drink a cup of tea with them between 5 and 7 on Monday and meet many of the members of the Local Committee.

A considerable number of delegates from the East, whether they arrive on Monday, Tuesday, or earlier, are anticipating their first ride on the Santa Fe's streamlined trains between Chicago and Kansas City. This rapid service is only 5 months old and deserves a trial. The Santa Fe's advertisement, on page XVI tells all about it.

Those who will drive to Kansas City are probably well provided with road maps and directions. If any doubts arise as to best roads and routes, the Convention and Visitors Bureau in Kansas City or Dr. Schorer's office will be glad to lend a helping hand.

Although the Program Committee, the Local Committee, and the Association office have tried to anticipate all inquiries and provide information before it is asked for, it is safe to say that items of interest will present themselves as the meeting approaches, and readers are urged to consult this section of the October *Journal* for last minute announcements.

In making application for hotel accommodations, it is necessary that four choices of hotels be indicated and that a reasonable range of rates desired be shown. Whenever possible, arrangements should be made for occupancy of double rooms; only a limited number of single rooms are available.

HOUSING COMMITTEE
1028 Baltimore Avenue
Kansas City, Missouri

Date.....

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

William H. Ball, M.D., Apalachicola, Fla.,
Director, Franklin and Gulf County Health
Unit
Thomas H. Biggs, M.D., Thurston County
Court House, Olympia, Wash., Health
Officer, Thurston-Mason-Olympia District
Edward R. Harris, M.D., Township Hall,
Kirkland Lake, Ont., Canada, Medical
Officer of Health, Township of Teck
Samuel Hyman, M.D., C.P.H., 18 Pearl St.,
Utica, N. Y., Assistant District State Health
Officer
Edwin H. Jorris, M.D., 200 Pearl St., Sparta,
Wis., District State Health Officer
R. W. Kite, M.D., Court House, Bellingham,
Wash., Whatcom County Health Officer
Richard A. Koch, M.D., Whitman County
Health Dept., Colfax, Wash., Health
Officer
Fred K. Laurentz, M.D., Bell County Health
Unit, Temple, Tex., Assistant Director
Norman E. Magnussen, M.D., Pierce County
Health Dept., Tacoma, Wash., Health
Commissioner
Joseph A. Markley, M.D., Main St., Weston,
W. Va., Lewis District Health Officer
Frank M. McHugh, M.D., 17 Exchange
Place, Salt Lake City, Utah, Member,
Board of Health
A. Erin Merkel, M.D., Court House, Med-
ford, Ore., Jackson County Health Officer
Frank R. Mount, M.D., Medical Arts Bldg.,
Portland, Ore., Member, State Board of
Health
Edward E. H. Munro, M.D., Grand Junc-
tion, Colo., City Physician.
Henry Raile, M.D., 19 S. Wolcott St., Salt
Lake City, Utah, Assistant City Health
Commissioner
Guy V. Rice, M.D., Jesup, Ga., Wayne
County Commissioner of Health
David R. Rich, M.D., Union County Health
Unit, LaGrande, Ore., Union County
Health Officer
Peter H. Rozendal, M.D., Klamath County
Health Dept., Klamath Falls, Ore., Health
Officer
Robert H. Trimble, M.D., Court House,
London, O., Health Commissioner
T. Oscar Vinson, M.D., Griffin, Ga., Health
Officer, Griffin and Spalding County

Laboratory Section

Avery Caine, 228 Douglas St., Salt Lake
City, Utah, Laboratory Technician, Idaho
Falls Latter Day Saints' Hospital (on
leave)
Robert T. Foster, 207 W. Market St., War-
rensburg, Mo., State Bacteriologist
Thomas L. Hartman, 804 Neches St., Austin,
Tex., Bacteriologist, State Dept. of Health
Vladimir G. Isvekov, M.D., 1403 Elgin Ave.,
Houston, Tex., Director, Medicolegal Labo-
ratory
Bernadine S. Langlie, 2300 Franklin Ave.,
Seattle, Wash., Bacteriologist-Serologist,
State Dept. of Health

Physician, graduate of Johns Hopkins Medical School and well qualified in medicine and tuberculosis, will consider a clinical position in the medical field. M377

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

Experienced teacher in bacteriology and public health; Ph.D., Cornell; now professor in Grade A medical school, will consider teaching, executive or administrative position. M327

NEWS FROM THE FIELD

MENTAL HYGIENE SYMPOSIUM

THE National Committee for Mental Hygiene has announced a symposium on mental health, to be presented before the Section on Medical Sciences of the American Association for the Advancement of Science at the Richmond, Va., session, December 28-30, 1938. Collaborating in the enterprise are the American Psychiatric Association, an affiliated body of the A.A.A.S.; the U. S. Public Health Service; the Mental Hospital Survey Committee, composed of 8 national medical bodies; the National Committee for Mental Hygiene; and a special committee of psychiatrists who are developing the program for the symposium under the chairmanship of Dr. Walter L. Treadway, Assistant Surgeon General of the Public Health Service in charge of mental hygiene activities.

The symposium will provide an unusual opportunity to bring the problems of mental health before the forum of the A.A.A.S. and, through it, to the scientific and lay public of America. Its object will be, essentially, to bring about a synthesis of our present knowledge of the problem, to evaluate past experience, to crystallize aims and objectives, and to marshal the scientific forces of the nation for a concerted and coördinated attack on mental disorders and disease. It will be the first time in the history of American psychiatry and the mental hygiene movement that the subject has received the special attention of this scientific body as a major topic on its agenda.

NEW HAVEN HOUSING AUTHORITY

THE appointment has been announced of the New Haven [Conn.] Housing Authority, of which Professor C.-E. A. Winslow, of Yale University,

New Haven, is Chairman, and Elizabeth Fox, Executive Director of the New Haven Visiting Nurse Association, and Associate Professor of Nursing Education at Yale University, is a member. Other members include: James W. Hook, an industrialist, who is also Chairman of the New England Council; George W. Crawford, lawyer; and James F. Welch, Business Agent of the Bricklayers' Union.

In addition to the chairmanship of this Authority, Professor Winslow is Chairman of the Committee on the Hygiene of Housing, American Public Health Association, and a representative of the United States in the Housing Section of the Health Committee, League of Nations. He is identified also with the National Association of Housing Officials Committee on Physical Standards and Construction, and is Chairman of the American Society of Heating and Ventilating Engineers Committee on Research.

PASADENA MALNUTRITION STUDY

A JOINT project of the Pasadena, Calif., City Health Department and the Council of Social Agencies in Pasadena is a survey launched recently to determine if citizens are securing a diet adequate to prevent malnutrition.

A preliminary study of 80 families will be made immediately in coöperation with the California Institute of Technology.

BROOKLYN MATERNITY CARE

A PLAN under the auspices of the Kings County Medical Society, Brooklyn, N. Y., provides that every expectant mother in Brooklyn will receive full medical attention regardless of her ability to pay. Mem-

bers of obstetric staffs in the 49 public and private hospitals of Brooklyn will grant consultation. Except in instances where the attending physician provides evidence that the patient can afford to pay for all or part of his services, compensation will not be required.

This new program was adopted following a survey by the Committee on Maternal Welfare of the Kings County Medical Society.

NEW HAMPSHIRE OCCUPATIONAL DISEASES STUDY

A PRELIMINARY study of industries in New Hampshire, with reference to occupational disease, is being made by the New Hampshire State Board of Health. The purpose of the study is to obtain information concerning the environment associated with the various occupations which potentially may have an effect on the health of employees.

This industrial survey is a result of recommendations made in the report of the Commission for the Study of Occupational Diseases in New Hampshire to the Governor in 1937.

BIRTH REGISTRATION PAMPHLET

A FOUR-PAGE pamphlet entitled "What Happens When Birth Registration Goes Amiss?" was recently distributed to all physicians, midwives, and public health nurses by the Maryland State Department of Health.

Birth registration goes amiss because of failure to file birth certificate, giving wrong date, wrong sex, wrong name, or because of illegible writing.

SHELLFISH AREA CONDEMNED

THE sale for human food of shellfish taken from the "Great Bay Area" of New Hampshire has been banned by the State Board of Health. Analyses of clams and water from the lower part of the area have definitely shown that

shellfish taken there are unfit for food because of the contamination of rivers flowing into the area with sewage from Portsmouth, Dover, and other towns.

Studies are also in progress of clams from the mouth of the Exeter River and oysters from the Oyster River.

PASTEURIZED MILK IN ALASKA

GRADE "A" pasteurized milk is now available in the local markets of Alaska. The dairies have been graded in accordance with the U. S. Public Health Service Standard Milk Ordinance.

The only pasteurizing plant operating in the territory of Alaska has been awarded Grade "A" and an average of 400 gallons of pastuerized milk is daily being produced by this plant.

INDIANA'S INDUSTRIAL SURVEY

THE new department of the State of Indiana, the Bureau of Industrial Hygiene, is conducting a study of industrial hazards.

This survey is expected to provide a cross-section of health conditions in the factories of Indiana by checking those industries known to have hazardous health conditions.

COMMUNICABLE DISEASE CONTROL IN MICHIGAN

THE appointment of an advisory committee to assist in determining plans and policies for more effective control of communicable diseases has been announced by Don W. Gudakunst, M.D., Health Commissioner of Michigan, with the approval of the State Council of Health.

The new committee, serving in an advisory capacity to Filip C. Forsbeck, M.D., Director of the Bureau of Communicable Diseases, will include: C. D. Barrett, M.D., E. E. Martmer, M.D., Allan J. McLaughlin, M.D., C. A. Neafie, M.D., Franklin H. Top, M.D., and V. K. Volk, M.D.

ONTARIO PASTEURIZATION LAW

ONTARIO is the first Canadian province to adopt a compulsory pasteurization law.

Beginning October 1, the milk supply of all Ontario cities, towns and adjoining suburban areas will be pasteurized, and by December 31, the order will apply to the whole province.

PENNSYLVANIA CANCER CLINICS

SEVEN cancer clinics will be established by the Pennsylvania State Health Department. This plan was discussed at a recent conference of the department and a program of study and experimentation was launched as the basis for drafting legislation.

NEW YORK STATE HEALTH OFFICERS ASSOCIATION

AT the annual conference of Health Officers and Public Health Nurses, held June 28-30 under the auspices of the New York State Department of Health, in Saratoga Springs, N. Y., new officers were elected as follows by the New York State Health Officers Association:

President—Charles G. Lenhart, M.D., Spencerport

First Vice-President—Myron M. Metz, M.D., Williamsville

Second Vice-President—John H. Flynn, M.D., Troy

Third Vice-President—William H. Runcie, M.D., Freeport

Secretary—Marian Wilcox, M.D., Tonawanda

Treasurer—George S. Price, M.D., Fairport

MICHIGAN DOCTORS BECOME MAYORS

THE following physicians in Michigan have been elected Mayors of the places indicated:

Dr. Thomas E. DeGurse—Marine City

Dr. Frank V. Carney—St. Clair

Dr. Arnold R. Miller—Harrisville

Dr. Alden G. Sheets—Eaton Rapids

Dr. Buell H. Van Leuven—Potoskey

PERSONALS

Central States

DR. GEORGE H. BISCHOFF, of Akron, Ohio, has been appointed to take charge of the Maternal and Child Health Program of the Idaho State Department of Health, with headquarters at Boise.

FRANCIS HARRINGTON, M.D.,[†] Health Commissioner of Minneapolis, Minn., and founder and Director of the Lymanhurst Health Center, was honored at a dinner given recently at the Minnesota Union, University of Minnesota. This occasion also commemorated the 17th anniversary of the health center as a school for tuberculous children.

WILL H. MOORE, M.D.,[†] of Valley City, N. D., was elected President of the North Dakota Health Officers' Association, at the annual meeting recently held in Bismarck. MAYSEL M. WILLIAMS, M.D.,[†] of Bismarck, was elected Secretary.

DR. ALFRED G. RICE, of Northville, Mich., has been appointed Director of Tuberculosis Control in North Alabama, succeeding DR. KELLIE N. JOSEPH, of Birmingham, who retired to reënter private practice.

DR. CONRAD S. SOMMER, Medical Director, Illinois Society for Mental Hygiene, has been appointed Director of the Society, succeeding HELEN L. MYRICK, resigned.

WILMIER M. TALBERT, M.D.,[†] of Decatur, Ill., formerly City Physician for Decatur, has been appointed Health Officer of a new district health unit with headquarters at Clinton. The new unit includes Macon, Moultrie, Dewitt, Piatt, and McLean Counties.

MAYO TOLMAN has been appointed Director of the Division of Vital

* Fellow A.P.H.A.

† Member A.P.H.A.

Statistics in the Iowa State Department of Health, Des Moines.

Eastern States

DR. ALICE HAMILTON,* of Boston, Mass., received the honorary degree of Doctor of Science from the University of Rochester, N. Y., at its 88th annual commencement, June 20.

NINA B. LAMKIN,† formerly Health Education Consultant with the Bellevue-Yorkville Health Demonstration, New York, N. Y., has recently been appointed School Health Consultant in the Division of Maternal and Child Health, State Department of Public Health, Santa Fe, N. M.

D. Y. MOORE, M.D.,* Chairman of the Board of Health and Health Officer of Manchester, Conn., for nearly 25 years, has been appointed Medical Examiner, to succeed the late Dr. LE VERNE HOLMES.

THOMAS M. RIVERS, M.D.,† Director of the Hospital of the Rockefeller Institute for Medical Research, New York, N. Y., received the honorary degree of Doctor of Science from the University of Rochester, N. Y., at its 88th annual commencement, June 20.

RICHARD EDWIN SHOPE, M.D., of the Department of Animal and Plant Pathology, Rockefeller Institute for Medical Research, Princeton, N. J., has been awarded the Alvarenga Prize for 1938 by the College of Physicians of Philadelphia. Dr. Shope received this award in recognition of his research in influenza. The Alvarenga Prize was established by the will of Pedro Francisco deCosta Alvarenga to be awarded July 14 of each year to the author of the best memorial or unpublished essay on any branch of medicine deemed worthy of the prize.

ALLAN A. TWITCHELL,† Technical Secretary of the Committee on the Hygiene of Housing, of the American

Public Health Association, appeared before the Housing Round Table of the National Planning Conference in Minneapolis, Minn., recently, where he discussed the hygienic aspects of housing.

Southern States

DR. JOHN S. ANDERSON, of New Bern, N. C., Health Officer of Craven County, has resigned to become Health Officer of Cabarrus County, succeeding DR. DANIEL G. CALDWELL, of Concord, resigned because of ill health.

EDWARD S. ARMSTRONG, M.D., of Augusta, Ga., has been appointed Health Commissioner of Crisp County.

DR. HENRY H. ASHER, of Ozark, Mo., has been appointed head of District No. 6—a recently formed health unit, consisting of Barton, Jasper, Newton, McDonald, Dade, Lawrence, Barry, Stone, Christian, Taney, Ozark, Douglas, Webster, and Wright Counties.

WILL H. AUFRANC, M.D.,† of Kennett, Mo., is in charge of District No. 3, a recently formed health unit including Pemiscot and Dunklin Counties.

HELEN BEAN, Public Health Nursing Consultant, U. S. Public Health Service, Washington, D. C., has been appointed director of a new bureau of public health nursing in the Michigan State Department of Health, Lansing, effective early in September.

RAY H. BIGGS, M.D.,† of New Albany, Miss., has been appointed Health Officer of Madison County, succeeding CECIL C. SMITH, M.D., C.P.H.†

ENOCH M. BRYAN, M.D.,† of Fredericktown, Mo., has been appointed

* Fellow A.P.H.A.

† Member A.P.H.A.

to take charge of District No. 4, a recently formed health unit consisting of Butler, Wayne, Bollinger, Cape Girardeau, Perry, St. Genevieve, Madison, Iron, and Washington Counties.

WILLIAM B. BUCKNER, M.D., of Moss Point, Miss., has been elected Health Commissioner of Dougherty County, Ga., with headquarters in Albany.

JAMES A. CRABTREE, M.D.,* of Chattanooga, Tenn., has been appointed to take charge of the survey of cancer of the lungs which the U. S. Public Health Service is conducting in Washington, D. C., Hospitals, as part of a national study.

RUTH E. FAIRBANK, M.D.,† Associate in Psychiatry, Johns Hopkins University School of Medicine, Baltimore, Md., has been appointed Professor of Hygiene at Mount Holyoke College, South Hadley, Mass.

CHARLES W. MEINERSHAGEN, M.D.,† of Salem, Mo., has been appointed to take charge of District No. 5, a recently formed health unit consisting of Howell, Oregon, Ripley, Carter, Reynolds, Shannon, Texas, Dent, Pulaski, Phelps, and Crawford Counties.

ROY W. MCGEE, M.D., of Ben Hill, Ga., will study for one year at the School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md., before taking over the position of Director of Health of Fulton County.

J. W. ROY NORTON, M.D.,† Assistant Director of County Health Work on the staff of the North Carolina State Health Department, Raleigh, N. C., has been appointed Assistant Director of the Division of Preventive Medicine.

LONSDALE J. ROPER, M.D.,* recently Associate Director of the venereal disease program of the Virginia State Health Department, Richmond, has

been made Director of Rural Health for the Department, succeeding CHARLES HOWE ELLER, M.D., Dr.P.H.*

SHIRLEY C. TITUS, R.N.,† Director of the Vanderbilt University School of Nursing, Nashville, Tenn., has resigned from that position.

DR. THEODORE L. WADDLE, of Dexter, Mo., has been appointed to take charge of District No. 2, a recently formed health unit consisting of Stoddard, Scott, New Madrid, and Mississippi Counties.

ROBERT D. WRIGHT, M.D.,† of Osceola, Mo., has been appointed to take charge of District No. 7, a recently formed health unit consisting of Bates, Vernon, Henry, St. Clair, Cedar, Benton, Hickory, Polk, Morgan, Camden, Dallas, and Laclede Counties.

FRANCES HELEN ZEIGLER, R.N., has been appointed Director of the Vanderbilt University School of Nursing, Nashville, Tenn., succeeding SHIRLEY C. TITUS, R.N.,† resigned. Miss Zeigler has served as Dean of the Nursing Division of the Medical College of Virginia since 1929.

Western States

JOHN O. RAFFETY, M.D.,† of Oakland, Calif., has been appointed Health Officer of Yale County, at Woodland, Calif.

Foreign

DR. JAMES FENTON,* of London, a member of Executive Council of the Royal Institute of Public Health and Hygiene, was recently created a Commander of the British Empire (C.B.E.). Dr. Fenton is an Honorary Member of the American Public Health Association.

* Fellow A.P.H.A.

† Member A.P.H.A.

CONFERENCES AND DATES

- American Association of Railway Surgeons—23rd Annual Meeting. Palmer House, Chicago, Ill. September 19–23.
- American Association of School Health. Kansas City, Mo. October 24–28.
- American Association of State Registration Executives. Kansas City, Mo. October 25–28.
- American Congress of Physical Therapy—17th annual scientific and clinical session. (Preceded by instruction seminar in physical therapy for physicians and technicians, September 7–10.) Palmer House, Chicago, Ill. September 12–15.
- American Dental Association. Hotel Statler, St. Louis, Mo. October 24–28.
- American Dietetic Association—21st Annual Meeting. Hotel Schroeder, Milwaukee, Wis. October 9–14.
- American Hospital Association. Dallas, Tex. September 26–30.
- American Occupational Therapy Association—22nd annual. (Preceded by instruction seminar in physical therapy for physicians and technicians, September 7–10.) Palmer House, Chicago, Ill. September 12–15.
- American Public Health Association—67th Annual Meeting. Hotels Muehlebach, President, Kansas Citian, Kansas City, Mo. October 25–28.
- American Public Works Association. New York, N. Y. October 3–5.

Sylvatic Plague*

K. F. MEYER, PH.D., M.D., F.A.P.H.A.

Professor of Bacteriology, Director of the George Williams Hooper Foundation, and Director of Curricula in Public Health, University of California, San Francisco, Calif.

THE Committee on Sylvatic Plague has collected, in coöperation with the state health officers and Dr. C. R. Eskey, U. S. Public Health Service, statistical data concerning the extent of human and rodent plague as well as *Pasteurella pestis* infection of fleas and other insects on the American Continent. The pertinent observations may be summarized as follows:

EPIDEMIOLOGICAL OBSERVATIONS DURING 1937

I. HUMAN PLAGUE

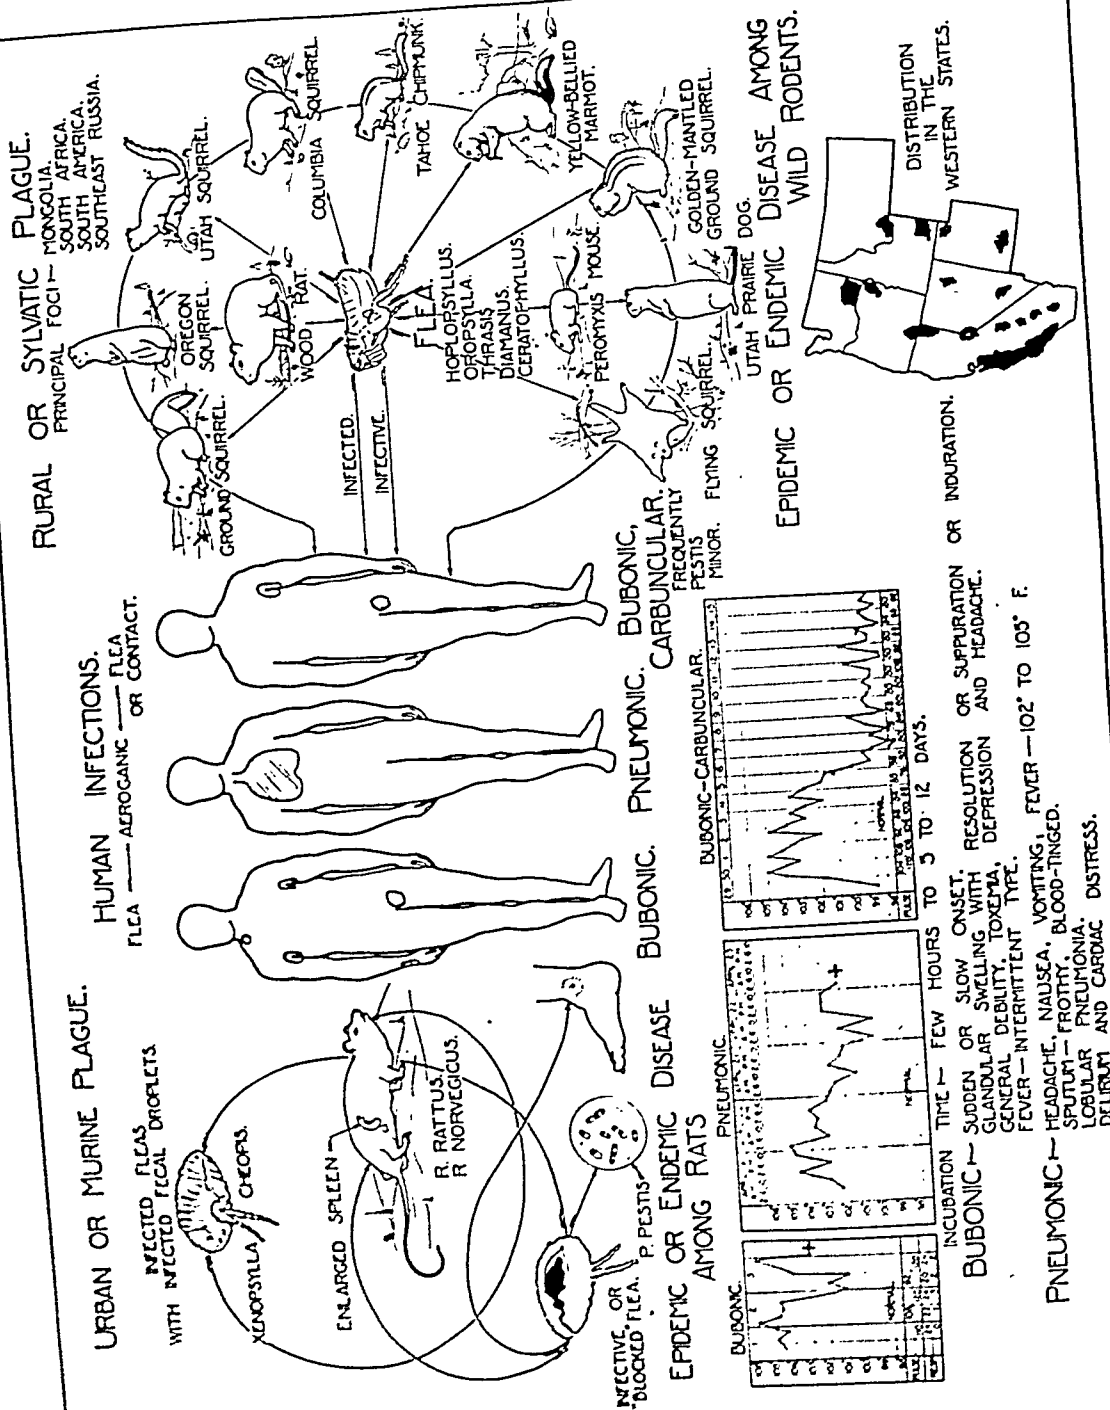

Two human cases of plague have been bacteriologically proved, one in Nevada and one in California. One terminated fatally. The histories contain observations of considerable interest:

Nevada Case—A university professor, age 64, while returning from a one day outing on May 28, 1937, from his summer home at

Zephyr Cove, Lake Tahoe, felt tired. On May 29 he had a severe chill followed by nausea and vomiting and later high fever. He became rapidly worse, began to have general aching pains throughout, more marked in the lower extremities and left groin. He was hospitalized on May 30 with a left inguinal bubo and a rectal temperature of 104.6°. On the middle third of the inner surface of the left tibia a small red area resembling a fleabite was present. This lesion changed into a necrotic scab and ulcer which healed very slowly. The puncture fluid of the edematous tender lymph node secured on May 31 yielded bacterioscopically and by culture *P. pestis*. The blood culture remained sterile. Intramuscular administration of 100 c.c. dry anti-plague serum of the Pasteur Institute and blood transfusions lowered the temperature. The patient developed a cough, but repeated examinations of the sputum failed to show plague bacilli. A transitory toxic nephritis retarded the recovery, and the patient was discharged on the 26th day of his illness.

Although infected rodents were not found in the vicinity of the summer home, fleas carrying plague bacilli were discovered in the region. The plague ulcer, which led to the development of the left inguinal bubo, resulted from a fleabite contracted on May 24 when the

* Third Report of the chairman of the Sylvatic Plague Committee of the Western Branch American Public Health Association, read before the Ninth Annual Meeting in Portland, Ore., June 6-8, 1938.

patient had worked in and around his summer home. The anti-plague serum was unquestionably responsible for the prevention of a septicemic state and the uneventful recovery.

California Case—A 7 year old girl with a history of having been bitten by a chipmunk on August 10, 1937, while on vacation at Huntington Lake, Fresno County, complained on August 14 of pain in the left arm and shoulder, vomited, had high fever, and an unusually rapid pulse. She was hospitalized on August 16, temperature of 104° F., W.B.C. 26,600, and an indurated mass in the left axilla. Sulphanilamide was given internally and local compresses were applied. A surgical exploration of the axilla on August 17 revealed an edematous infiltration and a few enlarged lymph nodes. On the 18th the patient was toxic and irrational, showed a petechial rash on the extremities, and despite a blood transfusion expired early in the afternoon. An antemortem blood culture yielded Alpha streptococci and *P. pestis*.

According to reports made by the Forest Ranger stationed at the Lake, an epidemic disease had appeared among the rodents of the area and had greatly reduced the population during the month of August. The examination of 434 rodents (218 *Citellus beecheyi*, 106 Golden mantled squirrels, 86 chipmunks, flying squirrels, rats and mice) revealed 3 ground squirrels with anatomical and bacteriologically proven lesions of plague. In addition, by *mass inoculation of organ suspensions* (8 pools) *into guinea pigs*, latent plague was demonstrated in chipmunks, Golden mantled and flying squirrels as well as mice. Infected fleas were detected through the customary injection of triturated suspensions of the insects. In 48 pools tested, 6 were found to contain fleas carrying *P. pestis*.

These two observations on human plague emphasize again the following important facts:

1. Since plague infections may be encountered anywhere in the Sierra Nevada regions, it is imperative that

the differential diagnosis be carefully weighed and surgical procedures deferred until the nature of the infective process has been established. Lymph node punctures are most useful in making an early diagnosis.

2. The early use of anti-plague serum, which is available at the Hooper Foundation and the U. S. Public Health Service laboratories in San Francisco and Hamilton, Mont., is definitely indicated.

3. The owners or guests of summer homes visiting infected areas should be instructed to rat and rodent proof their buildings and, if practical, institute measures which will reduce or eliminate the flea population in their immediate surroundings.

4. With unremitting insistence, the public, in particular children, should be warned not to touch or to play with chipmunks or other rodents in or around regions in which sylvatic plague has been demonstrated.

5. The Forest Ranger should immediately report noteworthy rodent mortalities to headquarters in order that the nature of the epizootic may be determined.

6. In recognition of the inherent danger in transferring plague to human habitations through wild rodents used as cage pets, the California State Department of Public Health in an official order dated September 14, 1937, prohibited the shipment or sale of chipmunks, Golden mantled squirrels, or other wild rodents unless these animals are held in quarantine for 2 weeks prior to shipment or sale. Consignments of rodents trapped in areas in which an animal has been found to be plague infected must be destroyed. It is recommended that similar steps be taken by the health officers in other states.

II. RODENT PLAGUE (ANATOMICAL AND LATENT)

(1) *California*—The experiences of the past 3:

years confirmed previous observations that rodents with anatomical lesions of plague may be discovered late in the season in regions in which the infection is operative in epidemic distribution. Thus it is by no means surprising that, late in September and October, 2 dead and 1 sick Beecheyi squirrels with plague lesions were dissected in the Huntington Lake area. On the other hand, the gross examination of over 6,556 small animals between May 12 and July 10, 1937, in the Lake Tahoe area failed to detect plague. Despite the demonstration of *P. pestis* in several pools of fleas collected in the Big Bear and Barton Flats areas of San Bernardino County, no anatomically marked rodents have been found among 2,255 animals. In fact, rodent plague has not been recognized in the county. The finding of plague infections without visible lesions in Oregon squirrels during the survey activities in 1935 in Lassen County prompted a radical change of the methods dealing with the examination of wild rodents during the month of August. Pieces of spleen, liver, and lymph nodes were removed from every animal during dissection. In trying out this new procedure, the organs of from 5 to 90 rodents were placed in glass stoppered bottles carefully iced and sent to the laboratory. They were washed with salt solution, ground with sand, and a proportion of 5 to 10 per cent suspended in salt solution. Cultures on blood plates were made and, if the material was not too heavily contaminated with *B. coli* and *B. proteus*, 1 to 2 c.c. of the suspensions were inoculated subcutaneously into guinea pigs. When too heavily contaminated, the injections were made intracutaneously. It is now recognized that the pools should not include the organs of more than 10 to 15 animals. Although in no instance were plague bacilli grown in the cultures prepared from the suspensions, 13 guinea pigs injected with different pools succumbed to plague as follows:

El Dorado County—132 rodents examined

October 4: 1 pool of 7 Beecheyi squirrels, 5 chipmunks, 2 wood rats, 2 Alexandrinus rats, and 3 Golden mantled squirrels.

October 19: 1 pool of 6 tamarack squirrels (*Sciurus douglasii*). Infected fleas had been found on this species in the same area in 1936.

Fresno County—515 rodents examined—98 pools of 434 animals

September 9, 1937: 1 pool of 5 chipmunks (*Eutamias*)

September 14, 1937: 1 pool of 3 Beecheyi squirrels

October 2, 1937: 1 pool of 9 golden mantled squirrels (*Callospermophilus*)

October 2, 1937: 1 pool of 14 chipmunks

October 9, 1937: 1 pool of 1 flying squirrel (*Glaucomys sabrinus*)

October 10, 1937: 1 pool of 2 white-footed mice (*Peromyscus*)

November 4, 1937: 1 pool of 6 golden mantled squirrels

The cadavers of the flying squirrels and of the field mice were available for a painstaking examination. Neither gross nor microscopic study revealed inflammatory lesions. The plague bacillus was, therefore, present as an *inapparent, invisible infection* in an undiminished state of invasiveness; the guinea pigs injected with the suspensions succumbed to pure *P. pestis* infections in from 5 to 8 days. None of the organs of the other rodents revealed lesions on inspection at the laboratory, and the personnel of the field survey crews consisted of exceedingly well trained observers who would have readily recognized even the smallest markings of plague. The incidence of invisible *P. pestis* infection among the rodents of the Huntington area may be tentatively estimated as follows: Beecheyi squirrels 3 in 253, Golden mantled squirrels 15 in 130, chipmunks 19 in 100, field mice 2 in 9, and flying squirrels 1 in 1.

During the latter part of 1937, 233 pools prepared from the organs of 1,380 rodents shot or trapped in 15 counties of California in which sylvatic plague was known to exist failed to infect guinea pigs.

Latency as a phase of an infectious disease is a well recognized biological phenomenon. Although first established by Swellengrebel and Hoesen¹ for *P. pestis* infection in rats in Sumatra, and then by William and Kemmerer² for the same rodent in New

Orleans, it has with increasing frequency been mentioned from the sylvatic plague areas in Southeast Russia and in the Trans-Baikal by several investigators. Nikanorov (1925) and Gaiski (1926), based on careful observations, came to the conclusion that susliks (*Citellus pygmaeus*) and large gerbilles (*Rhombomys opimus*) may become carriers of the plague bacillus and thus transfer the virus from one season to another. Latent and chronic plague infection involving not less than 20 per cent of the susliks in the steppes of the Ural has been studied by Konstansov,³ and Syssine⁴ saw it in tarabagans.

The demonstration of latent plague in the rodents responsible for sylvatic plague on the American Continent is a biological process which had to be anticipated. Doubtless it would have been discovered long ago had not the laborious technical difficulties been a deterrent factor. At least, in California the examination of organ pools will greatly help to clarify the epidemiology of plague among the rodents and the occasional human infections, although the elucidation of the causes remains for the present a fascinating problem. For example, one would like to know if an invisible infection may be converted into a manifest process. Grikurov, in a recent paper from the North Caucasian anti-plague organization, presents suggestive evidence that malnutrition or other environmental conditions may act as provocative factors and transform a latent into an active process, thus serving as supplying the seeds for plague epizootics early in spring. In this connection, it must be mentioned that the plague bacilli isolated from the guinea pigs, which succumbed to organ pool injections, had in the mouse pathogenicity test the same degree of invasiveness as those cultured from infected fleas or human tissues. Approximately 12 to 24

bacilli are required to cause an infection of the mouse by the intra-peritoneal route.

Nothing is known concerning the species disposition of the rodents involved in the plague areas. Individual variations in the disposition induced by biological changes are quite important. Thus it was found by Tinker and Kalabuchov that the young *Citellus pygmaeus* are the most susceptible to plague, then the adult females, and the least susceptible are the adult males. Finally, ecological and even climatological factors affecting the nutrition and population numbers greatly influence the susceptibility and the character of the plague infections.

The Russian investigators have used skin tests and serological procedures to detect invisible plague in rodents. Grikurov⁵ found that the sera of old *Citellus pygmaeus* contained agglutinins against *P. pestis*. He reasons that the increasing immunity of the rodent population, reflected in the serum reactions, may play an important rôle in the disappearance of the epidemic. That sub-lethal infections may be responsible for a part of the population immunity is fully recognized. However, two other factors play an equally important rôle. The weeding out of the susceptibles and the hereditary transmission of the resistance of the parent rodents to subsequent generations has been proved for rats, but has not been extensively studied on squirrels and other wild rodents. In view of the recent reports by Pirie (1936) that the South African plague strains obtained from both human and animal sources reveal a steady diminution in virulence, it is obviously desirable to estimate with special care, by using quantitative methods, the degree of virulence of every strain that may be isolated from wild rodents on the American Continent.

Contrary to the belief too often held

by the laity and even by those who are familiar with certain phases of plague, an epizootic among wild rodents is by no means always followed by human *P. pestis* infections. The great foci of sylvatic plague in Russia furnish many convincing examples. During June, 1913, a severe epizootic affected the suslik population of the Astrakhan steppes in the vicinity of two villages with a population of 6,000. At least 75 per cent of the 1,243 cadavers of susliks and hares scattered over the pastures proved to be plague infected; yet no case of human plague was diagnosed. Similar situations have been observed in 1930 in the steppes of the Ural. Although the factors influencing this low transmissibility are entirely unknown, these mass observations should at least alleviate to a certain extent the fear which the presence of sylvatic plague creates among misinformed groups of people.

(2) *Idaho*—According to L. J. Peterson, Director of Laboratories, the Plague Field Laboratory and the U. S. Public Health Service survey crews examined 2,213 *Citellus armatus*. In June, Dr. C. R. Eskey, U. S. Public Health Service, in charge of Plague Suppressive Measures, demonstrated *P. pestis* by mass inoculation of tissues from 47 *Citellus armatus* secured 15 miles north of Lava Hot Springs, Bannock County.

(3) *Montana*—According to Dr. W. F. Cogswell, Secretary of the Montana State Board of Health, three traveling field laboratories (one state and two U. S. Public Health Service) examined 3,204 rodents. Dr. C. R. Eskey demonstrated *P. pestis* in the tissues of 3 *Citellus elegans* (July 23, Dillon, Beaverhead County, August 20 and 23, Cameron, Madison County). The animals exhibited lesions of plague, in fact, one (August 23) was found dead as a result of a *P. pestis* infection.

(4) *Nevada*—The detailed surveys conducted both by the California and the U. S. Public Health Field Laboratories and the examination of many rodents failed to demonstrate gross anatomical rodent plague, although infected fleas were found.

(5) *Oregon*—Dr. F. D. Stricker reports that the Oregon Mobile Laboratory examined

4,973 rodents and collected 10,903 fleas. The tissues of 1 *Citellus oregonus* shot in May in Grant County and 1 *Citellus columbianus*, Wallowa County (in June) were proved by Dr. C. R. Eskey to be infected with *P. pestis*. No new areas of sylvatic plague were discovered.

(6) *Utah*—E. H. Bramhall, Director, Division of Laboratories, reports that in June the fleas removed from perfectly healthy *Citellus grammurus* near Morgan, Wasatch County, proved to be infected with *P. pestis*. The U. S. Biological Survey discovered sick *Citellus armatus*, and subsequently the Field Laboratory secured tissues from one animal which were proved by Dr. C. R. Eskey to be infected with *P. pestis*. This epizootic was in progress in Northeastern Utah near Weber, Wasatch County.

(7) *Washington*—Dr. A. U. Simpson, Chief, Division of Laboratories, Washington State Department of Health, in submitting the report by L. J. Hughes, stresses the fact that although the examinations of 1,334 rodents and wild animals of various sorts failed to reveal gross anatomical plague, batches of 33 and 18 fleas, respectively, and 3 and 5 lice, respectively, removed from 21 and 13 *Citellus townsendi* in Adams County were found by Dr. C. R. Eskey to be plague infected. Thus the existence of sylvatic plague in one of the most northern points in the United States has been definitely established, and the nature of certain fatal epizootics among rodents during 1914-1915 and 1931-1932 may ultimately be clarified.

The survey studies conducted on a scale hitherto unknown in the annals of sylvatic plague on the North American Continent have amply confirmed the suspicion that the infection is widely distributed, but difficult to recognize without mass inoculations of tissues or fleas. To the list of rodents that suffer from spontaneous plague previously reported must now be added the Sierra Nevada flying squirrel [*Glaucomys sabrinus luscivus* (Bange)] and Golden mantled squirrel [*Callospermophilus chrysodeirus chrysodeirus* (Merriam)]. Since infected fleas have been removed from the Townsend squirrel (*Citellus townsendi*), presumably this rodent is also a host for the plague bacillus.

III. SURVEYS ON INFECTED FLEAS

It has always been a disconcerting fact that in a number of instances the epidemiology of human plague (1 case 1933, 3 cases 1936) could not be explained since the anatomical examinations of the rodents shot or trapped in the vicinity of the cases yielded negative findings. Thus the sources and the spread of the plague bacillus were shrouded in a disconcerting mystery. One should have recalled that Kitasato, the Indian Plague Research Commission, and in particular Swellengrebel and Hoesen had found many years ago that in instances where infected rodents were scarce or apparently absent, it was comparatively easy to collect plague infected fleas for adequate examination. During 1936 the subcutaneous inoculations of suspension of crushed fleas removed from wild rodents into guinea pigs were conducted on a large scale. A number of important findings deserve recording:

32 fleas from	2 normal Beecheyi squirrels
14 fleas from	9 normal Golden mantled squirrels
29 fleas from	5 normal Beecheyi squirrels

Placer County—Infected area proved since 1936; 1 of 71 pools with 3,411 fleas collected from 3,537 rodents; 70 fleas from 107 normal chipmunks infected guinea pigs with plague.

San Bernardino County—No rodent plague demonstrated. Twelve of 76 pools including 4,808 fleas from 2,255 rodents infected guinea pigs.

44 fleas from	11 normal Beecheyi squirrels
78 fleas from	28 normal Beecheyi squirrels
52 fleas from	13 normal Beecheyi squirrels
78 fleas from	102 normal chipmunks
6 fleas from	7 normal Fisheri squirrels
260 fleas from	20 Golden mantled and 31 Fisheri squirrels
56 fleas from	27 Golden mantled squirrels
213 fleas from	33 normal Fisheri squirrels
194 fleas from	74 Golden mantled squirrels
521 fleas from	79 miscellaneous rodents
491 fleas from	43 Fisheri squirrels
30 fleas from	36 Golden mantled squirrels
12 fleas from	76 white-footed mice
5 fleas from	6 wood rats (<i>Neotoma</i>)

San Mateo County—During 1936, 18,729 fleas were collected from 802 rodents in 155 pools. Since it was impractical to make the necessary tests, the vials with the fleas in salt solution were stored in a refrigerator at 3° C. for 10 to 11 months. When the pools were tested in 1937, 6 were found to produce typical plague in guinea pigs. Careful field studies showed that the infected fleas had been collected from rodents present in burrows which harbored diseased rodents 20 years ago. Repeated search for infected squirrels during the past 5 years invariably resulted in negative findings. The persistence of clandestine foci of plague in close proximity to human habitation was an interesting discovery. Although the viability of *P. pestis* in stock cultures for many years is well known, the fact that the bacteria remained alive in the dead fleas soiled with a variety of microorganisms (*B. coli*, *B. proteus*, cocci,

etc.) held at ice box temperature is specially noteworthy.

Santa Cruz County—Twenty pools consisting of 5,345 fleas from 789 rodents yielded entirely negative results despite the fact that, in 1936, 7 of 35 pools consisting of 2,154 fleas proved to be infected.

(2) *Idaho*—Dr. C. R. Eskey demonstrated by guinea pig inoculations *P. pestis* from triturating 56 fleas and 1 louse from 7 *Citellus armatus* shot on June 17, 20 miles north of Lava Hot Springs, Bannock County.

(3) *Nevada*—In an extensive series Dr. C. R. Eskey has proved the existence of infected fleas in various counties of Nevada as follows:

10 fleas from 19 chipmunks
(*Eutamias frater*) in
Ormsby County

36 fleas from 52 chipmunks
(*Eutamias frater*) in
Ormsby County

95 fleas from 46 chipmunks
(*Eutamias frater*) in
Ormsby County

106 fleas from 55 chipmunks
(*Eutamias frater*) in
Douglas County

318 fleas from 200 chipmunks
(*Eutamias frater*) in
Douglas County

134 fleas and 4 lice from 3 Beecheyi squirrels in Ormsby County

(4) *Oregon*—Infected fleas were found by Dr. C. R. Eskey as follows:

56 fleas from 36 Oregon squirrels in Lake County

264 fleas from 56 Columbia squirrels in Wallowa County

(5) *Utah*—The fleas (25) collected from 2 healthy *Citellus grammurus* in Morgan County were found to be infected, while the insects removed from diseased squirrels in Wasatch County proved to be non-infected.

(6) *Washington*—Pools of fleas and lice collected from *Citellus townsendi* in Adams County proved to be infected.

Even a cursory analysis of the data on fleas demands a brief discussion. Although epidemiological and experimental data fully attest to the vital rôle of the flea in the propagation of plague both among the rodents and man, it is rarely appreciated that the vectors carrying *P. pestis* are not regu-

larly capable of transmitting the parasite.

In 1915 Swellengrebel and Hoesen, while studying plague during inter-epidemic months, made the important discovery that in 18 instances the presence of plague was demonstrated by means of the inoculation of material from 15,279 triturated fleas taken from 3,230 rats. No human cases of plague were observed during the same time. More recently George and Webster (1934), in their inquiry into plague in the Cumbum Valley in South India call attention to the important difference between *infected* (pestiferous) and *infective* (pestigenous) fleas, and that the distinction has not been sufficiently emphasized. The mere sucking of blood carrying *P. pestis* by the flea does not necessarily render it infective, *i.e.*, likely to transmit infection. Even under the most favorable conditions, only an occasional infected flea becomes blocked and capable of infecting. Neither the total number of fleas found on the rodents, not even the number of infected fleas, but the number of infective fleas is of prime importance. The physiologic-pathologic processes, which lead to the blocking of fleas, are greatly influenced by the climatic factors. Thus during the hot season very few infected fleas become infective.

Doubtless similar observations have been made by Girard (1935) in Madagascar, who tried to explain the demonstration of infected fleas on healthy rats by assuming the presence of a bacteriophage either in the vector or in the rodent.

The problem concerning infected and infective fleas has primarily been studied in connection with the vectors found on rats. The pertinent question arises: Are the facts applicable to sylvatic plague? In order to answer it, one must search the extensive field and laboratory studies published by the Russian workers in articles not readily

accessible. One realizes that the evidence—in particular the vector efficiency—regarding the fleas is by no means as well worked out as that concerning their hosts. Each rodent has its own hordes of fleas and the rôle as vectors must be analyzed individually. The studies of Golov and Ioff (1925–1927) are in this connection quite important. These two Russian workers experimented in detail with the fleas (*Oropsylla silantiewi*, *Ceratophyllus tesquorum* and *Neopsylla setosa*) of the Siberian marmot (*Citellus pygmaeus*), and the pulicidae (*Ceratophyllus mokrzeckii* and *Ceratophyllus consimilis*) of the field mouse (*Mus musculus* and *Mus musculus Wagneri*). Although nearly all types of fleas were capable of transferring plague from rodent to rodent when used in large numbers, in one test as few as 3 insects infected the experimental animals. Less successful was Bytchov (1935) who fed 624 fleas collected from tarabagans, marmots, and rat-hares (*Ochotona daurica*) on different experimentally infected rodents. In 61 individual experiments using as many as 40 fleas, not one transmission succeeded. He emphasizes the fact that transfer of the plague virus will not take place until at least a partial blocking of the proventriculus and ventriculus of the flea has taken place. In fact, a wild rodent flea infects quite irregularly either immediately after sucking infected blood or later when massive growth of the plague bacilli leads to obstruction of the proventriculus. Already in 1928 Bytchov and Borzenov by using a cultural method in seeding the intestinal tube of dissected fleas on agar noted that normal insects with no signs of “blocking” of the stomach yielded positive cultures. Tumanski and Poliak investigated 1,797 fleas recovered from a marmot nest in November; 5 fleas yielded *P. pestis* although none was blocked.

Based on these and similar observations, the Russian workers list the various modes of transmission of plague from rodent to rodent in the following order of importance:

1. Crushing of infected fleas with the teeth, infection through the mucosa of the buccal cavity with subsequent involvement of the lymph-nodes of the neck.

2. Scratching and rubbing of infected fleas, rarely fecal droppings into superficial skin wounds or abrasions.

3. Through the bite of the flea with a soiled proboscis following the sucking of blood from a diseased rodent.

4. Later as an infective-blocked insect.

Analyzing the epidemiology of sylvatic plague in its relation to man, the observers in Saratov and Trans-Baikal conclude that immediate contact with the sick or dead rodent leads to bubonic plague, while flea transmission is infrequent. The danger represented by individual fleas, therefore, appears more limited than was originally believed. Aside from serving as vectors, the wild rodent fleas act, according to the observations of Golov and Ioff, Tumanski and Poliak,⁶ and Evseeva and Firsov⁷ as “preservers” of plague infection in the burrows. Thus infected fleas obtaining an occasional meal may be alive for many months, particularly in regions where the moisture of the environment is high but the temperature low. Systematic studies concerning the influence of the “microclimate” and the burrows both on the preservation and in particular on the development of infective fleas from merely infected insects have not been made. Without a thorough understanding of the ecology of the species of fleas infecting the different rodents, it is impossible to evaluate the vector efficiency and the present-day risk of sylvatic plague to man. However, from the available information, it is

clearly demonstrated that the problem of infected versus infective flea applies also to the pulicidae of the wild rodents. In all probability, the vector efficiency plays an important rôle as has been pointed out by Eskey.

Experimental studies by Iofi and Pokrowskaja leave no doubt that the fleas of human habitations (*Pulex irritans*, *Ctenocephalus felis*, and *Ctenocephalus canis*) become readily infected, and may carry the bacteria in the intestinal tract for many days. They remain permanently infected until death but never become infective.

In considering the rôle of the infected flea, one important observation by Bytchov must not be overlooked. Eight guinea pigs used in the feeding experiments with plague infected fleas discussed in the preceding paragraphs, survived when again bitten by 10-40 plague fleas; 1 month later all 8 animals proved immune against a dose of *P. pestis* fatal to controls. These observations and those by the Indian Plague Research Commission on rats suggest to him the realization that also under natural conditions rodents bitten by infected fleas may not succumb but become actively immunized. This hypothesis deserves experimental investigation for the following reasons:

Although the flea with a stomach capacity of 0.5 cu. mm. of blood may ingest at least 5 bacilli from a rat with 10,000 plague bacilli per c.c. in the blood stream. No estimates concerning the number of bacilli which are regurgitated from a "blocked" flea are available. In fact, it is reasonable to surmise that the viscous consistency of the "block" may contribute a variable number of *P. pestis* to the inoculum. Of interest, in this connection, are the findings of Borzenov who bacterioscopically counted 70,112 and 1,026,921 plague bacilli, respectively, in 3 infected fleas. There is no standard method of testing viru-

lence except the procedure by Sokhey on mice. At least 12 to 24 bacilli are required to cause an infection by the intraperitoneal route. Probably a considerably larger number is needed to infect by the cutaneous route and, furthermore, the infective dose may vary with the species of rodent (in some recent experiments on Richardson squirrels at least 250). Finally, the ability of the flea to become infected will depend on the number of plague bacilli in the blood stream of the sick or dying rodents. Nothing definite is known regarding this phase of the problem. Feeding of wild rodent fleas on plague infected guinea pigs may not imitate the conditions as they occur in the burrows.

The absence of infected fleas collected from squirrels dead with septicemic lesions of plague still requires an explanation. Preliminary observations indicate that the method of collecting the fleas with the aid of gaseous antiseptics may not be responsible for the discrepant findings, but other important, as yet unknown, factors affecting the host-parasite relationship in the rodent play a rôle.

Both the early reports and the more recent observations emphasize the fact that handling of sick and dead rodents, occasional bites and similar accidents preceded the appearance of bubonic or carbuncular human lesions. A perusal of the 55 American case histories dealing with plague infections of supposed squirrel origin fail to report fleabites in about 40. It will always remain a matter of conjecture as to the actual number of cases which were caused by fleabites, since the allergic cutaneous response of man to those insects is decidedly different. As a rule, the bite of wild rodent fleas (*Oropsylla*, *Hoplopsylla*, etc.) produces no reaction, while the insects of human habitations are responsible for the purpura pulicosa. Certain species of fleas may be

efficient vectors of *P. pestis* between wild rodents, yet they rarely attack man. A fact which is quite often overlooked.

SCIENTIFIC INVESTIGATIONS

1. *Vector Efficiency and Plague Transmission*—Dr. C. R. Eskey will report on his exceedingly important studies at the forthcoming meeting of the Western Branch of the American Public Health Association at Portland, Oregon.

2. *Rodent Studies*—Dr. Walter M. Dickie and E. T. Ross of the California State Department of Public Health approved and supported, during the summer of 1937, a research program by Dr. Tracy I. Storer on the native rodent population in the Tahoe area. Fletcher G. Palmer, M.S. (Mammology), was engaged to conduct the studies on rodents. As might be anticipated, a 6 months program of study merely paves the way for further work. The technics which had to be developed, in particular with respect to the trapping operations, required a great deal of time and ingenuity, and it is obviously necessary to continue the investigations for a number of years and not merely as seasonal studies. The results may be summarized as follows:

a. The rodent population in a plague area in the California mountains is quite large, and varies from 27 to 117 individuals per acre. Depletion of the rodent populations by trapping small areas is followed within 2 months by recovery to a considerable fraction of the original numbers.

b. Rodent control over a narrow belt is soon followed by re-invasion from adjacent non-poisoned areas.

c. Experimental selection of most preferred baits may lead to more effective operations.

d. The most abundant and most catholic rodents, in respect to habitat, are commonest in human habitations.

e. Capture, marking, and defleaing of wild rodents is thoroughly practicable. Limited use of this technic resulted in recapture of a number of chipmunks and squirrels from which fleas, acquired by the rodents after first release, were removed. *Thus, for the first time it is believed, data were obtained on the rate at which rodents re-acquire ectoparasites within short intervals after being defaunated.*

f. These results show that fleas are present in rodent territory in addition to those actually on the rodents. It is not unlikely that the temporary reduction of rodent hosts (through control measures) may expose human beings to greater chance of becoming host to fleas, particularly where rodent burrows and nests are in close proximity to human habitations.

g. Live trapping operations show that larger numbers of fleas are obtained by defaunating rodents captured in live traps than from rodents killed in snap traps.

3. *Entomological Studies*—As a part of the research program on the rodent population, Dr. M. A. Stewart with the assistance of Frank Tatum conducted a number of preliminary entomological studies, summarized as follows:

a. During the season, the 3,137 fleas collected from 2,032 rodents may be roughly classified into 14 genera and 21 species. The identifications are not as yet completed.

b. The incidence of flea infestation is quite variable and apparently not determined by host size.

c. A seasonal incidence in flea infestation has been observed. Shrews (*Sorex vagrans amoemus*) become more heavily infected as the season progresses; the Beecheyi squirrels show a marked increase in the magnitude of flea infestation beginning in August and still increasing in October. The flea indices on chipmunks (*Eutamias*) indicate a rise in July with a peak in

the second week in August. The Sierra Nevada chickaree differs from all other hosts in that its flea index is higher from the second week in June to the last few days in July, than during the remainder of the season during which the investigations were conducted.

d. There are indications of regional differences in flea populations of different hosts in different areas of the territory investigated.

e. A more or less constant flea population level is maintained on a rodent over a period of time, not great enough to involve factors capable of exerting an influence upon the bionomics of the fleas sufficient to bring about a change in the size of the general population. *It is quite obvious that a rodent, which has been freed of all fleas, will acquire what appears to be the normal number for that particular season of the year in a very short time, possibly within a few hours.* It is equally demonstrated that these fleas in question are active in seeking hosts. This information is very pertinent to the execution of sylvatic plague control procedures. *If rodents move into a focus of plague after rodent control measures are effected and before the fleas have died from starvation, which may require a very considerable period of time, they may be readily attacked by infective fleas and thereby maintain the focus of infection.*

f. The preliminary observations indicate that the flea indices of rodents

surviving the control operations are *not significantly different* from those collected from rodents taken in non-poisoned areas. Furthermore, taking into consideration the seasonal incidence of flea populations, there seems to be no increase in flea indices manifested after some time has elapsed following the distribution of poison.

g. Experimental studies have shown that methylbromide, administered at the rate of 10 c.c. per burrow opening, is very efficient in controlling both burrow rodents and their fleas. This fumigant, of course, must be used with the customary care accorded to all highly toxic gases.

NOTE: The Chairman of the Committee begs to express to the Executive Committee, the Health Officers, Dr. C. R. Eskey, and the U. S. Public Health Service his appreciation for the continuous assistance he was privileged to receive during the collection of data presented in the report. The liberal support given by Dr. W. M. Dickie and the State Department of Public Health has greatly broadened the knowledge in a very complex field of epidemiology; it has enabled both Dr. Tracy I. Storer and Dr. M. A. Stewart to collect information along the lines in which they are experts.

Preventive Medicine

THE object of preventive medicine is to prevent not only the spread of disease, but its unnecessary occurrence,

to remove its occasion, to save the time which it loses, and the suffering which it causes.—Sir George Newman.

Contributions of Edward Jenner to Modern Concepts of Heart Disease

O. F. HEDLEY, M.D.*

*Passed Assistant Surgeon, U. S. Public Health Service,
Philadelphia, Pa.*

WHEN the name of a versatile person becomes associated with an outstanding achievement, posterity often fails to give due recognition to his other gifts and accomplishments. Edward Jenner is ranked among the immortal figures in medicine because he first successfully introduced preventive inoculation as we know it today. Because his name is associated with the discovery of vaccination against smallpox we are apt to lose sight of some of his other contributions to medicine.

Had Edward Jenner never observed the vicarious relationship of cowpox to smallpox he would still have been remembered among the great clinicians of his day—the Hunters, the Pitcairns, Parry, Heberden, Rush, and others. Not only was he a distinguished physician but he also made botanical and ornithological observations, played on the violin and flute, and wrote occasional poems.¹ John Hunter, his tutor and friend, a naturalist of no mean ability, although generally remembered for lifting surgery above the plane of the barber surgeons, attempted to induce him first to become a biologist and later a teacher of medicine. On

Hunter's recommendation Jenner was appointed to prepare and examine specimens which Captain Cook brought back from the South Seas, and was subsequently offered the position of naturalist to one of these expeditions.²

When Jenner, while a general practitioner in Berkeley in 1771, overheard a young woman remark "I cannot have that disease, I have had cowpox," he began considering the possibility of conferring an artificial immunity against smallpox and went to John Hunter for advice. Hunter more than atoned for his previous suggestions by counselling him²: "Don't think, try; be patient, be accurate."³

RELATION OF CORONARY ARTERY DISEASE TO ANGINA PECTORIS

In 1768 Heberden described the symptom complex which he called "angina pectoris."⁴ His ideas concerning the nature or cause of this syndrome were quite hazy. In May, 1777, John Hunter in a letter to Jenner briefly mentioned symptoms of a cardiovascular disease, from which he had suffered since 1773. In August he went to Bath for treatment. Here Jenner saw him and concluded that Hunter was suffering from angina pectoris. So greatly concerned was he that he wrote to Heberden in 1778 about

* From the Office of Heart Disease Investigations, National Institute of Health, U. S. Public Health Service. Branch Office: 133 So. 36th Street, Philadelphia, Pa. Published by permission of the Surgeon General.

their common friend's condition. In this letter he mentioned two dissections on subjects who had died of angina pectoris in which the chief morbid findings were thickening of the coronary arteries. Heberden had failed to note this, only finding sclerotic plaques in the aorta. Jenner discussed the difficulties of dissecting these vessels due to their often being embedded in fatty tissues. He states:

The importance of the coronary arteries and how much the heart must suffer from their not being able to perform their functions (we cannot be surprised at the painful spasms) is a subject which I need not enlarge upon, therefore shall only remark that it is possible that all of the symptoms may arise from this one circumstance. Should it be admitted that this is the cause of the disease I fear the medical world may seek in vain for a remedy.¹

John Fothergill, in 1776,⁵ had described coronary sclerosis in a patient who had died of angina pectoris in 1775. He did not definitely associate the condition of the coronary arteries which "from their origin to many of their ramifications were become as one piece of bone" with the clinical manifestations. Caleb Hillier Parry, who in 1799 wrote a very clear account of the relationship of angina pectoris to coronary disease, conceded the priority of this conception to Edward Jenner.⁶ In the introduction Parry includes a letter from Jenner, illustrative of a subtle sense of humor as well as confidence in his views concerning the underlying cause of angina pectoris. It reads in part:

The first case I ever saw of Angina Pectoris, was that in the year 1772, published by Dr. William Heberden, with Mr. Hunter's dissection. There, I can almost positively say, the coronary arteries of the heart were not examined. Another case of a Mr. Carter, at Dursley, fell under my care. In that, after having examined the most remote parts of the heart, without finding any means for which I could account for his sudden death, or the symptoms preceding it, I was making a

transverse section of the heart pretty near its base when my knife struck against something hard and gritty, as to notch it. I well remember looking up at the ceiling, which was old and crumbling, conceiving that some plaster had fallen down. But on a further scrutiny the real cause appeared: The coronary arteries were become bony canals. Then I began a little to suspect. Soon afterward Mr. Paytherus met with a case. Previously to our examination of the body, I offered him a wager that we would find the coronary arteries ossified. This however proved not to be exactly true; but the coats of the arteries were hard, and a sort of cartilagenous canal was formed within the cavity of each artery, and there attached, so however to be separable as easily as the finger from a tight glove. We then concluded that malorganization was the cause of the disease. . . . The appearance in Mr. Bellamy's case gave me the idea that the disease arose from a determination of the vasa vasorum, and that the concretions were deposits from the coagulable lymph or other fluids, which had oozed on the internal surface of the artery.

The last two cases strongly suggest previous acute thrombotic coronary occlusion, in the first of which there was evidently a re-canalization of the artery.

Due to the fear of the effect it might have on his friend Hunter, Jenner did not further pursue his studies or publish these observations. They were subsequently confirmed by a postmortem examination on Hunter who died suddenly while arguing with colleagues at a hospital board meeting in 1793, some 15 years later. A necropsy was performed by Sir Everard Home, who wrote Jenner:

I am assured that you were sincerely afflicted at the death of your old and most valuable friend; whose death, although we all looked for it was more sudden than could have been imagined. It is singular that the circumstance you mentioned to me and you were always afraid to touch upon with Mr. Hunter should have been a particular part of his complaint, as the coronary arteries of the heart were considerably ossified.⁷

Among the other findings of interest in this necropsy were two white plaques, on the under surface of the

left auricle and ventricle, entirely distinct in color from the rest of the heart. These could well have been the results of former myocardial infarctions, possibly occurring at the outset of symptoms a score of years previously. The mitral valves and the aortic valves were extremely thickened, and in places ossified—probably the result of sclerotic processes, although suggestive of an old rheumatic infection. The aorta was dilated, giving the appearance of an incipient aneurysm. The internal membrane of the aorta was studded with opaque white spots raised higher than the general surface.⁸ These findings are consistent with those of syphilitic aortitis, and are consonant with the view that Hunter had syphilis, said to have been acquired during one of the operations on aneurysms, for which he was noted, or during some of the self-inoculation experiments with material from persons infected with venereal diseases. The changes in the coronary arteries were apparently of sclerotic origin, since these vessels were "hard as bony tubes." Changes in the coronary arteries due to syphilis do not usually extend more than one to two centimeters from the orifices.

Jenner's views form the basis for the present-day concept of angina pectoris. The current teaching is that this condition is due to a relative myocardial ischemia occurring as a result of acute coronary arterial insufficiency. The mechanism of these attacks is still imperfectly understood. Nervous influences play an important rôle. In at least 75 per cent of cases, significant changes are found in the coronary arteries. Coronary arteriosclerosis is by far the most common lesion, although atresia of the orifices of these vessels as a result of extension of syphilitic aortitis, rheumatic coronary arteritis, emboli from various causes, and other less frequent factors are sometimes responsible. Angina pectoris

has been known to occur as a result of anemia, and cease when the anemia has been overcome. The opinion Jenner expressed concerning the progressive nature of the underlying changes was prognostically prophetic, for medical science still waits methods for preventing coronary artery disease or satisfactorily postponing its more serious consequences.

RHEUMATIC HEART DISEASE

About 1778, Jenner was instrumental in forming a society which had for its objective improvement in medical science. It was also intended to promote conviviality and good fellowship. This small medical society usually met in the Fleece Inn at Rodborough. Jenner was a member until about 1790. It was during these meetings that he presented a paper on angina pectoris, which later formed the basis of his friend Parry's book on that subject.¹

Edward Jenner was among the first to note the relationship between rheumatic fever and heart disease. According to the records of this society, on July 29, 1789:

"Mr. Edward Jenner favored the Society with remarks on a disease of the heart following Acute Rheumatism illustrated by Dissections." This paper, together with the one on angina pectoris and others, fell into the hands of some of its members and he could never recover them. Baron, one of his earliest biographers, states:

I have heard him lament the loss of one of them in particular. It contained observations concerning the diseases of the heart, which frequently come on during attacks of acute rheumatism, and lead to enlargement and disorganization of the part. This formidable disorder had very much escaped the notice of medical men. Jenner's observations were original and had they been published at the time they were first communicated to the Society, his claim to priority could not have been set aside as it has been since that time by other writers.

On January 10, 1805, evidently wishing to establish claim to the originality of this observation, he wrote to Dr. Caleb Hillier Parry:

A neighbor of mine died yesterday, from a disease of the heart which followed two or three attacks of acute rheumatism. You may probably remember a paper of mine that was given at the Fleece Medical Society on this subject. This and my other papers are in your possession. If you could be good enough to convey them to me I should be extremely happy in regaining them particularly that I now allude to, as I am confident that many a life is lost by not shielding the heart at the going off of acute rheumatism. . . .

As there is no record of the return of this manuscript it seems evident that it was lost.

The claim for Jenner's priority in noting the relationship between rheumatic fever and heart disease is not as clear as that of the coronary basis of angina pectoris. According to Hope,¹⁰ David Pitcairn in 1788 taught that persons subject to rheumatism were attacked more frequently than others with an organic disease of the heart which he called rheumatism of the heart. Mathew Baillie¹¹ in a footnote in his second edition of *Morbid Anatomy of Some of the Most Important Parts of the Human Body*, published in 1797, gives Pitcairn credit for discovering the relationship between acute rheumatism and heart disease. In a later edition he states¹²:

Dr. Pitcairn observed this in several cases and should be considered as the first person who made this important observation. Its accuracy has since been confirmed by different individuals of high professional character, so that it may now be regarded as an established pathological fact.

These editions were dedicated to Pitcairn. In the first edition, published in 1793 and dedicated to Sir George Baker, no mention is made of this relationship.

Pitcairn, who incidentally was the son of Major John Pitcairn, who was

killed leading the British forces at the Battle of Bunker Hill, never published these observations. In at least one obituary notice he was given credit for being the first to associate acute rheumatism with heart disease. One states that he was the first to note the connection between rheumatism of the external parts and certain affections of the heart which he communicated to Dr. Baillie who wrote concerning it.¹³ Pitcairn was by nature a very shy person and once stated that the reason he never wrote was because he did not wish "to contradict seven years hence" his present opinion. One obituary writer commented concerning him "Such rigid abstinence from anything like authorship is not to be defended, particularly among the higher orders of physicians, because it may be extended to the rejection of every project for the improvement of their art."¹⁴

Although Baillie mentions acute rheumatism as a cause of morbid changes in the heart, it remained for Dundas, in about 1806, first to describe clinical cases of acute rheumatism with cardiac manifestations, proved later by postmortem examinations. These observations were published in 1812.¹⁵ He stated that as early as 1770 he had noted this relationship. Of the 9 cases he reported, 7 were dead and the 2 surviving cases offered poor prognoses. All of his patients were young individuals, only 2 over 22 years. In all the cases he had seen the disease followed one or more attacks of rheumatic fever. In 1 case the affection of the heart had appeared at the commencement of the acute rheumatism. Usually it attended a migrating polyarthritis and ran a course of a few months, ending in dropsy. In his description of the morbid anatomy, pericarditis and cardiac enlargement seemed to be the most prominent features, although in 1 case involvement of the mitral valve was inferred.

Irrespective of whether Edward Jenner was the first to note the relationship between acute rheumatism and heart disease, there is little doubt that he was among the first to conceive it. Jenner's and Pitcairn's observations were made independently. Jenner was at that time residing in Berkeley.¹⁶ Pitcairn lived in London. There is no evidence that they were then acquainted. Pitcairn was John Hunter's physician, and later they belonged to the same medical society in London. Although the manuscript was lost, there seems little question that Jenner was the first to write upon this subject. Since he supported his observations with necropsy specimens, which probably took some time to collect, it is not unreasonable to believe that he was the first to offer objective proof of the nature of rheumatic heart disease.

Survey of Belgian Health Services

IN coöperation with the Belgian Ministry of Health, the Health Committee of the League of Nations will make a survey of health conditions of the population and of the equipment,

organization, methods and efficiency of the health services in Belgium.

Professor Parisot, of Paris, is chairman of the committee appointed to make the study early this summer.

Alum Precipitated Toxoid for the Prevention of Diphtheria

ARCHIBALD S. DEAN, M.D., DR.P.H., F.A.P.H.A., AND
SAMUEL HYMAN, M.D.

*District Health Director; and Assistant District State Health
Officer, New York State Department of Health,
Buffalo, N. Y.*

THIS favorable field experience with one dose alum precipitated toxoid for the prevention of diphtheria is presented in view of the fact that the immunizing value of one injection of the product has been questioned. It is obviously desirable to produce immunity by one treatment, if possible.

In 1931, Glenny and Barr¹ described the complete precipitation of diphtheria toxoid by alum to produce a slowly absorbable antigen. In 1932, Wells, Graham, and Havens reported very favorable indications of immunity in guinea pigs and in children from the single injection of such an antigen.² Since August, 1935, alum precipitated toxoid has been widely distributed in upstate New York by means of the State Department of Health laboratory supply stations.

Seven months prior to such distribution an opportunity was presented for a trial of the product in Chautauqua County in the southwestern part of New York State. The Buffalo district staff of the State Department of Health assisted local health officials in the control of an epidemic of 17 cases of diphtheria with 3 deaths in rural Chautauqua County in December, 1934, and January, 1935. Twelve of the cases and all of the deaths occurred in 1935.

Chautauqua County, with an area of 1,069 square miles, had in 1930, 127,745 people, of whom 63,500, or 50 per cent, lived outside the two cities. The county, exclusive of the cities, has been relatively free from diphtheria. During the 10 year period 1925 to 1934, inclusive, the cases of diphtheria per 100,000 population in upstate New York urban areas of 2,500 population and over; rural areas of less than 2,500 population; and Chautauqua County, outside the cities were 40.3, 23.1, and 12.3, respectively. For the same period of time the death rates per 100,000 population for the above named areas were 3.1, 2.0, and 1.1, respectively. Following the epidemic, the rates in Chautauqua County, exclusive of the cities, again became relatively low. In the county outside the cities in 1935 there were 4 cases of diphtheria in addition to the 12 in the epidemic; in 1936 there was no case, and in 1937 there was 1 case, with no deaths. During 1936 and 1937 the cases per 100,000 population in upstate New York urban areas, rural areas, and Chautauqua County, exclusive of the cities, were 4.1, 4.4, and 1.5, respectively. The corresponding death rates were 0.4, 0.5, and 0. None of the Chautauqua County diphtheria occurred among persons who had received alum precipitated toxoid.

The diphtheria immunization status of rural Chautauqua County is indicated in part by the fact that a total of 1,316 or 28 per cent of the estimated population under 5 years of age, in the county outside the two cities on January 1, 1935, was officially reported to have had two doses of unmodified toxoid or three of toxin-antitoxin.

The intracutaneous test of susceptibility to diphtheria toxin was given in January and February, 1935, to 1,552 persons, with age recorded, in the epidemic area to determine whether or not they needed immunization. The Schick material which was used for the test in the left forearm and for the control of heated toxin in the right forearm was produced by the Division of Laboratories and Research of the New York State Department of Health. The arms were read after an interval of from 5 to 7 days. The age distribution of the 1,552 persons was as follows: under 5 years, 21 per cent; 5 to 14 years, 68 per cent; and 15 years and over, 11 per cent. Ninety-nine per cent of the children under 5 years of age; 70 per cent of those age 5 to 14 years; and 1 per cent of the persons age 15 years and over, who were Schick tested, had previously received unmodified toxoid or toxin-antitoxin.

Thirty-seven per cent of the 466 individuals tested who had never received toxoid or toxin-antitoxin were Schick negative, as were 85 per cent of 296 who had obtained two injections of unmodified toxoid 1 to 4 years previously, and 87 per cent of 790 who had received three treatments with toxin-antitoxin 1 to 10 years earlier.

Alum precipitated toxoid prepared by the Division of Laboratories and Research of the New York State Department of Health and meeting the standards of the National Institute of Health, was administered to 620 persons, of whom 442 were Schick posi-

tive and 178 had not been Schick tested. One dose of 1 c.c. of the material was injected subcutaneously on the outer side of each left upper arm. A nodule remained in the arm usually for weeks, but no undue reactions or abscesses were reported.

At 4, 16, and 28 months after the administration of the toxoid, Schick tests were given to as many as possible of the 620 persons who received the product. The procedure was the same as described for the preliminary intracutaneous test of susceptibility to diphtheria toxin. There were 401 individuals Schick tested at 4 months, 385 at 16 months, and 246 at 28 months. The dispersion of the population throughout 7 townships made repeated assemblage difficult. The persons who were Schick tested are considered to be random samples of the original 620 given precipitated toxoid, as each time all who could be induced to appear were tested.

It is probable that the small quantity of diphtheria toxin in the Schick material produced some immunizing effect. Among the 620 persons given alum precipitated toxoid there were 92 who received a total of four Schick tests, 211 who had three, 189 who had two, 95 who obtained one test, and 33 who had none. The 95 persons who had only one Schick test and the 33 who had none were the persons who failed to return for testing after they had had the precipitated toxoid.

Among 159 individuals who were Schick negative 4 months after having received 1 c.c. of alum precipitated toxoid, 152, or 96 per cent, remained negative 28 months after they obtained the toxoid. The percentage is nearly as high—94 per cent—among 69 persons who were known to be Schick positive prior to the receipt of the precipitated toxoid, and to have had no prior toxoid or toxin-antitoxin. Among 7 individuals Schick *positive* 4 months

Intracutaneous Tests of Susceptibility to Diphtheria for 620 Persons Each of Whom Received One Injection of 1 c.c. of Alum Precipitated Toxoid in January or February, 1935

after receipt of 1 c.c. of alum precipitated toxoid, 5 were Schick negative 28 months after the injection of the toxoid. The group of 7 Schick positive at 4 months included 5 who were known to be Schick positive prior to injection of the precipitated toxoid and to have had no toxoid or toxin-antitoxin previously. Three of the latter 5 had negative Schick reactions 28 months after injection of the antigen.

The results of the intracutaneous

tests of susceptibility to diphtheria for 620 persons each of whom received one dose of alum precipitated toxoid are presented in 3 tables. Table I deals with the most significant group, namely, the 302 persons who were Schick positive before obtaining 1 c.c. of precipitated toxoid and had had no prior toxoid or toxin-antitoxin. At the end of 4 months from the receipt of the toxoid 175, or 86 per cent, of 204 of the individuals tested were Schick

TABLE II

Result of Schick Test at Intervals of 4, 16, and 28 Months After Administration of 1 c.c. of Alum Precipitated Toxoid to 140 Schick Positive Individuals Who Had Been Treated Previously, but Unsuccessfully, with Unmodified Toxoid or Toxin-antitoxin

Unknown	5	3	3	100	2	1	50	0	0	0
Total	140	96	90	94±1.6*	89	80	90±2.1*	58	57	98±1.2

* = Probable error of the percentage

negative; at the end of 16 months, 162, or 87 per cent, of 187 persons were Schick negative; and at the end of 28 months, 98, or 89 per cent, of 110 individuals were Schick negative. The results for the persons under 10 years of age were even more favorable, being 92 per cent of 73 persons at the end of 4 months, 93 per cent of 71 at the end of 16 months, and 95 per cent of 58 at the end of 28 months. The increasing immunity with time may be due partly to the late effects of the alum precipitated toxoid, to Schick test toxin, or to naturally acquired immunity.

Table II shows the effect of the alum precipitated toxoid which was given to 140 Schick positive persons who had been treated previously, but unsuccessfully, with unmodified toxoid or with toxin-antitoxin. For all ages, the percentages Schick negative at the end of 4 months, 16 months and 28 months after the use of the precipitated toxoid were 94, 90, and 98. The higher Schick negative percentages in Group II than in Group I may be due to the generally readier response to antigen of persons who have had previous antigenic stimulation than those who have not.

Table III indicates the result of the administration of alum precipitated toxoid to 178 individuals who had not previously been Schick tested and had not formerly received toxoid or toxin-antitoxin. For all ages, the percentages Schick negative 4 months, 16 months, and 28 months subsequent to receipt of the precipitated toxoid were 98, 98, and 95. It was anticipated that these percentages would be higher than those for Group I because many of the Group III individuals would doubtless have been found negative if they had been Schick tested before being given the precipitated toxoid. As stated previously, 37 per cent of 466 persons in the epidemic area who had never had toxoid or toxin-antitoxin were found Schick negative. If 37 per cent of the Group III individuals who were Schick tested at 4, 16, and 28 months were already negative before they received the toxoid, the percentages made negative by treatment would be 97, 97, and 92.

CONCLUSION

It has been demonstrated that even in an area where diphtheria is not endemic a single dose of 1 c.c. of alum precipitated toxoid will give immunity

* = Probable error of the percentage

to diphtheria, as determined by the Schick test, to approximately 89 per cent of persons for at least 28 months following injection. From the public health point of view the continued use of one dose alum precipitated toxoid seems justifiable.

Public Health Courses in Texas

A COURSE in public health has been offered during the past summer at the Texas Technological College at Lubbock, sponsored jointly by the Texas State Department of Health, the Industrial Division of the State Department of Education, and the College. The course is designed for the training of public health workers and sanitation officers. Successful completion of the course and subsequent examinations lead to a certificate of completion which will be recognized by the Texas State Department of Health. Courses have included Bacteriology, and its relation to Public Health, Dairy and Milk Inspection, Elementary Studies in Water Supplies and in Sewage Disposal, Elementary Surveying, Mechanical Drawing, Control of Swimming Pools,

and Public Speaking, and are given by the regular members of the college faculty, supplemented by lecture courses from visiting specialists. These supplemental lectures have included the Organization of Health Departments and Health Units, Personnel Qualifications, Housing and Slum Clearance, Dental Hygiene, Illumination, Industrial Hygiene, Rodent and Insect Control, Epidemiology, Vital Statistics, Food and Drug Inspection, Tourist Camp and Rural Sanitation. A total of 28 persons attended the school during the first sessions, with 16 completing the course. These individuals come from 21 counties distributed throughout the state. The members of the first class have formed the Texas Association of Trained Sanitarians.

Present Status of Safety Education in Some Representative School Systems

JOHN P. SULLIVAN, PH.D., F.A.P.H.A.

Supervisor of Health and Safety, Public Schools, Boston, Mass.

THE primary purpose of a questionnaire which we sent out was to lay the groundwork for a research study which would enable us to secure better guides for the formulation of a program of safety education for Boston. Through the medium of this questionnaire we endeavored to ascertain the status of safety education programs in other cities. In analyzing the returns particular attention was given to organization, supervision, policies, and procedures. From the data so gathered we attempted a comparison of safety education in these cities with the program existing in Boston. The aim was to bring out any omissions in our own safety program. The study further intended to embody the best in policies and organization from other cities, and to determine the extent to which certain experimental procedures were used.

PROCEDURE

In order that the questionnaire might be adequate for the purpose for which it was intended, it was submitted to a superintendent, a director of educational research, a supervisor of safety education, a headmaster, and a classroom teacher for their approval. Their suggestions were incorporated into the following form which was adopted.

This form was sent to 100 representative school systems scattered through the country with a conscious con-

sideration of large and small city school systems of reputed progress in education. Despite the fact that this questionnaire required detailed information from the recipients it was favorably received and the authorities of 75 of those 100 school systems approached gave information which was complete enough to be of value.

Since the average school superintendent has been literally bombarded with blanks, forms, and questionnaires in the past 15 years it was felt that this generous response indicated a definite interest, if not enthusiasm, concerning this newer movement of safety education.

In order to consider the replies to the questionnaire on a geographic basis, the country was divided into 4 sections. Here it was found that 29 per cent of the replies came from school systems in the South; 17 per cent from the West; 28 per cent from the Northeast, while 26 per cent were from the North Central section. These replies furnished an excellent cross-section of American school systems.

In order to facilitate classifications, the data compiled from the replies were grouped in the following order: Organization, Supervision, Policies and Procedures. Under organization fell questions 1, 3, 4, 10, 11, 12, 13, 18; under supervision question 2; under policies were included questions 5, 14,

THE SCHOOL COMMITTEE OF THE CITY OF
BOSTON, ADMINISTRATION BUILDING,
15 BEACON STREET

OFFICE OF THE SUPERINTENDENT

To the Superintendent of Public Schools:

The Boston School Department is very much interested in Safety Education. We ask your coöperation in giving us the following information in regard to your school system by checking the items listed.

Name of City State

Name of Person Replying

Position of Person Replying

	(Check)	Yes	No
1. Have you a course of study in Safety instruction?
2. Have you a person assigned to supervise Safety?
3. Is Safety instruction given a definite time allotment in the school curriculum?
4. Is Safety instruction given as part of Health instruction?
5. Is Safety Education compulsory?
(a) State Law:
(b) Local School regulation:
6. Do you have police assigned for school Safety work?
(a) Full time:
(b) Part time:
7. Do you have accident data distributed to teachers?
(a) By appointed School Official:
(b) By Police Department:
(c) By Private Agency:
8. Do you have Auto Clubs in Senior High Schools
9. Do you have student Safety Councils or clubs?
10. Do you have Safety Patrols?
(a) Elementary:
(b) Junior High:
(c) Senior High:

11. Do Safety Patrols direct vehicular traffic?
(a) In Street:
(b) From Curbing:
12. Do you have Safety Patrols supervised?
(a) Local Police Department:
(b) Local School Department:
(c) Private Agency:
13. Do Safety Patrols wear some insignia—
14. Do you permit commercial Safety material to be used in the classroom?
(a) Teachers' use:
(b) Pupils' use:
15. Do you have Police protection at dismissal times?
(a) Elementary Schools:
(b) Junior High Schools:
(c) Senior High Schools:
16. Do pupils receive instruction in all schools regarding:		
(a) Crossing streets at intersections:
(b) Playing in the streets:
(c) Traffic regulations and signals?
17. Are the primary children cautioned about Safety before each dismissal?
18. Do you have a system of collecting and investigating reports of school accidents?

Any additional information that you may be able to give us regarding Safety Education such as, monographs, bulletins, reports, types of visual material and courses of study will be greatly appreciated, and any suggestions growing out of your experience will be welcomed.

In requesting this information we realize the encroachment on your time and courtesy, and we shall be very glad to forward the completed study.

Very truly yours,
JOHN P. SULLIVAN
Supervisor of Health & Safety

16, 17; while under procedures were treated the remainder, 6, 7, 8, 9, and 15.

ORGANIZATION PROBLEMS

The problem of organizing safety education varied, but there were strong

indications that the importance of this problem was recognized and that attempts were being made to meet it.

Course of Study in Safety Instructions—In compiling the replies received from the 75 cities in answer to the ques-

tion "Have you a Course of Study?" it was found that 89 per cent of the school systems had either an individual safety education course of study or one which was an integral part of their health education program. It was further found that 51 per cent had a unified independent safety education course.

These figures indicate the growing recognition of the place of safety in the curriculum; yet there seems to be a fairly large percentage whose safety courses are of a tentative nature, suggesting that this phase of education needs more consideration in some sections. From the data submitted and from a further study it would appear that the elementary safety courses for grades 1 to 6 are well advanced; that those for the junior high school (grades 7 to 9) are in the developing stage; and that very little has been done in the senior high school field.

If the final test of learning is the emergence of appropriate conduct, then the teacher of upper as well as lower grades should have some outlines of the general attitudes, the finer appreciations, the important concepts and meanings, which they wish to secure as part of the results of the safety program.

Not until such time as there is a course of study scientifically constructed for all grades can we expect a unified, graded, and progressive plan of instruction and training in safety. School administrators must face the fact that if they give guidance to teachers in all phases of the curriculum except safety, it will undoubtedly occupy a correspondingly minor position in the minds of the pupils as well as the teaching force. Teachers are entitled to as much guidance in safety teaching as in the teaching of other subjects. If safety teaching and training are among the objectives of education, then the course of study is an important vehicle.

Time Allotment:—In studying the

problem of time allotment for safety education the widest diversity was noticed—only 36 per cent of the cities answering recording a definite time allotment for the study of safety.

From the additional information sent by many cities it may be said that the majority of school systems in the country are at present combining the study of safety with other subjects in the program. However, many are now planning a course of study with the intention of including it in the curriculum with a definite time allotment. This is an interesting highlight in view of the statement often heard that no more time can be given for new work. It shows definitely that school administrators have given and are giving this new movement careful consideration and feel that it is worthy of a definite time allotment in the development of their curriculum.

Safety, a Part of Health—That safety is an important factor in the conservation of child life cannot be denied. Reputable tabulations have statistically proved that accidents are responsible for more deaths than any single disease of childhood and, limiting ourselves to children of school age, *i.e.*, 5 to 15 years of age, accidents are responsible for 1 out of every 5 deaths. Quoting from Dr. Herbert Stack, we find our justification for those cities which have made safety a part of their health or physical education program:

No one will question the fact that safety education has an important place in the school curriculum today. Educators generally agree that health and safety are basic objectives in the elementary and secondary schools; for of what avail is it to have a youngster learn the fundamental truths and the subjects of the school if he loses his health or even his life, or is seriously injured in childhood?

In view of the above quoted statement, we find that the cities answering from the various geographical divisions must have adopted this attitude. In

stating that these cities combine safety education with either health or physical education, we do not intend to convey the impression that the treatment of this subject is stereotyped to any degree; rather, it seems as if the presentation of the subject varies with the cities and their teaching staff.

Reports on School Accidents—We found that the collection and investigation of reports on school accidents has become a highly systematized part of the safety program in 60 per cent of the cities. Although this procedure was mentioned in two-thirds of the cities answering, it is doubtful whether any 5 cities returning answers go about the cataloguing of the returns in the same manner.

It was interesting to note that those cities which listed a collecting and investigating accident unit as an integral part of their safety program were among the largest cities in the country.

Safety Patrols—The safety patrol is the most universal phase of the safety program carried on in the school systems of the country. In compiling the returns it was found that of the 75 cities contacted, 89 per cent were affirmative in their reply to the question "Are Safety Patrols in Use?"

The value of school safety patrols is everywhere recognized by authorities and prominent educators. In fact, through the medium of a congressional committee this movement was given national recognition by means of an unqualified endorsement. When President Roosevelt, in May, 1936, addressed the school safety patrols convention held at Washington, D. C., he stated:

The future belongs to youth, and when youth voluntarily assumes helpful activities like yours, for the benefit of the entire community, I, for one, feel ever so much more confident in regard to the future.

There are many benefits which have been derived from these patrols. The

first benefit, of course, is the protection of the pupils. Moreover, the effect of the patrols on the character development of the pupil is an important factor. Many cities have found that these patrols stimulate the backward boys. One western city has included in the patrols boys who have been "problem children" to the police. This has proved to be an excellent idea in this city as these boys have developed the spirit of good citizenship and have ceased to be troublesome. The majority of the cities, however, require very high standards in both character and scholarship for membership in the patrols.

It has been found that knowing the theory of a subject is not always the knowing of the application of the theory. Therefore teaching safety through the patrols is teaching and practice of a theory.

Schools Having Safety Patrols—In studying the disbursement of safety patrols in the various school systems our study showed that 83 per cent of the 75 cities answering had safety patrols in the elementary schools, 71 per cent in the junior high schools, and 41 per cent in the senior high schools.

From the above it may be safely concluded that the majority of cities have found the patrols a necessity in the elementary schools, desirable to the well-being of the pupils in junior high school, and helpful to the senior high schools.

Supervision of Patrols—The patrols of the country are all organized on somewhat the same plan. They are, however, supervised in various ways.

It is impossible to give an accurate estimate of those cities using the assistance of the police, school department, and private agencies in the supervision of their safety patrols as 17 per cent of the cities were unable themselves to answer the question on supervision. This may be due to the fact that many of the

patrols are not under the immediate supervision of the board of education, but are handled by the principals of the individual districts or schools. It is also noticeable that the majority of the safety patrols in the cities are supervised by their local school departments while many of the patrols are directed by the local police department, and a very small percentage by private agencies. Some cities find it beneficial to have the police department assist the schools in their patrol work, while other cities have their school departments handle the entire patrol program.

Duties of Patrols—The duties of the patrols of the cities are uniform in that their purpose is the protection of the pupils while en route to and from school. Some cities also favor a patrol within the school and on recreation grounds. A large number of cities have a cadet or monitor system in the school buildings.

The duties in the directing of the vehicular traffic among the cities vary. The majority of the cities which state they do not allow the directing of vehicular traffic by members of the patrol, do not object to the patrol member raising his hand to warn motorists approaching a group of children who are crossing the street if he remains on the curb. They do not consider that this motion is directing or controlling the motorist, but merely calling his attention to his obligation under the law to respect the rights and safety of pedestrians at crosswalks.

It is shown that 31 per cent of the cities permit their patrols to direct traffic from the curb. This is found by many of the cities to be the most desirable way in which to assure a safe crossing for the children.

Of the cities having safety patrols, 25 per cent allow patrol members to control vehicular traffic in the street. This is a fairly large per cent in view of the fact that this is gen-

erally thought to be a poor practice.

Insignias—Of those in cities having safety patrols, 83 per cent wear insignias. The majority wear the Sam Brown belts while some wear arm bands signifying their membership in the patrol.

The use of whistles, flags, sticks, and stop signs by the cities varies. A majority of the cities absolutely forbid the use of any object in the hand, while a few allow their use to aid in patrol work.

In some instances private organizations supply the school patrols with slickers, rain capes or water-proof ponchos, and hats. One northeastern city believes that these ponchos and hats are an absolute necessity to the patrol boys on stormy days as accidents are much more likely to happen during stormy weather when visibility is low.

Conclusion on Safety Patrols—From the statistics gathered it may be said that the safety patrols are of the utmost importance. They have been tested and proved to be a decided benefit; first, to the community, in the saving of thousands of lives; second, to the youth, in character development; and third, in the training of youth in safety, so that the future, of which they shall be a part, will be years of security with freedom from the hazardous conditions existing today.

SUPERVISION

The policies pursued by the cities sending replies regarding the supervision of safety education varied. The statistical compilations show that of all the cities included in this survey, 47 per cent have their safety program supervised.

It has been the contention of prominent educators throughout the country that safety education supervision is vital to the complete fulfillment of the program. Dr. Herbert J. Stack of Columbia University pro-

posed the question, "Who shall direct the safety education of the public schools? Shall it be the Police Department, the local Safety Council, the Board of Public Utilities, the various chambers of commerce or other civic agencies?" Dr. Stack stated that his personal belief was that the direction and control of school safety activities in their entirety should be within the hands of the independent school administrations. Of course, the assistance of other agencies is acceptable, but the responsibility for the organization of the curriculum and the supervisory activities should be entirely in the hands of the superintendents and directors. He further stated that the best safety programs were those organized in cities where the superintendent designated the director of health or physical education as supervisor of safety. Justifying this statement he said:

For without the coördination that this department can help provide through its trained teachers, the safety program is likely to suffer. No program can be effective unless it is well organized with responsible teachers to carry it out.

Further additional information as it was compiled revealed much data on safety education programs and their supervision in the American school system that was interesting and worth while. However, the variety of practices discovered leads to the conclusion that more uniformity is necessary for permanent gain along these lines.

It should not be a part of this new program to call into being additions which would still further bear down upon a civic unit already so costly as the school system, rather, it should be through the changing of educational attitude and the coördination and utilization of already existing agencies that the school safety work should be made more effective.

POLICIES

The policies pursued in all cities sending replies proved interesting and enlightening. It is quite evident that the outstanding need is a philosophy of safety education. With the accepted principles from such a philosophy the movement would have a guide to steer it through its youthful stage of development. Activities, content, and devices would then be tested by approved standards, and not alone by the trial-and-error method. This problem presents another possibility for some research worker to contribute to the safety education movement.

Safety Education Compulsory—Statistical compilations show that 49 per cent of the cities in the study have safety education as a requirement either by state law or local regulations, with approximately 13 per cent having a compulsory feature in both state law and local school regulations. On the other hand, 29 per cent have only a local compulsory requirement, while 7 per cent work only under the required state law.

In answering the questionnaire, some of the cities stated that although they have no compulsory requirement in either the state law or local school regulation regarding the teaching of safety, they do encourage instruction in safety and have it given in their schools.

Our study showed that nearly half the cities contacted considered safety education absolutely essential to the welfare of the pupil. This fact is emphasized by the compulsory feature in both state and local regulation. This per cent may even be considered greater as many cities not reporting a compulsory requirement included the study of safety in their curriculum.

Use of Commercial Safety Material—Statistics showed that 65 per cent of the cities authorized the use of commercial material in the classroom. How-

ever, only one of the 75 cities permitted this material to be given to the pupils to aid them in their study of safety. In 32 per cent it was the right of the teacher alone to use commercial material while both the teacher and pupil are permitted to use commercial material in another 32 per cent of the cities.

The policies of the cities varied regarding the use of commercial material. One New England city will allow the use of commercial material only if it does not "savor of advertising," while another school system authorizes the use of American Automobile Association and National Safety Council material as these groups are "non-dividend paying organizations." One school system in the north central section permits the use of commercial material only after it has been approved by the board of education. A southern city uses all commercial material with the name of the company deleted while a western city issues to its principals and teachers each month a "safety kit" which contains various booklets, pamphlets, and posters on highway safety.

In answering this question many cities answered in the affirmative with the restriction that the material must not be of an advertising nature. It may be said, therefore, that the majority of cities do use commercial material which is of value in the safety education field, but which does not advertise a product.

Special Safety Instruction—It was found on studying the compiled returns that instructions on crossing streets, playing in streets, traffic and signal regulations were given in 87 per cent of the cities in this survey. The majority gave instructions in the schools on all these subjects, while some gave instructions in just crossing streets and playing in streets, while a

few conducted a course in only traffic and signal regulations.

These figures show that the majority of the school systems realize the importance of these three phases of safety education and include them as special topics in safety.

Primary Children Cautioned at Each Dismissal—From the statistics gathered it was found that 54 per cent of the 75 cities made it a practice to caution their primary children before each dismissal.

It is interesting to note that while some cities believe the younger children should be cautioned at each dismissal, others do not think it necessary because a well organized safety program with a definite time allotment is included in their curriculum.

PROCEDURE

The procedures used throughout were fairly uniform. But here again the schools should be guided by research and a sound philosophy.

Police Assigned for School Safety Work—It was found that police were assigned to school safety work in 77 per cent of the 75 cities contacted. A full-time schedule was listed in 28 per cent and part-time in 49 per cent.

The facilities of the police department are utilized by many of the cities in various ways. Those not assisted by the police in their safety talks and demonstrations receive the coöperation of the police in the safety patrol work and in the direction of school dismissal traffic.

The work of the police department coöperating with the school department is many-fold in its benefits. The police department can render invaluable assistance to safety education through their years of experience, by their badge of authority—not in the sense of coercion, but in the sense of prestige—and by the special training in safety work that many of these

officers receive. The statistics quoted show that the police departments are a recognized asset in aiding in the cause of school safety work.

Police Protection at Dismissal Time—Police protection of the school children at dismissal time was found to exist in 82 per cent of the cities. Of this percentage the majority stated that protection was given only at dangerous crossings. The elementary, junior high, and senior high schools have police on duty at dismissal time in 49 per cent of the cities, while 12 per cent had it just for the elementary and junior high schools; and 20 per cent had it for their elementary schools.

This study might well raise the question as to how any city can get along without police protection at dismissal time. For instance, one city reports no such protection since the formation of student patrols. It may be too that many cities not reporting here have well organized patrol systems and may not deem it necessary to request police assistance to supervise school dismissals.

Accident data distributed to teachers—Our study revealed that in the school systems of 68 per cent of the cities studied, accident data were distributed to teachers. The school department furnished records of all school accidents; the police department of all city accidents; and private agencies of accidents of all descriptions. Approximately 12 per cent of the cities collected accident information from all available sources; that is, school records, home accidents, police records, and records of private agencies; while school officials with the aid of the police department furnished data in 5 per cent of the cities. Private agencies assisted the school officials in distributing accident information in 6 per cent of the cities, while police accident data, only, are distributed in 6 per cent of the cities' school systems; private agencies

furnish all accident information in 8 per cent of the cities. Approximately 28 per cent of the cities send to their teachers only accident material regarding school accidents furnished by the school officials.

From the comments made on the questionnaire and from additional information it is noticeable that many of the cities which use only school accident data tell us that they do, however, use material furnished by the different state or city departments, such as the department of public safety and the state highway department.

Auto Clubs in Senior High Schools—Auto clubs in senior high schools were organized in 43 per cent of the cities contacted. An extensive course in safe driving was found to be given in nearly all schools that have auto clubs. Some cities do not have clubs but do include driving courses in the curriculum.

Therefore, it would seem that auto clubs in senior high schools would be of great value inasmuch as these pupils are the future operators of vehicles and a training in the proper way to handle a car would reduce the accident rate in the years to come.

Student Safety Councils or Clubs—Of the 75 cities, it was found that 69 per cent conducted student safety councils or clubs in their school systems, and of these 16 per cent stated that they had safety councils but only in scattered schools.

Through these councils the student is given the opportunity to see and solve problems that occur in his daily life. The working out of actual problems through organized activities makes the student keener and more alert to existing conditions.

Organizations—From the additional information sent to us, it was found that the majority of cities with well organized safety councils have as their main objective the prevention of accidents by the removal of the causes. The first

step taken toward this goal was the formulation of a set of "Safety Laws" to govern the conduct of students. The administration of these laws is then taken into consideration. The following procedure is used by many of the cities:

1. The objectives of the Safety Council are presented at a meeting of the faculty.
2. A faculty representative is appointed.
3. The objectives of the Council are presented at a meeting of the student body.
4. Representatives are elected from each home-room (usually two).
5. The representatives meet with the faculty member for discussion of objectives and the duties of committees.
6. A meeting of the representatives is held for the election of officers and the drawing up and adoption of a constitution.
7. A meeting of the representatives is again held for the purpose of putting the constitution into effect and to appoint committees and to explain the specific duties of each committee to its members.

These elected representatives are active members of the council and other students are called associate members. The purpose of this is to stimulate interest and to unite the entire school in a common cause.

Duties—The duties of the council are many. The committees appointed make studies of the different types of activities and observe traffic conditions in the hallways and on the stairways and at dismissals. The reports are given to the faculty representative who takes them under advisement. If the recommendations are accepted an attempt is made to adjust the situation.

It has been found by some cities that the best results are obtained when the clubs are organized by schools and not individual grades. A club organized and controlled by the pupils themselves under supervision was found to produce the best results, and the cities having the councils are very enthusiastic about the results which they have obtained.

RESULTS

The rapid growth of safety education in the school systems of the United States is apparent. Not one city included in this survey shows a total lack of interest in safety education, whether of a formal or informal nature. It is noticeable that where the percentage is low in either separate or combined courses of study in safety, the percentage is high for activities such as councils, safety patrols, and auto clubs.

A separate course of study is being used in 51 per cent of the cities. Although 38 per cent state that they have no separate course of study in safety instruction, they do include safety in their health education program. Therefore, it may be safely said that 89 per cent are interested in safety instruction.

It was further shown that safety education is favored when approximately one-half of the cities reported safety education compulsory either by state law or local regulation.

A person was assigned to supervise safety programs in 47 per cent of the cities. The title of the person in charge varied in some instances. In one he was known as the Safety Engineer; in another he was called the Director of Safety; one listed a Director of Physical Education and Safety; but the majority were listed as Directors of Health and Safety Education.

A definite time allotment for the study of safety was given in only 36 per cent of the cities. It is interesting to note that a majority of the 51 per cent reporting a definite course of study assigned definite time allotment in their curriculum for safety instruction.

A vast majority have organized safety patrols which are conducted in the elementary, junior high and senior high schools. The patrols are supervised for the most part by the school

departments and police departments; a few cities being assisted by private agencies. Simple insignias are used by the safety patrols in the majority of these.

It is also noticeable that many of the school departments of the cities which have a system of collecting and investigating school accidents also distribute to their teachers data of accidents occurring outside of schools.

The use of commercial safety material in the classrooms of the schools varies, the majority of the cities allowing its use but with restrictions.

Special instruction in crossing streets at intersections, playing in the streets, traffic and signal regulations, is given in most of the cities, with only a very small percentage feeling that this instruction is not necessary.

A little more than half of the cities concerned, it was found, cautioned their

primary school children at the end of each session, while the remainder relied on the police protection at dismissal time.

Safety councils, auto clubs, school patrols and other activities are carried on by many cities. In 35 per cent all three types of activities are encouraged. It is interesting to note that some that do not have safety patrols have safety councils or clubs.

The police have contributed their services to most of the cities' safety programs. Some have them part time, and others full time.

These facts on safety reveal that the school authorities of the country are mindful that the preservation of life is an obligation and duty which they must meet and discharge to the best of their ability. It has been shown through the returns by the 75 cities just how this obligation has been met.

Sioux Sanatorium Opened

THE Sioux Sanatorium was recently completed at Rapid City, S. C. This \$272,000 government institution for the Sioux Indians was formerly the site of an Indian school.

Arthur Joseph Wheeler, M.D., superintendent of the Albuquerque Indian Sanatorium of Albuquerque, has been appointed superintendent of the new sanatorium.

Registration and Approval of Public Health Laboratories as Carried on in Connecticut*

FRIEND LEE MICKLE, Sc.D., F.A.P.H.A.

Director of Laboratories, Connecticut State Department of Health, Hartford, Conn.

WITH so many public health activities resting upon the groundwork of laboratory findings there exists a need for official control over laboratories where daily are carried on examinations of body fluids and excretions, bacteriological or chemical analyses of milk, frozen desserts and milk products, or tests of water or sewage. Unfortunately, it is not difficult to call to mind public health laboratories where the quality of work carried on might be improved by the right kind of guidance. It may be profitable to review briefly some procedures and standards under which the quality of work in laboratories has been improved through supervision. Any suggestions presented will be offered with a full realization that conditions vary widely in different localities. It is a safe assumption that a set of procedures followed with some measure of success in one state could not possibly be successful in another without special adaptation to the new locale. The principles are applicable to all sections of the country.

Without general oversight from some official control agency there is no ques-

tion that results will at times come forth from public health laboratories that may not only cause real annoyance to individuals concerned but that may seriously interfere with progress in public health, mar the good work of the physician and the health officer, and surely exert an adverse effect upon the health of the citizen if not, in the extreme instance, cut short his life. Where is the public health official who has not experienced embarrassment in attempting to explain conflicting laboratory findings on similar specimens examined in different laboratories! It is illuminating that in Connecticut the annoyances and losses of money caused to the milk industry by the analyses and interpretations from unsupervised laboratories—private and public—became so serious two decades ago that the industry itself, independent of the state control agencies, sponsored the passage of legislation that since then has required approval of dairy laboratories and the licensing of all personnel.

There are several reasons for unreliable reports from laboratories. The shyster who deliberately falsifies his findings for the benefit of his client has seemed to be much more of a rarity, even in the state that has won the sobriquet of "the Nutmeg State," than

* Read before the Laboratory Section of the Massachusetts Public Health Association at the Annual Meeting, Boston, Mass., January 27, 1938.

might be expected. Far more frequently encountered is the well intentioned person with a partial lack of training and experience who considers himself capable of making, and reporting to the public, examinations for infectious agents in body fluids, tests on dairy products, analyses of water or sewage, or other laboratory determinations. Too often even the college graduate with very little training in bacteriology, chemistry, or public health, and sometimes with no real experience, will attempt to carry on laboratory work and make interpretations of findings that would not be attempted by the expert with years of practice to his credit. The failure to use proper apparatus and the improper use of even the best of equipment are frequent causes of unreliable results. Dependence upon obsolete technics and methods not generally accepted may lead to troublesome findings. Many of the causes of unreliable reports may be favorably influenced by supervision.

Early in this discussion it should be emphasized that official supervision is not *per se* a panacea for all the ills of unsatisfactory laboratories. To be effective a system of control must be carefully planned and efficiently carried on. By themselves, authority and inspection will never produce some dreamed-of utopia. The best trained laboratory expert, whether supervised or not, has to be constantly on guard against the many pitfalls that beset the laboratory worker who tries to do a perfect job. No one can do a perfect job all of the time. At times even the well trained laboratory worker may become careless. Usually the person who performs laboratory tests inaccurately or who makes misleading interpretations from his findings is a reasonably honest individual striving to the best of his ability to earn a living by putting to use what training he has been able to secure. All too often the

partially trained laboratory worker succumbs to the temptation to make tests for which his experience or educational background is inadequate. There still can be found poor laboratories in those states where approval is in force, and the well trained laboratory worker will occasionally make errors no matter how closely supervised. But these are the exceptions which emphasize the rule.

To bring about improvement under the conditions existing generally in public health laboratories, supervision must have as handmaidens education and coöperative effort. The supervising official who would be successful in improving quality of work must bring to his task interest in his work and a spirit of coöperation toward those with whom he works, and he must to a considerable extent be an educator and a tutor. Regardless of the authority he represents, he must be friend, fellow worker, teacher, and diplomat far more than he is inspector. Successfully to do these things he must be a trained and experienced public health laboratory man connected with some organization officially recognized for the enforcement of health legislation. It is not without reason that the state department of health has almost universally throughout the country been the repository for laboratory supervision. It is essential that in the approving of public health laboratories the state work in coöperation with the local health officer or local health department. The state health department has, or should have, an organization already perfected for dealing with local health interests. Neither in some other state control group nor in an organization national in scope can it be hoped to develop the flexibility necessary for adapting approval to local health conditions so easily or so well as it can be built up in the already functioning state health department.

With trained and experienced laboratory experts on its staff, with consultants always available on the epidemiological aspects and the water and milk and other problems, and particularly with a public health council or board already constituted for keeping regulations and rules within proper bounds, the health department appears to be the logically supervisory agency.

It is not that an officially designated body will be enabled to improve the quality of work in local laboratories by some magic show of policing authority. Rather will results be accomplished by restraint in the use of a potential power held in reserve for the very occasional instance where coercion is needed. The power to revoke approval that has been extended furnishes a handy correctional weapon and provides opportunity to make thorough investigation in the infrequent instance when it is necessary, but it is rather through educational effort and coöperation extended to local laboratories over long periods of time that in a manner not at all magical the quality of the work can be made to improve in both the good and the mediocre laboratory while the bad laboratory may solve its difficulties by passing out of existence. Through supervision, methods and procedures in widely separated laboratories may be unified, and research and incentive stimulated. Slow moving constructive effort will do what magic cannot accomplish.

GENERAL OR SPECIFIC APPROVAL

Laboratory approval may be a sort of blanket approval extended to a laboratory after inspection of the equipment and investigation of the qualifications of the personnel or the person in charge to cover any and all work that may be done. On the other hand, it is entirely feasible to limit approval to a specific list of tests and to insist that the results of no examination not

on the list be used or published until approval has been extended to cover that test. Blanket approval is beset with difficulties chiefly because the person in charge of a laboratory may be capable of making certain tests and yet be incapable of making or interpreting the results of some other determination. For example, many well trained chemists may not have the background of training to make and interpret properly rather simple bacteriological tests. Limited approval for specific lines of work is more generally in vogue and more to be recommended than is unqualified approval.

LAWS AND REGULATIONS

Prerequisites for official control of laboratory work, in whatever field, are law and regulation. A law may be either simple or involved. An example of the former is a statute requiring merely that any laboratory making specified examinations be either registered with or approved by the official control agency. A law requiring approval of every laboratory if it is to exist may work hardships upon an individual or a corporation, and a law providing alone for registration is not to be recommended; but when compulsory registration of all public health laboratories is combined with provision for approval of those laboratories meeting specified standards for high-grade work then registration becomes merely a sort of notice to the state and its citizens that a laboratory is being conducted at a stated location, while those laboratories meeting established standards enjoy the benefits that accompany official sanction. Under such legislative enactment no great amount of control is exerted over the registered laboratory—at least until the quality of work in a specific instance is so poor as to occasion serious complaint demanding investigation—but there is established a complete directory of laboratories

carrying on every phase of health work. Supervision is exercised only over the laboratory that has applied for and received approval. The public becomes educated to demand the services of the laboratory that can qualify under the law. Although the poor laboratory may become labelled as such by inference it is not legislated out of existence.

Under most circumstances it is desirable to have the law as simple and brief as is consistent with rather broad powers, and preferably to have it provide full authority for the approving agency to promulgate rules, requirements, and standards upon which approval shall be based. Power of revocation of approval for cause should be provided in the law, and the approving agency should be given full powers to make check tests or investigations desirable to determine at any time the accuracy of methods followed or the ability of the person in charge to report on or interpret any particular test. General provisions for enforcing the law in Connecticut are in the form of sanitary code regulations; departmental rules provide detailed procedures. With provisions made for enactment of a code and promulgation of regulations, the law itself may be concise yet comprehensive.

All types of public health laboratories should under the law be required to register, including those in city departments of health, in educational institutions, in hospitals, in milk plants, and those laboratories operated commercially or privately for profit. If registration of all laboratories is not required, the law may later be found to contain embarrassing loopholes. Experience has not revealed objection on the part of old established educational institutions and hospitals to register annually, and most apply for approval because usually there is no difficulty in meeting the requirements. This tends to strengthen and give broad scope to

the activity and helps to maintain high standards.

The limiting of approval to apply only to those tests where the results will be published or "used" for the purposes of diagnosis of communicable disease or release from quarantine or as the basis of an opinion of sanitary quality or one that involves the public health, has been found to have advantages. Under a law into which that provision is embodied a laboratory operated by a milk plant for the examination of samples of the firm's own product and of producers' supplies would be exempted from approval. Thus the law would not intrude into the private business of an individual or a firm. The laboratory technician at a milk plant might even become interested in testing the products of competitors and could legally do so under this type of law without applying for approval unless the results were published or some of them "used" by salesmen or in some other way such that the sales or interests of competitors might be affected or unless the products of the firm were advertised on the basis of the findings obtained. Should the results be used in such fashion it is evident the requirement of approval should apply. The situation is similar in respect to the water or sewage laboratory or regarding the physician who examines specimens in his own practice or the private sanitarium or institution making certain routine cultures or examinations of smeared preparations collected from patients remaining more or less permanently in the institution.

HOUSING AND QUARTERS

It is rather universally considered that adequate housing for the laboratory should be made a prerequisite for approval. Reasonably reliable examinations even of a bacteriological character can be carried on in fairly crude

quarters if the rooms are decently clean. For that reason standards for housing should not be set too high. Yet in this day and age it is certainly not going too far to require clean, comfortable, fairly commodious, and well lighted working quarters without involving undue expense. Regulations should be sufficiently flexible to allow the common sense and good judgment of the approving official a reasonably wide range of play. Requirements should be designed to encourage improvement in the housing of laboratories.

EQUIPMENT AND SUPPLIES

In a system for the control of laboratories provision should be made for requiring the use of standard equipment. It may be sufficient merely to require that apparatus be complete and in good order at all times as considered necessary for making each determination, examination, or analysis according to the method which the person in charge has agreed to follow. Such a requirement allows the control official enough leeway to meet special situations and yet gives him the necessary authority for insisting that standard supplies be used. Inspection should be provided to determine at reasonable intervals that the several kinds of apparatus in use are maintained adequate for any increasing volume or changing lines of work and that all equipment is kept clean and in good condition. It is surprising how far afield in using broken and worn-out equipment well trained laboratory technicians—and for that matter even directors of laboratories—will allow themselves to go where there is no supervision. Regardless of your or my opinion of the value of a particular laboratory test we would be agreed that the test had better be left undone than to be poorly or indifferently made because of poor equipment. Inspection

should be and can be so planned and carried out as to eliminate bad apparatus and promote the use of good standard equipment, supplies, and reagents.

METHODS AND PROCEDURES

The value of the work done in a laboratory usually is more a function of the method or procedures followed and of the accuracy and intelligence with which they are adhered to than it is a function of the housing and equipment. It is desirable there be definite agreement on the part of the person in charge of a laboratory before approval is extended that any test or analysis will be made strictly in accordance with specified methods. These may be the standard methods of the American Public Health Association, the Association of Official Agricultural Chemists, or another similar organization, or it may be preferable to specify they be the latest edition of the particular method approved by the supervising agency, which in turn can be made the standard method most widely recognized. Standard methods national or international in scope may not be altogether applicable to local situations or quickly amenable to changed conditions. It is a wise precaution to provide authority not only for demanding adherence to methods and procedures drafted by the regulating authority but also for setting up the machinery to modify them from time to time when the need arises.

LICENSING OF PERSONNEL

In some states the licensing of personnel is considered a sufficient safeguard against laboratory work of poor quality without any requirements affecting the laboratory itself; in other places, licensing of personnel is merely a prerequisite for approval of the laboratory; in still others, approval is extended without the actual issuance of licenses

to the personnel. It is sometimes customary to require the applicant for a license or a certificate of proficiency either to pass an examination or to submit credentials from an accredited institution of learning which certify that certain courses in bacteriology, chemistry, or public health have been completed with satisfactory passing grades. In one state a person passing an examination to do the simpler tests must later take a second, or even a third, test before receiving a license to make other more complicated determinations or to take charge of a laboratory. In Connecticut the person in charge of an approved laboratory must possess certain qualifications evidenced by investigation of credentials or by examination conducted by the approving authority. Full responsibility for the operation of the laboratory is then placed on his shoulders and the credentials of the other workers are not investigated. The qualifications of the heads of laboratories that are merely registered are not investigated since no responsibility is assumed by the registering authority for the quality of the work in those laboratories. This is because registration is considered merely as notice that laboratory tests are being made at that particular place without having the endorsement of the state department of health.

RESPONSIBILITY OF THE HEAD OF THE LABORATORY

When approval is extended to a laboratory, the writer believes that some person—ordinarily the one in charge—should be made strictly accountable for the accuracy of the work done and for the reliability of the interpretations issued from the laboratory. Experience has indicated that requiring the signature before a notary of the person concerned brings home the seriousness of the approval agreement in an effective way.

The person in whose name the laboratory is approved may be required to subscribe under oath to some such signed statement as the following one:

A. I agree that the conduct of the laboratory will be strictly in accordance with recognized standards of laboratory ethics and that no method or procedure will be followed that does not meet the approval of the certifying agency.

B. I agree that no examination aside from those listed on my application blank, will be made without notice being given promptly in writing to the approving agency that such an examination has been made. I also agree that as the person in charge I will upon request furnish the approving agency with a complete description of any method or procedure followed in making any specified determination for which approval is extended.

C. I agree to be responsible for the accuracy and reliability of the findings made by any person or persons employed in the laboratory, and for any interpretation based upon those findings.

D. I agree that if at any time I am engaged on a part-time basis I will inform the approving agency of the approximate amount of time given to this position.

E. I agree that in the event I sever my connection with the laboratory, or am about to sever it, I will immediately notify the approving agency in writing and return the certificate of approval; and also that I will notify the approving agency in writing prior to taking extended leave-of-absence.

F. I agree to return, on December 31 of each year, the certificate of approval issued for the expired year.

COSTS AND FEES

The question may be asked: Do the benefits from registration and approval justify the costs involved? Similar questions were doubtless asked when licensing of physicians was an issue before the public and when other licensing and supervisory measures were first proposed. Upon the extent of the need for it should the decision to undertake the project rest, rather than upon the costs that will be entailed. Aside from salaries for clerical work and the cost of certificates and printing, the chief expense will be for time and travel of the inspector or supervisor. He should

be a trained and experienced public health laboratory expert and should have an adequate salary. A well trained man can visit several laboratories in one day if they are not too widely separated and do a thorough job of inspecting. If the health department is the approving agency, a person already a member of the laboratory staff may be assigned to this work on a part-time basis and thus approval be combined with a sort of liaison service between the department and the local health officers and the staffs of local hospitals and institutions in a way that both lessens the cost of supervision and further justifies the expense. Fees may be charged for registration to cover in part the inspection costs, but this has not been done in Connecticut. At least one state provides state aid to approved laboratories but need has not been felt for that in Connecticut.

THE VALUE OF AN APPROVAL SYSTEM

At times there are issued from public health laboratories reports of findings that are inaccurate, and interpretations of laboratory tests ranging from conclusions merely misleading to opinions which may upon occasion adversely affect the health of the public, shorten the lives of citizens, or ruin the reputations of milk producers or other individuals. Erroneous or fallacious laboratory reports and conclusions tend to lower the confidence of the public in the work of laboratory testing in general. Very occasionally unreliable reports are the outcome of dishonest attempts to mislead. Far more often they result from careless or thoughtless errors on the part of well meaning persons improperly qualified and experienced to make and interpret particular tests. Perhaps even as frequently mistakes occur because the analyst has failed to follow an improved and up-to-the-minute procedure that should have been readily available to him or because he

has used poor equipment, supplies, or reagents that have rendered the findings unreliable. Once in a while an experienced person in charge of a busy laboratory may base an interpretation upon unreliable findings or upon tests made by an unqualified or careless person.

If the person in charge of a laboratory is legally required to obtain a certificate of approval before reporting any test where the results will be used or published, this step will go far toward improving the quality of the work providing a well organized system of approval and inspection gives opportunity year after year for education and coöperative effort to function along with the regulatory aspects of approval. If the laboratory director has agreed under oath to surround the work with a variety of safeguards, is he not more likely to supervise each analysis carefully and to weigh well the conclusions based upon the laboratory findings? Requirements for adequate housing and standard equipment, apparatus, and reagents are desirable, but even more important is provision for determining the qualifications of the person in charge—either by examination or through investigation of credentials—before approval is extended. It is likewise important that the person in whose name approval is granted be required to sign an agreement with the certifying agency that specified standards for high grade work will be consistently maintained and that acceptable methods and procedures will be followed.

Experience in Connecticut indicates that under a system of approval laboratories issue fewer conflicting reports than formerly and that there are less complaints from physicians and patients and not so many objections from persons whose products are under test. Improvement of methods can be secured by a process of selection of the best technics without deadly standardi-

zation taking place. Under a system of approval, which need not be unduly expensive, there is added incentive for persons owning and operating laboratories to man them with qualified personnel and increased opportunities for technicians to demand proper equipment and supplies with which to work. This is bound to lead to service of better quality. Research activities can be stimulated toward discovery of new methods. In several instances a statewide association of laboratory directors and technicians has been the outgrowth of a system of approval—evidence that benefits arise from the system.

With a carefully planned system of laboratory approval in operation it should seldom be necessary for the vested authority to be exercised, but the machinery is set up for preventing the bungler or the novice from issuing laboratory reports, for supervising the shyster laboratory, and for improving the quality of work in the laboratory where the training or experience of the

personnel is barely adequate for carrying on the variety of tests for which approval has been extended. With compulsory registration of all public health laboratories with the state health department and provision for approval of those that meet specified requirements, the state or commonwealth need not interfere in the business, or with the livelihood, of any of its citizens; yet this important public health service will be placed on a higher plane to the benefit of many persons. By means of educational efforts and well directed publicity the public can be taught to expect differences in the service rendered by the approved laboratory from that to be expected from the one which is only registered. It would seem that no laboratory should be the worse for being under a properly conducted system of registration and approval, and certainly the poor laboratory should be improved or show cause to the public why it should continue to prosper or even to exist.

Development of International Coöperation Among the Health Authorities of the American Republics

HUGH S. CUMMING, M.D., F.A.P.H.A.

Surgeon General (Ret.), U. S. Public Health Service; Director of the Pan American Sanitary Bureau, Washington, D. C.

INTERNATIONAL Sanitary relations leading to coöperative effort among the health authorities of the American Republics have followed a harmonious and evolutionary course over a period of half a century; that is, since the general health conference which met in Washington in 1881, at which both European and American countries were represented.

At the First and Second International Conferences of American States, held respectively in Washington in 1889, and in Mexico City in 1901-1902, international public health was a leading subject in the agenda. The latter of these conferences recommended that—

A general convention of representatives of the health organizations of the different American Republics shall be called by the governing board of the International Union of American Republics to meet at Washington, D. C., within one year from the date of the adoption of these resolutions . . . that said convention shall provide for the holding of subsequent sanitary conventions . . . that it shall designate a permanent executive board . . . to be known as the International Sanitary Bureau with permanent headquarters at Washington, D. C.

These brief quotations set forth the historical background involved in the

creation of the Pan American Sanitary Bureau and the Pan American Sanitary Conferences, 9 of which have been held to date, the 10th being scheduled to meet in Bogotá, Colombia, in September of this year. Previous conferences of this series have been held in Washington in 1902 and 1905; Mexico, 1907; San José, 1909-1910; Santiago, Chile, 1911; Montevideo, 1920; Habana, 1924; Lima, 1927, and Buenos Aires, 1934.

In addition, between the dates of the meetings of the sanitary conferences, the Directing Heads of the National Departments of Health of the American Republics have lately been called to meet in Washington to discuss administrative and other public health problems of mutual interest, at intervals of 5 years. Three of these latter meetings have been realized: in 1926, 1931, and 1936.

Sanitary Conventions or Treaties—
The Second International Sanitary Conference, held in Washington in 1905, concluded *ad referendum* the Sanitary Convention of Washington, which was ratified by Costa Rica, Cuba, Chile, Ecuador, United States of America, Guatemala, Mexico, Nicaragua, Peru, and Venezuela; and adhered to by

Brazil, Colombia, El Salvador, and Honduras. This first treaty of international American public health became therefore applicable in 14 of the 21 American Republics.

At the Seventh Pan American Sanitary Conference held in Habana in 1924, the Sanitary Convention of Washington was amended, rewritten, and renamed the Pan American Sanitary Code, and has been ratified by all the American Republics. It bears the distinction of being the first Pan American treaty to be accorded this unanimous approval.

The Pan American Sanitary Bureau—Although the organization of the International Sanitary Bureau was effected by the First International Sanitary Convention in 1902, this body did not take actual form as an autonomous entity until the year 1922, following its reorganization by the Sixth Pan American Sanitary Conference of Montevideo, Uruguay, in 1920, and coincident with the beginning of the publication of the *Bulletin of the Pan American Sanitary Bureau*. Its further development and recognition were materially aided by the adoption of the Pan American Sanitary Code, which more clearly defined its functions and duties.

As at present constituted, the Pan American Sanitary Bureau consists of an honorary director, a director, a vice-director, a secretary, 4 members, and the provisional president of the forthcoming Pan American Sanitary Conference, all elected by the Ninth Pan American Sanitary Conference at Buenos Aires (1934) and constituting the Directing Council. All sections of the Americas are thereby represented. Under the terms of the Pan American Sanitary Code, a fund of not less than \$50,000 is contributed annually by the 21 American Republics to carry on its activities.

Traveling Representatives—As an

effective and practical means of attaining its aims of coordinating the health activities of the Republics of the Americas, the Sanitary Bureau has appointed from time to time traveling representatives. Their mission is to cooperate with the national health authorities of the various Republics. Since 1927, 12 such representatives have been named, 4 being on duty at the present time. In addition, 3 sanitary engineers, engaged in mosquito studies and surveys of public water supplies and sewage disposal systems are similarly employed.

Of signal interest in the international public health field has been the work of these representatives especially in the antiplague campaigns in the Republics of Ecuador and Peru, since 1929 and 1930, respectively. Active measures have been carried out for trapping and poisoning of rats, flea surveys, study of the epidemiology of active foci of disease, and especially aiding in the prompt reporting of human cases and deaths from plague, and of rodent infection, to the Pan American Sanitary Bureau and through this agency to the health authorities of the American Republics and to the International Office of Public Health with which the Sanitary Bureau cooperates.

Another disease of international import, viz., yellow fever, has received considerable attention. Traveling representatives have been detailed to cooperate in the studies of the Rockefeller Foundation, and special measures have been adopted to vaccinate against yellow fever the crews of airships in international traffic and to promote vaccination of flight personnel of national airways in each country. Under a cooperative plan devised by the Pan American Sanitary Bureau, certificates of origin are provided for air travelers in international traffic when deemed expedient, in an endeavor to have a record of their whereabouts dur-

ing the 6 days prior to departure from yellow fever endemic areas.

Reporting of disease—To be of any value, the reporting of dangerous communicable diseases must be prompt and complete. By cable, by airmail, and by ordinary correspondence, the Sanitary Bureau constantly receives reports of diseases from the American Republics. These data are compiled and immediately released in the form of a *weekly report* mailed to all the sanitary authorities of the Pan American countries and to interested international health organizations. Whenever urgent, the information is cabled or sent by air mail.

Publications—In line with the purposes for which it was created, the bureau has endeavored to broaden its scope by a far reaching program of education in preventive medicine and sanitary science, especially adapted to the needs of the health officer, the practising physician, the sanitary engineer, the visiting nurse, and other health workers. Consequently, it has been the policy of the bureau to have its monthly *Bulletin*, with a present issue of approximately 9,000 copies, distributed as widely as possible. The *Bulletin* is thus received by physicians and health authorities and others concerned, in almost every town of 2,000 inhabitants or over throughout the Latin American Republics. Although the material is mostly in Spanish, articles are also carried in French and Portuguese and occasionally in English. If there is no local physician in a small village, attempt is made to reach a pharmacist, nurse, teacher, midwife, or some other person in the locality who may be interested in the prevention of disease and in the conservation of the health and well-being of the people.

Coöperation with international health agencies—The bureau follows closely the work of the International Health Division of the Rockefeller Foundation in matters involving health prob-

lems in the Americas. Moreover, the Constitution and By-Laws provide that "The Pan American Sanitary Bureau shall coöperate with the International Office of Public Health of Paris, and also with other international bodies such as the Health Section of the League of Nations."

Through an exchange of correspondence, and under the provisions of Article 7 of the International Sanitary Convention (Paris, 1926), the Pan American Sanitary Bureau acts as the Regional Agency of the International Office of Public Health of Paris in the collection and transmission of information relating to health and sanitary conditions in the American Republics. By virtue of this arrangement, the Pan American Sanitary Bureau transmits to the Paris Office reports of communicable diseases occurring in the republics of the Western Hemisphere, and in turn relays to them the reports received from that Office relating to such diseases in other parts of the world. This arrangement avoids duplication of effort and provides a satisfactory basis of coöperation and understanding in international health relations between the Eastern and Western Hemispheres.

Miscellaneous activities—The Pan American Sanitary Bureau follows very closely all international medical relations in which the American Republics are concerned, usually being represented at important health congresses of whatever nature. No opportunity is overlooked to bring about better understanding among scientific health workers, especially those of the medical and engineering professions.

Following the recommendation of several conferences in the past, the bureau undertook the translation of the latest edition of the *Pharmacopœia of the United States* into Spanish, in order that it may be made available in those countries where this language is spoken. This was undertaken in coöperation

with the Board of Trustees of the United States Pharmacopoeial Convention, its main purpose being to secure better and more nearly uniform standards of strength and purity for the drugs used in the treatment and prevention of disease, and also to serve as a ready reference to those countries in the preparation of their own national pharmacopoeias.

Another of the important activities of the bureau is its mission as a consulting agency. Inquiries are constantly received from health officers and others involving problems of public health administration, treatment, research, statistics, and many other features.

The bureau also compiles and publishes vital statistics of the American Republics.

CONCLUSION

This brief survey of the Pan American Sanitary Conferences and the Pan

American Sanitary Bureau sets forth their historical background and their development over a period of half a century, though most of the activities of the bureau have been developed within the last decade. In a harmonious and coöperative spirit, it has been possible to attain the elimination of drastic quarantines, to secure the prompt reporting of quarantinable diseases, to aid in obtaining increased appropriations for public health work, and to demonstrate the usefulness of the Pan American Sanitary Conferences and their executive organ, the Pan American Sanitary Bureau, in the ever increasing field of international coöperative measures in the interest of all the people of the various republics concerned.

NOTE: This paper was presented before Le Comité Permanent d l'office International d'Hygiène publique, May, 1938.

Positions and Rates of Pay in Public Health Agencies*

ANTHONY J. BOROWSKI, DR.P.H.

*Research Analyst, National Health Inventory, U. S. Public Health
Service, Washington, D. C.*

THE positions of 19,000 persons as reported by health agencies with an annual pay roll of some \$23,000,000 should, on analysis, be of interest to the public health administrator and to the employee. Distribution of various types of employees within a given budget reflects the nature and extent of a program since approximately 75 per cent of the expenditures among health agencies covered by this study were consumed by salaries paid to staff members. Indexes, such as average salaries, may be of assistance to the administrator in allocation of funds necessary to supply the personnel required for contemplated health activities. Average salaries received by groups of employees with varied training and technical qualifications offer to the prospective public health worker some information in regard to opportunity for remuneration in this rapidly developing field of public service.

Information about employed personnel which forms the basis for this study was submitted among other data by some 2,500 agencies in health jurisdictions confined to areas within county limits. These agencies functioned in 94 counties of 19 states scattered throughout various sections of the

country. The total inhabitants numbered approximately 34,000,000. As may be noted in Table III, the sample is heavily weighted with populous counties and with those having a high percentage of urban inhabitants; within this sphere, however, it presents a satisfactory cross-section of the social, economic, and industrial development of the United States. Data received from the 2,500 classified public health agencies were not in every case suitable for analysis, inasmuch as some 650 organizations rendered public health service in a limited fashion or to such a small degree that returns would have little meaning for this study. The majority of these were primarily interested in phases of activity other than that of rendering direct public health service. This group may be dismissed with the statement that they were not operating agencies in the public health field, although they bore such classification in local directories. The detailed discussion will, therefore, deal with data submitted by 1,861 agencies having some tangible organization and program.

Of the 1,861 agencies studied, approximately 75 per cent were under governmental control, and are referred to as official agencies. This percentage includes a large number of lone health officers; the great majority of whom devoted only a part of their time to

* From the Division of Public Health Methods, National Institute of Health. Study conducted in connection with the National Health Inventory.

* Total population 33,978,479

health duties. The other agencies were non-governmental and carry the designation of nonofficial or voluntary. Table I presents the distribution of all full- and part-time individuals according to type of health agency. Briefly, official agencies engaged on the average 6.5 full-time and 2.7 part-time persons, as compared with 7.4 full-time and 5.7 part-time persons employed by the nonofficial group. If health departments alone are considered the number per department was considerably higher, being approximately 27.1 full-time and 7.1 part-time persons. The total number of people em-

ployed by all health agencies per 100,000 inhabitants was 55.7. The rate for full-time and part-time employees was 37.0 and 18.7 respectively. Approximately three-fourths of the full-time and three-fifths of the part-time workers were employed by the group of official agencies.

Nurses constituted the largest single group of full-time employees in both the official and nonofficial group (Table II). In relation to personnel of other classes the proportion of nurses was much higher, however, for the non-official agencies than for the official. The 295 health departments reporting

in this study employed 2,921 full-time and 143 part-time nurses, or an average of 9 nurses in all for each 100,000 population. Nonofficial agencies employed an average of 6.6 nurses for a similar population unit. The agencies combined reported 5,795 full-time and 481 part-time nurses, or an average of 18.5 per 100,000. Second in order of magnitude was the group designated "all others." This term is rather inclusive but for practical purposes it may be taken to mean clerical personnel. True, engineers, bacteriologists, chemists, and statisticians are included but they were not numerous in proportion to the total. The third largest class of people employed was that of inspectors. Such workers, as a rule, were not found in voluntary agencies since they are usually engaged on activities which require the application of sanitary laws that only representatives of government are empowered to enforce. Thus, as expressed by pay roll structure, sanitation—an activity of official agencies for many years—even today is playing an important rôle in the program of health departments.

Medically trained persons made up the group ranking next in number; 782, or 8 per cent of all full-time persons in official health agencies, were physicians. Of these, two-thirds were staff members, while the others were employed exclusively in clinics. On the other hand, but 87, or less than 3 per cent

of the full-time personnel listed by the nonofficial group, were reported to have had medical training. The relatively small number of full-time physicians rendering public health service was offset somewhat by the large number of physicians serving on a part-time basis. In the official group of agencies 2,213 employees, or 57 per cent of the part-time personnel, were medically trained; for the nonofficial group 1,129, or 45 per cent, were of this class.

Only 136 full-time employees in both the official and nonofficial agencies were dentists, but it is well to note that oral hygiene programs as a rule are sustained in a large measure by part-time dentists and by dental hygienists who do not hold a regular degree in dentistry.

Because of the nature and content of programs, employees of a particular class may be expected to predominate in the staff of certain organizations. Nursing agencies, for example, employed a greater number of nurses in proportion to the total personnel than did other organizations. The agencies classed as "other official," mostly schools, showed a high ratio of staff physicians to all personnel employed. The nonofficial group of agencies with maternal and child hygiene as their chief interests employed proportionately more clinic physicians than did any other type of agency. Organizations concerned primarily with tuberculosis engaged a high proportion of employees

TABLE III

Employment Rate of Different Types of Full-time Personnel in Health Agencies of 94 Counties According to Population of the County

Full-time Personnel per 100,000 Population						
Total	Physicians		Nurses	Dentists	Inspectors	All Others
	Staff	Clinic				
37.0	1.6	0.9	17.1	0.4	3.4	13.6
17.8	1.0	0.0	11.1	0.0	1.0	4.7
14.1	1.2	0.0	8.4	*	1.0	5.5
18.6	1.5	0.3	8.8	0.1	2.2	5.7
32.2	1.7	0.3	15.3	0.3	3.1	11.5
40.1	1.8	1.2	13.2	0.5	3.7	14.9

in the unspecified class designated as "all other."

For comparative purposes, staffs were also considered in terms of the number of employees per 100,000 inhabitants in counties of different population groups. Table III presents such rates. All of the health agencies studied, when combined, employed 37 full-time persons per 100,000 population. The group of counties with 500,000 or more inhabitants revealed the highest rate, which was 40.1. It may be readily observed that, in general, the rate for each class of employee increased as the counties were found in higher population classes. Counties with less than 20,000 inhabitants showed deviation from this array in two instances. Nurses and the class designated "all others," showed a higher rate per 100,000 than that found in the group of counties next in order of size.

As noted previously, relatively few dentists and clinic physicians serve on a full-time basis. A striking point is the rapid increase in rate of employment for persons designated "all others" as counties occupy larger population groups. In some degree this increase represents additions to the technical staff of engineers, laboratory workers, statisticians, and persons with related training, but a much larger proportion is due to the greater number of clerks and helpers of various types.

The average annual salary of whole-time staff physicians was higher in health departments than in either the

other official or the nonofficial group of agencies. This is made evident in Table IV. Nonofficial agencies paid the medical group an average salary of \$2,911, as compared with \$3,014 in health departments and \$2,141 in the other official group. Clinic physicians received a much smaller salary, the sum being lower than one might expect. The average salary of this group as reported by all agencies was \$1,636. This does not appear comparable with salaries paid to other employees of similar or lower grades.

The average remuneration for nurses in the several types of agencies was about \$1,500. This uniformity is perhaps due to two factors: (1) the large number of nurses reported; and (2) the basic similarity in their training and duties. The divergence in salaries paid to dentists by official and nonofficial agencies was as great as that found in the case of clinic physicians. However, nonofficial groups paid dentists lower salaries than did governmental agencies, whereas their practice was reversed with respect to payment of clinic physicians. Inspectors were paid an average salary of approximately \$1,900 by health departments, but this figure cannot be contrasted with those of other agencies since so few employed inspectors. The remaining miscellaneous group of health department employees averaged in salary \$1,545 per person or approximately \$250 more per year than the amount received by the nonofficial miscellaneous group.

TABLE IV

Number of Full-time Employees in Health Agencies of 94 Counties and the Average Salary Paid to Specified Types of Personnel by Agencies of Each Class

Type of Personnel	All Agencies		Health Departments		Other Official		Nonofficial	
	Number of Employees	Average Salary	Number of Employees	Average Salary	Number of Employees	Average Salary	Number of Employees	Average Salary
Staff physicians	557	\$2,881	442	\$3,014	81	\$2,141	34	\$2,911
Clinic physicians	312	1,636	160	1,415	99	1,659	53	2,263
Nurses	5,795	1,484	2,921	1,463	842	1,503	2,032	1,507
Dentists	136	1,961	76	2,151	16	2,171	44	1,556
Inspectors	1,162	1,915	1,157	1,915	2	1,890	3	1,876
All others	4,612	1,472	3,240	1,545	247	1,315	1,125	1,297

As a supplement to the data on full-time employees and their respective average salaries found in Table IV, some mention should be made of the 780 lone health officers. Of the 732 who served on a part-time basis, 452 reported data on money received; the others either received no compensation or failed to record satisfactory information on this question. Only 10 of the 452 received more than \$1,000. The average for all was \$197 per year, while the highest paid received \$2,400. Among the 47 full-time lone health officers, the lowest salary was \$300, the highest \$4,000, and the average \$1,470.

Of the 1,861 health agency administrators, including the lone health officers, 21 per cent failed to record salaries and 12 per cent received none. Most of those who gave no information regarding their salaries were in charge of official agencies. Among the group reporting on salary no full-time administrator of an official agency worked gratuitously, but there were 8 with nonofficial organizations who served without pay. In 95 official and 104 nonofficial agencies part-time administrators received no remuneration.

ployment. The median salary and interquartile salary range for directors of each classification are also shown. The largest number of full-time executives in the official groups were physicians with a salary range of \$3,205 to \$5,683 paid to the middle 50 per cent. The remuneration of those serving as full-time heads agrees very closely with the observation made by Leven.¹ According to his report in the findings of the Committee on the Costs of Medical Care, the median remuneration of all salaried physicians in the United States was \$4,213. The median salary for 107 full-time heads in the official group of this study was \$4,214, and in the nonofficial group the figure for 17 full-time heads was \$4,500.

Fifty per cent of the full-time administrators in the nonofficial group were nurses, with a median salary of \$2,015. This was approximately \$550 more than that paid to nurses serving as administrators in the official group. Lay persons served as full-time heads in 124 agencies. In official agencies the median salary of the full-time group was \$1,632 and in the nonofficial group of agencies, approximately \$1,906.

TABLE V

Median Salary and Interquartile Salary Range for Full- and Part-time Administrative Heads of Official and Nonofficial Health Agencies in 94 Counties According to the Professional Training of Administrators

Administrative Heads of Official and Nonofficial Agencies	Number of Administrative Heads		Salary Paid to Each Type of Administrator			
	Full-time	Part-time	Median		Range of the Middle 50 Per cent

Nonofficial						
Physicians	17	19	4,500	1,550	3,524- 6,438	488- 4,083
Registered nurses	103	12	2,015	750	1,505- 2,831	350- 1,250
Other professional persons	30	6	2,250	1,050	1,650- 3,525	775- 2,500
Laymen	55	6	1,906	1,000	1,172- 2,891	925- 1,013

In Table V are presented, on the basis of professional training, the reporting group of 1,254 administrators, classified as to full- or part-time em-

Those administrators with training classed as "other professional" constituted the minority in both groups of agencies; however, it is noticeable that

the median salary of such heads was higher in the official than in the non-official group. Full-time heads with other professional training received a median salary of about \$3,410 in official agencies as compared with about \$2,250 in the nonofficial.

Over 90 per cent of the part-time administrators of official agencies were either physicians or lay persons. In contrasting the two, the salary range of the middle 50 per cent for physicians was distinctly higher than that for the laymen, since 25 per cent of the latter received less than \$31 per year for their services. Although only 43 non-official agencies were directed by part-time heads, the analysis did not show the same predominance of physicians and lay persons.

In summary, it may be said that herein are presented data pertaining to opportunities for employment in 1,861 local public health agencies, including both official and nonofficial organizations. With few exceptions, this is a complete coverage of remunerative positions in 94 counties. From these data one cannot draw conclusions regarding the nation as a whole since the study counties represent the more populous areas where organization for public health is above the average. This analysis reveals, however, that more than one-third of all agencies studied consisted simply of lone health officers, nearly all of whom served on a part-time basis. Furthermore, in the agencies which engaged more than one person, one-third of the employees also

served on a part-time basis. A higher percentage of personnel employed by nonofficial agencies than by official were classified as part-time employees.

Nearly one-half of the 12,574 full-time personnel employed by the 1,861 health agencies under discussion were nurses. Employees designated "all others" ranked next to nurses in number. This category is composed chiefly of clerical personnel, although a relatively small number of engineers, bacteriologists, chemists, and statisticians are also included. In both official and nonofficial agencies physicians and dentists were more frequently employed for part-time service than for full-time.

The average salary paid to full-time personnel by all classes of health agencies was as follows for the various types of employees: staff physicians, \$2,881; clinic physicians, \$1,636; dentists, \$1,961; inspectors, \$1,915; nurses, \$1,484; and all others, \$1,472. Salaries varied according to the administration of the agency. Some part-time administrators donated their services; this practice was more frequently followed in nonofficial agencies than in official. Physicians received higher salaries than administrators of any other type in both nonofficial and governmental agencies. In general, both full- and part-time administrators drew higher salaries in nonofficial agencies than in official.

Trichinelliasis in San Francisco*

M. HOBMAIER, M.D., AND J. C. GEIGER, M.D., F.A.P.H.A.

*George Williams Hooper Foundation for Medical Research; and
Department of Public Health, San Francisco, Calif.*

SINCE the perfection of newer methods of diagnosis, trichinelliasis in the United States has attracted wide attention. It has been stated that from 5 to 30 per cent of the population has been found to carry trichinellae. The public health officer must consider these figures with some degree of skepticism. Serologic and digestion methods enable the investigator today to detect not only clinical trichinelliasis, but also the so-called zoölogical trichinelliasis. The latter comprises about 75 per cent of all cases, a few trichinellae being found, which may be quite insignificant from the standpoint of public health. The figures in all likelihood are the result of more perfected methods, and not those of an increase in actual clinical infections. Furthermore, results are available as to infections in cadavers, and this method of investigation necessarily cannot discriminate between infections of several years' standing, but must include all infections which may have occurred, perhaps without symptomatology.

What health officers need is that a diagnosis be made during the onset of the disease and the case promptly reported, so that the source may be found and further infections prevented. The figures obtained by such methods would be considerably lower, and

would probably not differ greatly from those of early investigators.

The responsibility of avoiding trichinelliasis is placed by the regulations of the meat inspection laws to a great extent on the consumer. Cases continue to occur in San Francisco, showing that the existing policy is not without danger. Difficulties may arise through violations of the existing laws by producers and lack of care on the part of consumers.

In civilized countries, trichinelliasis in man is connected with the consumption of pork food products carrying viable parasites. Other sources, such as bear, wild hog, badger, dog-meat, can usually be avoided. Some countries have tried to prevent infections in man by examination of every hog slaughtered. In the United States, this has been tested, but abandoned as impracticable. If trichinelliasis in pigs could be prevented, there would seemingly be no trichinelliasis in man. How market hogs become infested and how this may be prevented has interested the San Francisco Department of Public Health since 1934. This paper deals partly with such efforts and the conclusions resulting from the investigations.

Many of these conclusions have been admirably expressed by Hall.¹ The senior author, Hobmaier, had reached identical conclusions in July, 1936.

* Summary of Investigations 1934-1935.

Likewise, McNaught and Anderson² have reported on their investigations in San Francisco.

From 1927 to 1937, inclusive, there have been reported 212 cases of trichinelliasis in San Francisco, with 6 deaths. The largest number reported was in 1930, 54 cases, and 1 death; and in 1937, 9 cases and 1 death, the latter being the smallest number since 1927. In an analysis of the alleged causative food products, 51 were due to pork roasts and chops, 40 to pork sausages, mainly of the variety served at cocktail parties, 42 to salami, 9 to pickled pork, 9 to mettwurst, and 1 to bear meat. There has not been a case traced to salami manufactured commercially in San Francisco since the promulgation of stringent regulations by the Department of Public Health in 1934.

Only 16 specimens of the suspected pork or pork products were obtained for laboratory examination, and only 4 were proved positive. This shows how difficult it is to obtain the suspected food for investigation. When pork or pork products are blamed for cases or outbreaks, it is rare, despite efficient health organization, to secure evidence other than epidemiologic. Of the human cases, the laboratory diagnosis was made from muscle tissue on autopsy in 6, by skin test in 8, and by eosinophilia in 88.

The trichinella is a parasite of a great variety of hosts, among which, and of especial interest here, are those living in close relationship to man; namely, the pig, rat, cat, and dog. The rat only has preserved the natural cycle of propagation of trichinella from rat to rat without obligatory introduction of the parasite from outside. The main outside sources for infections in rats are pork and pork food products, the remote source being infected cats or dogs. In man, the trichinella has no means of propagating, and in the cat

or dog it occurs rarely. Trichinellae in man, cat, and dog, therefore, are dead ends in the life cycle. It is possible for rats to feed on carcasses of cats and dogs killed on highways by automobiles. The valuable assistance given by the Humane Society for Prevention of Cruelty to Animals of San Francisco in eradication of trichinelliasis by the safe destruction of thousands of dogs and cats each year deserves special mention.

The natural cycle of trichinelliasis from pig to pig has been ordinarily interrupted, because pigs are unlikely to feed on carcasses of other pigs. The possibility of transfer of trichinellae in pigs by feeding on infected feces seems to be quite remote, and placental infections apparently do not occur.³ The original cycle, however, may be re-established where infected pork and pork products are fed to pigs. It is possible that where this condition exists the feeding on infected rats is a secondary source, and still more remote is the possibility of infections by feeding on carcasses of infected cats or dogs. Moreover, on premises where infected pork or pork products are fed to hogs, the rats are likely to show a high incidence of trichinellae.

In 1935, there were examined for trichinellae 2,000 rats trapped in San Francisco: *Rattus alexandrinus*, 147, with 1 rat infected; *Mus rattus*, 237, 3 infections; and *Mus norvegicus*, 1,616, 125 infections. The distribution of the trichinella cases among the rats is shown in Table I.

TABLE I

Weight Grams	Rats Investigated	Infected Specimens	Percentage of Infections
Up to 50	104	0	0
100	438	3	0.7
150	206	2	1.0
200	159	8	5.0
250	142	11	7.7
300	129	19	14.7
350	155	22	14.2
400	125	24	19.2
450	91	15	16.5
500 and more	67	21	31.3

The figures in the table were obtained by microscopic examination of the diaphragms of the rats. Of the 129 infected rats 57 were males and 72 females.

The percentage of infections was 6.4. Young rats weighing 150 gm. or less showed 0.7 per cent of infections; middle-aged rats weighing up to 250 gm., 6.3 per cent; full-grown rats weighing over 250 gm., 17.8 per cent. The number and severity of infections increased with weight and age, and may be the result of continued exposure to new infections. In 6 specimens, there were found encysted and blood trichinellae; in 4, young trichinellae and those showing beginning calcification; and in 8, intestinal trichinellosis combined with muscular trichinellosis. Among 5 rats partially consumed in traps, one showed encysted trichinellae.

The infected rats were trapped as follows:

Markets	44	Dwellings	6
Abattoirs	36	Apartment	
Stables	11	houses	6
Groceries	3	Vacant lots	7
Warehouse	1	Miscellaneous	
Restaurant	1	places of un-	
Hotels	2	known nature	8

Many other places were investigated, but the rats were found free from infection. The disease seems to be restricted to certain foci where infected food is available. Trichinellae infected rats living in city limits are, of course, no direct menace to public health, provided there are no hog ranches, or that hogs are not maintained in abattoirs for a considerable time. They are a valuable indicator that trichinellae infected pork or pork products are improperly handled, whereby the rat infested premises may become foci of infections. There is no doubt that improper storage of food and carelessness in garbage disposal are sources of rat infestation.

Another focus of infection is repre-

TABLE II

Examination of Rats Trapped on Hog Farms

Hog Ranch	Rats Investigated	Infected Rats	Percentage of Infections
1	170	55	32.3
2	46	15	32.6
3	30	6	20.
4	158	54	34.1
5	62	12	19.3
6	189	52	27.5
7	105	36	34.3
8	17	5	29.4
9	34	8	23.5
10	20	2	10.
11	12	3	25.
12	6	2	33.3
13	24	3	12.5
14	6	1	16.6
15	7	2	28.5
16	6	1	16.6

sented in uncontrolled garbage dumps. Infections may result not only from unsafe human food contained in the garbage and from predatory habits of rats, but also from infected rats trapped in city limits and thrown into the garbage can. Among 161 rats investigated from one of these sources outside of San Francisco, 11.8 per cent were found infected. This is another illustration that garbage disposal of cities has to be carefully supervised.

The results of the examination of rats trapped on hog ranches which feed garbage is of interest as shown in Table II.

These data show 257 (or 28.8 per cent) infected out of 892 rats examined. Trichinellosis is to be expected in hogs on these ranches. Some information has already accumulated in this regard.

Garbage feeding causes trichinellosis only in so far as it contains raw or undercooked pork. Infections may be few or even absent when garbage from establishments where great economy is exercised in utilizing food-stuffs is fed. Severe infections may be expected where meat scraps are abundant, as in the garbage of meat markets.

Ten groups, 201 hogs, from 6 to 12 months old, have been investigated.

Fifteen to 20 gm. of muscle tissue of the pillar of the diaphragm have been treated by the digestion-filter, or by a modification of this method. No dead trichinellae have been found.

RESULTS OF EXAMINATION

1. Two pigs raised on garbage dump land. Both pigs infected, one showing 11.1; one, 0.8 trichinellae per gm. of diaphragm.

2. Twenty-nine pigs from a hog ranch near San Francisco feeding garbage from hotels and restaurants of San Francisco, and from three hospitals. Three pigs slightly infected; number of trichinellae 0.5, 0.7, and 1.3 per gm. respectively.

3. Thirty-five pigs from a hog ranch in San Francisco, feeding garbage from hotels, restaurants and from one hospital of San Francisco. Mild infections in 4 pigs: 0.2, 0.4, 0.9, and 1.6 trichinellae per gm.

4. Sixteen pigs from a hog ranch in San Francisco. Source of food, garbage from hotels and restaurants. Two mild cases of infections: 1.2 and 2.8 trichinellae per gm.

5. Seven pigs from a garbage feeding hog ranch near San Francisco. Two pigs were mildly infected: 1.5 and 0.3 trichinellae per gm.

6. Three pigs from a hog ranch near San Francisco. Source of food, garbage from hotels and restaurants, no infections.

7. Twelve pigs from an adjacent county ranch; food sources unknown, no infections.

8. Seventeen pigs from an adjacent county ranch; food sources unknown, no infections.

9. Seventy-nine pigs from the State of Idaho; food sources unknown, no infections.

10. The most severe infection has been observed recently in a hog from a garbage feeding ranch within the city limits. In 1 gm. of pork of pillar of diaphragm were present 1,238 trichinellae; in the muscle at the base of the tongue, 1,643; and in the muscle under the scapula, 144. Home-made salami sausages contained enormous quantities of trichinellae easily demonstrable microscopically. None of them, however, were found alive by digestion and in feeding experiments.

Some information was secured in investigations of breakfast sausages by the digestion-filter method.⁴ The pork used in the manufacture of these sausages came from 20 agencies. Sausages of 5 of these (or 25 per cent) contained viable trichinellae. Examinations repeated over a longer time

would, of course, have increased this number.

Another method, based on similar principles, proved to be very useful. After digestion over night in the ordinary way, the jar is covered with 4 layers of gauze and carefully placed upside down in a funnel filled with tap water. A short piece of rubber tubing of approximately the same lumen as the stem of the funnel is slipped over the stem and closed by a clamp. After 2 hours the living trichinellae have accumulated above the clamp and are drawn off.

It is interesting to note the incidence of trichinellae in cats. The examination of 500 cats showed 54 (or 10.8 per cent) infected. The use of the digestion method is more desirable in examination of cats (and in dogs) than in other animals, because the cysts are irregularly distributed, and the slight infestations which occur may be undetected by ordinary methods. The gravity of infections generally increased with the age and size of the animals. Kittens up to the age of 6 or 7 months were found practically free.

This survey shows trichinellae quite common in certain animals in and near San Francisco, indicating definite sources from which cases of trichinelliasis may originate in man and animals.

CONTROL OF TRICHINELLIASIS *

A relative protection of the population against trichinelliasis is provided under the regulations of the meat inspection of the U. S. Department of Agriculture, Regulation 18, 4:

Inasmuch as it can not certainly be determined, by any present known method of

* The essential points outlined in this part of the paper in regard to origin and control of trichinelliasis were contained in a report to the Director of Public Health, San Francisco, dated from July 8, 1936.

inspection, whether the muscle tissue of pork contains trichinae, and inasmuch as live trichinae are dangerous to health, no article of any kind prepared customarily to be eaten without cooking shall contain any muscle tissue of pork unless the pork has been subjected to a temperature sufficient to destroy all live trichinae, or other treatment prescribed by the Chief of the bureau.

The consequences of this policy are summarized in leaflet No. 34 of the Department of Agriculture,⁵ as follows:

In the final analysis the prevention of trichinosis is a personal responsibility and involves the thorough cooking of all pork. Pork of kinds customarily eaten without cooking are also dangerous unless it is definitely known that such products were prepared in a plant operating under federal meat inspection or equally thorough state or local supervision.

In detail, this policy expresses:

1. Uncooked pork is unsafe, regardless of whether it has been inspected by federal, state or city meat inspection. It has to be made safe by thorough cooking.

2. Pork food products customarily eaten without some cooking (such as pork sausages, for instance) are unsafe, regardless of whether they have been manufactured under federal, state or city meat inspection. They have to be made safe by thorough cooking.

3. Pork food products customarily eaten without cooking are safe, if they have been manufactured in a plant operating under federal, state, or city meat inspection with adequate regulations. No further preparation is required.

4. Pork food products customarily eaten without cooking are unsafe if they have been manufactured in a plant operating without regulations adequate to insure safety.

The prevention of trichinelliasis, therefore, is a personal responsibility and involves the thorough cooking of all pork, especially as in Groups 1 and 2 above. Among 35 clinical cases of trichinelliasis observed in Boston, Spink and Augustine⁶ found only 3 which were caused by raw pork; 15 resulted from eating cooked pork sausages; 9 from boiled ham; 6 from cooked pork chops; 1 from fried ham; and 1 from cooked spare-ribs. An attempt was made in all but 3 cases to

render the pork safe by cooking, but was unsuccessful.

Ninety-nine cases of trichinelliasis in man in San Francisco resulted from consumption of undercooked breakfast pork sausages, chops, and roast; 60 from products customarily eaten without cooking.

The mistake is generally made of cooking pork or pork products inadequately. Some products, such as fried pork sausages, may lose flavor and appearance when cooked ordinarily to destroy suspected trichinellae. The National Live Stock and Meat Board says in one of its leaflets: "The flavor of pork is in the fat; therefore, pork should always be cooked at low temperatures as a high heat melts the fat and the lean is likely to be dry." Considering the low melting point of pork-fat, this is true, but this advice to use a low temperature in preparing pork favors undercooking and, consequently, outbreaks of trichinelliasis. Pork-fat has a low gravity. Pork sausages boiled in water are only partially submerged, usually because they contain a large quantity of fat. Thus, it may easily happen that trichinellae in the submerged portion may be destroyed, while those above the water-line may remain alive.

There is no regulation that breakfast sausages must be free from viable trichinellae; the responsibility rests on the consumer. It would appear logical that manufacturers prepare breakfast sausages only from pork proved to be free from viable trichinellae.

Further technical appliances should be worked out and provided for use in public eating places and homes to insure that pork or pork products be raised to 130° F., if safety against trichinelliasis is to be obtained. A false feeling of security is produced by the declaration, "Federal inspected pork," or "prepared from federal inspected pork." The public is not aware that

Government inspected pork (Groups 1 and 2) is unsafe, so far as trichineliasis is concerned. It is well to advise the public to cook pork thoroughly, but still more important how to do it.

The second part of the policy: "pork of kinds customarily eaten without cooking is also dangerous unless it is definitely known that such products have been prepared in a plant operating under federal meat inspection or equally thorough state or local supervision," refers to the pork in Groups 3 and 4. It is again left to the consumer to decide whether the product is safe. Products of Group 3 are marked with the official markings of inspection. These signs in the case of salami and mettwurst are of doubtful value to the consumer. The markings are made by authorities for authorities, and not, as it justly should be, by the authorities for the information of the buyer. The official markings of each pork food product of Group 3 should show for the buyer the words, "Guaranteed safe 'Meat Inspection. . . .'"

This would permit the purchaser to distinguish safe products of Group 3. As long as pork products of Groups 3 and 4 are found on the market, supervision of those to be eaten without cooking is necessary in the interest of safety.

So far as such products not customarily eaten without cooking are concerned (Groups 1 and 2), local authorities have today no right to interfere. Education in schools, especially in cooking schools, specific regulations in regard to eating places, and the provision of mechanical safety devices for safe cooking seem to be at present the only means of reducing danger of infections. So far as breakfast sausages (Group 2) are concerned, the urgent need to change this policy has already been emphasized.

There have occurred in San Fran-

cisco an approximately equal number of cases of trichineliasis caused by consumption of so-called "Hamburgers." Some benefit probably would result if all meat markets were to sell ground pork and ground beef or Hamburgers separately, and not (as some do at the present time) mixtures of these; and if Hamburgers sold in public eating places were required to consist of ground beef only.

A great number of cases of trichineliasis have been registered following consumption of mettwurst, salami, boiled ham, and pickled pork. Existing laws should prevent trichineliasis from such sources.

The policy of the Meat Inspection law is very definite in its purpose. It provides safe products where the consumer cannot protect himself. It frees the manufacturer of pork food products from obligations where self-protection is attainable. It fails where unchallenged infractions of the law occur on the part of pork producing agencies, and where the public fails to provide self-protection. The prevalence of trichinellae in our daily food and the occurrence of clinical cases would show higher figures than have been reported, except for the provisions of the food law. The following calculation illustrates this point: In San Francisco, there are annually slaughtered about 500,000 pigs. It may be assumed that only 2 per cent of them carry viable trichinellae. If each pig furnishes 100 meals, the imposing number of 1,000,000 trichinellae infested meals are served annually.

It is not the Meat Inspection law which has to undergo fundamental changes, but the hog raising industry. Trichinellae infections of pigs are caused by man-made conditions. Pigs kept exclusively on a vegetable diet are not liable to contract trichinellae. The majority of all pigs raised in the State of California are kept on a grain-

vegetable diet and, so far, such vegetarian fed hogs are free from trichinelliasis. The sources are found in the smaller group of hogs fed on a mixed diet of vegetables and raw or partially cooked meat, including pork, in so-called garbage.

The drive against trichinelliasis in the United States is mainly conducted by cities. Around these, piggeries are being operated, attracted by abundant, excellent, and relatively cheap food supplies. Offal from meat factories, slaughter-houses, scraps from food stores, hotels, first-grade garbage of restaurants, hospitals, military camps, institutions, garbage of railroads, and so on, are collected and utilized without further preparation in these piggeries. This offal probably includes raw pork in varying quantities. Pigs fed with this type of food become infected with trichinellae. Pork and pork food products manufactured from these animals are, in turn, responsible for infection in man. *The main source of trichinelliasis in the United States is the communities themselves offering unsafe foodstuffs for feeding pigs and failing to provide proper regulations to make this dangerous food safe.*

This mistake in policy, made on a large scale in cities, is repeated on a smaller scale in smaller communities. Wherever pigs are fed with scraps of raw pork or pork products, the danger of trichinelliasis in man becomes imminent. Since the days of Zenker, it has been emphasized that trichinelliasis is the result of the incorrect feeding of pigs.

This theory seems to give too little consideration to the rôle of rats in the propagation of the disease. Rats share in the cycle of transmission of trichinellae only in a more passive way. They become victims of the same infected food that is responsible for infection in pigs and in man. The tabu-

lations in this report make such conclusion inevitable. There is, of course, no possible place for rats as vectors and passive transmitters of trichinelliasis to pigs on hog ranches. Each infected rat represents a potential source of trichinelliasis for about 3 consecutive years.

The likelihood of transmission of trichinelliasis to hogs by feeding on carcasses of dogs and cats is undisputed. There has been argument as to whether feces of infected hogs may transmit the disease to other hogs. We feel justified in assuming that no spread of infections by feces is possible from the 3rd day after intake of the infected food. Dogs and cats discharge great numbers of trichinella larvae, seemingly unaltered and undeveloped the 1st, and possibly the 2nd day in the course of the turbulent reaction of the intestine accompanying heavy invasion of the parasite. Possibility of transmission to hogs during the short period of time is quite likely. The justification of keeping dogs and cats on hog ranches for the destruction of rodents is therefore upset by the possible danger of transmission of trichinelliasis to pigs. Rat eradication on hog ranches must not depend on dogs and cats, but on more effective poisoning.

It is not justifiable for departments of health to take over the burden of investigation of every pig in regard to trichinella infection, as by the serologic reactions advocated by Augustine and Spink.⁶ It is contended that the provision of the Meat Inspection law adjusted by the few regulations and suggestions named above, combined with sanitary management of hog ranches, provides sufficient means of dealing effectively with the present trichinella situation. In reality, sanitation of the hog ranches, strictly enforced, would make all other regulations superfluous. Some day, as fore-

shadowed in Hall's¹ summary of the situation, this may become the universal policy. At present the situation is complicated, since only a minor portion of the pork supply of a great community is derived from sources under control.

So far as San Francisco is concerned, trichinella conditions are aggravated by allowing food scraps carrying viable trichinellae to be collected in city limits to serve as hog food, without further preparation on hog ranches. Realizing that in so doing, trichinellosis is artificially propagated in pigs, to be in turn reintroduced into man, this condition can no longer be tolerated. It will become necessary to license the use of city garbage as hog food and to grant licenses only if guarantees are given that no unsafe food is used in these piggeries. To make garbage safe, sterilization of that intended for hogs seems to be required. It was unfortunate that promising negotiations conducted in 1937 between the San Francisco Department of Public Health and the agencies involved have been terminated by labor strikes. Executive Order Number 209, March 15, 1938, solves this problem. Another solution of the question would be the establishment of municipal piggeries, such as some cities have built up, in order to make garbage disposal profitable.⁷ The plant could operate in the beginning with garbage of institutions made safe by proper procedures. Later on at least part of the first-grade garbage of private institutions would be added voluntarily, if the profit of the municipal piggery were used to sustain humanitarian institutions.

Pork from pigs raised on such a piggery would be free from trichinellae, and this could be made certain by adequate inspection. Pork of this type does not at present exist on the American market.

The hog industry should become fully conscious that hog raising and pork producing are not exclusively private enterprises, but that they impose certain obligations in the interest of public health, as it is already acknowledged under similar circumstances in the dairy industry. Pork food producing agencies should try everything to provide a "healthful, wholesome, and safe meat supply" (California Meat Inspection law, section 2), an assurance not fulfilled, so far as trichinellosis is concerned.

Other Executive Orders issued by the San Francisco Department of Public Health for protection against trichinellosis are as follows: Executive Orders Nos. 215 and 216, April 2, 1938; and Executive Order Number 217, April 19, 1938.

Zoölogical gardens are an uncommon, but nevertheless occasionally important, source of trichinellosis. Since San Francisco has such an institution, we mention briefly some general rules:

1. Feeding of raw pork, even scraps of it, in garbage, and of raw dog or cat meat, should be carefully avoided.
2. Carcasses of animals of the zoo, and especially those of flesh-eating animals, should not be buried or used as food for other animals, but should be incinerated.
3. Utilization of the meat of any flesh eating animal, and particularly of bear or badger, for human consumption makes special investigation for absence of trichinellae indispensable.
4. Methods of rat control as used on hog ranches.

SUMMARY

The relative protection intended by the Meat Inspection law against trichinellosis in man has to be made more effective and, in addition, the spread of trichinellosis to pigs prevented by the following means:

1. *Sanitation in management of hog ranches:*
 - a. Licensing garbage feeding under the provisions of rendering garbage safe by technical methods.

- b. Extermination of rats (ratproof buildings, poisoning).
 - c. Freeing of hog ranches from cats and dogs.
2. *Trade regulations:*
- a. Exclusion of pork food products of Group 4 from the market.
 - b. Breakfast sausages should be manufactured from safe pork.
 - c. Limited trichinella inspection for manufactured pork food products is desirable.
 - d. Safe products should carry declaration: Guaranteed Safe, Meat Inspection of Department of Public Health.
 - e. Labels: "Prepared from . . . inspected meat" are not advisable on products of Group 2.
 - f. Clearly visible inscription on sales of pork: *Cook Pork Thoroughly.*
3. *Education of consumer:*
- a. In regard to occurrence of trichinellae in food and dangers of raw or undercooked pork and pork food products.
 - b. How to avoid undercooking.

4. *Instructions to personnel of eating places—similar to those for consumers:*

Mechanical safety devices.

Hamburgers are to be made from beef only.

An Epidemic of Typhoid Fever Attributed to Salad Contaminated by a Chronic Typhoid Carrier

PAUL A. LEMBCKE, M.D., AND PAUL VON HAESSELER, M.D.
State Department of Health, Albany, N. Y.

EACH of 3 cases of typhoid fever reported during the third week of June, 1937, in individuals rather widely separated as to residence was investigated independently by the health agency* in whose jurisdiction the case occurred. The New York State Department of Health was notified of the occurrence and result of investigation of each case. Study of the reports revealed the common factor that all 3 individuals had attended a luncheon served on Memorial Day by a fraternal organization in Schenectady.

An immediate survey of recent admissions to Schenectady hospitals was undertaken and disclosed 2 additional cases of illness characterized by continued fever which were suspected of being typhoid fever, the diagnosis of which was subsequently confirmed by laboratory evidence. Both individuals had attended the luncheon on Memorial Day.

The almost simultaneous occurrence of 5 cases of typhoid fever in residents or visitors to Schenectady was a definitely unusual prevalence of the disease, the average annual number of cases in Schenectady for 1932-1936 being 2. The fact that all 5 had at-

tended the Memorial Day luncheon strongly suggested an etiological relationship of some factor connected with the luncheon. A detailed investigation was undertaken jointly by the Schenectady City Department of Health and the New York State Department of Health.

CLINICAL INVESTIGATION

The names and addresses of persons who attended the luncheon were obtained, and each individual was visited by a member of the medical staff of the State Department of Health. In all, 33 persons attended the luncheon and 2 were discovered who did not attend but who ate food brought home from this function. All but 2 of the 35 were interviewed. If the questioning revealed symptoms suspicious of typhoid fever, 3 fecal specimens and one or more of blood were obtained for laboratory examination. In the absence of symptoms a single fecal specimen was secured. Three fecal specimens were obtained from all persons known to have supplied or prepared food for the luncheon.

During the investigation 4 new cases were reported and 4 hitherto unknown cases were discovered, making 13 cases among those who attended the luncheon. The Widal was positive in all 13 cases.

* Schenectady City Department of Health, New York State Department of Health District Office, and Massachusetts State Department of Health.

One patient died before a fecal specimen was obtained; typhoid bacilli were isolated from the feces of 9 of the 12 cases from whom specimens were secured. Typhoid bacilli were cultured from the blood of one patient who had negative fecal cultures. Of the total number, 9 were residents of Schenectady and 4 were non-residents. In addition to the 13 clinical cases, 2 sub-clinical cases or passive typhoid carriers were detected. A positive Widal and positive fecal cultures were obtained from both individuals, although there was no history of previous typhoid fever and neither exhibited the symptoms nor physical signs of the disease. That the carrier condition in these two was of temporary duration was demonstrated by repeated bacteriological studies. A positive Widal was reported in one individual who gave no history of previous typhoid fever or vaccine and who suffered no symptoms of the disease; repeated fecal cultures were negative. With the exception of this person, positive Widal tests were not found in other than the clinical cases and temporary passive carriers of typhoid bacilli.

None of the individuals interviewed had ever received typhoid vaccine. Two gave a history of previous typhoid fever; neither became ill and the laboratory examinations were negative.

CLINICAL CHARACTERISTICS

The clinical course was prolonged and severe in 6 cases, and 1 death occurred; a girl aged 16 years. The other cases were relatively mild; in fact, 4

were not recognized prior to the epidemiological investigation as having typhoid fever. In addition to these 13 clinically recognizable infections, there were the 2 sub-clinical cases or temporary passive carriers, and the 1 individual with a positive Widal, who have been described above.

Three of the 13 cases became chronic carriers, women, aged 44, 53, and 65, respectively. Each has been found to excrete typhoid bacilli in the feces over a period of more than a year following the illness.

INCUBATION PERIOD

The interval between the luncheon and the onset of symptoms varied from 5 to 28 days. The peak incidence was reached on the 7th day, when 5 cases occurred; the median case fell on the 9th day. The chronological distribution of cases is shown in Table I.

FOOD SOURCE

Detailed information was obtained as to the various foods eaten by each individual who attended the luncheon. Table II lists the foods, and shows the consumption of each type by the 15 infected and by the 17 who did not show evidence of infection. Potato salad, macaroni salad, buttered rolls, and coffee were the only foods eaten by more than 5 of the patients.

Of the home prepared foods, 2 persons each supplied one dish of potato salad; 1 person provided two dishes of potato salad, and 1 of macaroni salad; 4 cakes were contributed by different persons; 1 person supplied cabbage

salad; a dish of baked beans was furnished by another, and a jar of pickles was provided by one. The remaining articles—tinned evaporated milk, coffee, sugar, butter, rolls, and cold sliced meats—were purchased from various stores in Schenectady.

Serving spoons were placed in the dishes contributed and each guest helped himself. The only food prepared at the church was the rolls, which were buttered just before the luncheon. Of the 5 women who did this, 4, all of whom were well at the time, subsequently developed typhoid fever; the 5th gave no history of previous typhoid fever; her Widal was negative; and 3 fecal cultures on successive days were negative.

Four of the 10 persons who prepared food at home developed typhoid fever subsequent to the luncheon. The date of onset could be fixed with a considerable degree of certainty in each—first symptoms appeared from 5 to 11 days after the luncheon.

Two of the 6 persons who prepared food and who did not contract typhoid fever gave a history of previous typhoid fever; 3 or more negative fecal cultures were obtained from each. Of the 4 who prepared food but did not develop the disease and who gave no

history of previous typhoid fever, 3 each submitted 3 or more negative fecal specimens. *B. typhosus* was isolated from the feces of the remaining individual on 12 different occasions over 3 months following the luncheon.

The individual with positive fecal cultures, M. T., a woman 65 years of age, denied having had clinically recognized typhoid fever at any time.* She recalled, however, that about 40 years previously, her sister suffered from a disease which was probably typhoid fever, and that, although she was living in the same household, she herself did not become ill. For the past 10 or 15 years, M. T. had suffered symptoms which might be ascribed to chronic cholecystitis. She had never had children, her occupation had never involved the preparation of food for others, and there was no history of her ever having given rise to a case of typhoid fever previous to this epidemic.

Despite the finding of typhoid bacilli in many fecal specimens submitted at intervals over 3 months, and a negative Widal reaction on the 43rd day following the luncheon, the possibility that

* Twenty per cent of known chronic typhoid carriers in New York State deny previous history of typhoid fever.

M. T. was not a typhoid carrier prior to the luncheon but had developed sub-clinical typhoid and the carrier condition subsequent to the luncheon might be raised were it not for the epidemiological evidence incriminating her.

On the evening of May 30, M. T. peeled and boiled potatoes which were set aside until the following day. Early in the morning of the day of the luncheon, the potatoes prepared the previous evening, and a dish of macaroni boiled the same morning, were cut up, celery and a prepared mayonnaise dressing were added, and the ingredients stirred and mixed with the fingers. Two dishes of potato salad and one of macaroni salad were set aside for several hours at room temperature, and shortly before noon taken to the church parlors to be served at the luncheon. A small amount of each salad was left at home for the evening meal.

This was the only macaroni salad served at the luncheon. Eleven of the 15 persons known to have been infected (either clinical cases or passive carriers) gave a definite history of having eaten this salad; one other patient stated she had probably eaten it. Two of the four dishes of potato salad were prepared by M. T. Twelve of the 15 infected persons stated definitely they had eaten potato salad, and 2 others stated they had probably eaten of it. Altogether, 14 of the 15 gave a definite history of having eaten potato salad or macaroni salad, or both; the remaining patient felt it was very probable she had eaten of both.

At the conclusion of the luncheon, some of the potato salad prepared by M. T. remained, was taken home by one of the women present, and served to her son and niece. The son developed typhoid fever on June 25, but the niece was apparently not affected.

A young man who rented a room in the home of M. T. attended the luncheon but denied having eaten either potato or macaroni salad, preferring baked beans, as did the majority of men attending. However, in the evening of the day of the luncheon, he ate in the home of M. T. a portion of the salads which had been left at home since morning. On the basis of a positive blood agglutination test and the presence of typhoid bacilli in a fecal specimen submitted July 4, he has been considered a temporary passive typhoid carrier; several fecal cultures subsequent to that of July 4 have been negative. The remainder of the salad left at home was eaten by M. T. and her husband. The latter suffered from "grippe" and vague intestinal symptoms for 2 or 3 days about 2 weeks after the meal; fecal culture was negative 34 days later, and the Widal test, made 45 days after the meal, was negative.

The fact that macaroni salad prepared by M. T. was eaten by at least 10 of the typhoid fever patients; that potato salad was eaten by at least 11 of the 13, and that M. T. prepared two of the four dishes of potato salad; that 12 and probably all 13 of the patients ate potato salad, macaroni salad, or both; that 2 of the patients ate M. T.'s salad elsewhere than at the luncheon; and that repeated fecal cultures submitted by M. T. over 3 months have contained typhoid bacilli makes it extremely probable that, even in the absence of a history of previous typhoid fever, she was a chronic typhoid carrier and the source of the outbreak. The vehicle of infection was potato salad and macaroni salad prepared by the carrier.

SUMMARY AND CONCLUSIONS

1. Three cases of typhoid fever in individuals rather widely separated as to resi-

dence were reported by 3 different health departments to the New York State Department of Health. Prompt reporting, followed by epidemiological investigation, made possible the early recognition of an outbreak of typhoid fever and the institution of steps to detect the source and prevent its spread. The importance of prompt reporting by physicians and health officers of what may seem to be individual and apparently isolated cases is illustrated by this outbreak.

2. Thirteen clinical cases of typhoid fever were found to have occurred among 35 persons who had eaten food prepared for a community meal to which articles were contributed by 10 different persons.

3. In addition to the 13 clinical cases, 2

temporary passive carriers of typhoid bacilli were detected by routine laboratory examination. An additional person was found to have a positive Widal in the absence of symptoms and history of typhoid fever or vaccine; fecal cultures were negative.

4. Three of the clinical cases were found to have passed from the acute stage into the chronic typhoid carrier condition. All 3 continue to excrete typhoid bacilli for more than a year after the onset of typhoid fever.

5. No secondary cases occurred as a result of the epidemic.

6. Detailed epidemiological studies identified the vehicle of infection as macaroni and potato salads, and the source as a previously unrecognized chronic fecal typhoid carrier.

Yellow Fever in Brazil

AS to the general situation in regard to yellow fever in South America the observations of the last 3 months show in a striking way the importance of jungle fever as a public hygienic problem of the first order. An enormous area covering parts of the States of Minas Geraes and Rio-de-Janeiro have been infected during this year (1938). The value of viscerotomy has been again shown. All of the early cases of the present epidemic have been discovered by viscerotomy, although many of the physicians of this region were familiar with the literature concerning jungle fever.

The present outbreak in the States of Minas Geraes, Rio-de-Janeiro, and Sao Paulo have been associated as have been those in recent years in Brazil with a high mortality in howler monkeys. This

observation has been confirmed by the discovery of dead monkeys in the forest. The result of many thousands of protection tests with the serum of wild animals begun in 1934, confirm the opinion that the various varieties of monkeys are the most important vertebrates in the dissemination of the jungle virus. The collection of insects in the many infected zones also confirm the idea that several species of mosquitoes are the active vectors of the virus when most of the human cases are produced. However, it has not yet been possible to determine the method by which the virus is concerned from season to season in the south of Brazil where each year a number of months pass without a single human case being observed.—F. L. Soper, *Month. Bull.*, Office International d'Hygiène Publique, June, 1938, p. 1205.

Dye Concentration in Culture Media Employed for the Analysis of *Escherichia-Aerobacter* Members in Milk*

HERBERT D. MCAULIFFE AND M. A. FARRELL

*Division of Bacteriology, The Pennsylvania State College,
State College, Pa.*

RECENT investigations¹ have indicated that one of the limiting factors in tests to determine the presence of *Escherichia-Aerobacter* members in milk has been the culture media employed. In most instances the concentration of the bacteriostatic agents in these media was developed for use in water analysis. Assuming the possibility of most of the dyes used as bacteriostatic agents being adsorbed on the milk solids, leaving only a fraction of the original concentration free for inhibitory purposes, studies were undertaken to determine a more desirable dye concentration for culture media employed in the detection of the *Escherichia-Aerobacter* group of organisms in milk.†

In view of the earlier results obtained in this laboratory¹ which indicated that fuchsin lactose broth, brilliant green lactose bile broth 2.0 per cent, and methylene blue brom cresol purple broth were equally efficient in the de-

tection of *Escherichia-Aerobacter* members in milk, the media selected for this study were fuchsin lactose broth and brilliant green lactose bile broth 2.0 per cent. The third medium was omitted because of its relative complexity.

*Standard Methods of Water Analysis*² recommends a concentration of 1 part of 95 per cent basic fuchsin dye in 66,666 parts of lactose broth. In this study it was verified that an increase in the basic fuchsin dye content above that recommended was inhibitory to the growth of aqueous suspensions of colon group members. However, skim milk suspensions of the same organisms were not inhibited by a basic fuchsin ‡ dye concentration of 1 part in 13,300 of lactose broth.

These results with skim milk failed to take into consideration the possibility of dye being adsorbed on the fat globules of whole milk. Further studies were undertaken, therefore, employing whole milk of varying percentages of fat and serum solids, to determine the concentration of dye necessary in the

* Authorized for publication on June 20, 1938, as paper No. 840 in the Journal Series of the Pennsylvania Agricultural Experiment Station.

† Studies not here reported show that Gram-positive organisms multiply readily in these media with their present dye content in the presence of the organic materials of whole milk.

‡ The dye content of the basic fuchsin and brilliant green dyes employed in this study was 35 and 95 per cent respectively and was approved as satisfactory by the Commission on Standardization of Biological Stains.

Figure I

presence of whole milk which would permit a free dye concentration of 1 part in 66,666, as recommended by *Standard Methods of Water Analysis*.²

Whole milk containing 4.0 per cent fat and 8.0 per cent serum solids was added to lots of lactose broth of varying dye content in a ratio of 1 part milk to 10 of the medium. The concentration of free dye present after adsorption was determined by placing the mixture inside a semi-permeable membrane and allowing the dye to dialyze for 48 hours at 37° C. into a standard medium containing 1 part dye in 66,666 parts of lactose broth. A free dye concentration less than the standard resulted in a movement of dye inward and decreased the dye concentration outside of the membrane. Conversely a con-

centration greater than the standard resulted in an increased concentration of dye outside of the membrane. Only when the free dye concentration of the milk and medium mixture was equal to the standard of 1 part in 66,666 was there no change in the concentration of dye outside of the membrane.*

Figure I shows that, as the concentration of dye mixed with the milk was increased, the concentration of free dye after adsorption also increased to plot as a straight line. When the concentration of dye in the medium mixed with the milk was increased to 1 part in 9,500 (see broken line), the free dye content was approximately 1 part

* All dye concentrations after dialysis were determined colorimetrically.

in 66,666 as noted by the horizontal line. In order to have a free dye concentration of 1 part in 66,666 as recommended² in the presence of whole milk, 4.0 per cent fat and 8.0 per cent serum solids, it is necessary to have a concentration of 1 part in 9,500 in the medium before adding the milk.

Similar studies were conducted employing a milk abnormally high in organic matter, 6.0 per cent fat and 12.0 per cent serum solids. It was found necessary to increase the dye concentration to 1 part in 8,250 to give a free dye concentration at 1 part in 66,666. Conversely a low solids milk 3.0 per cent fat and 6.0 per cent serum solids required a dye concentration of only 1 part in 14,800.

*Standard Methods of Milk Analysis*³ recommends the use of brilliant green lactose bile broth 2.0 per cent as a presumptive medium in the detection of *Escherichia-Aerobacter* members in milk. The concentration of brilliant green is the same as recommended by *Standard Methods of Water Analysis*;² 1 part of certified brilliant green in 75,188 parts of lactose bile broth 2.0 per cent. The optimum concentration of brilliant green in brilliant green lactose bile broth 2.0 per cent for use in detecting *Escherichia-Aerobacter* members in milk was determined by dialysis as previously described. Results indicate that a concentration of 1 part of brilliant green in 30,000 is necessary in the medium to obtain the recommended concentration in 75,188 for bacteriostatic action in the presence of whole milk solids, 4.0 per cent fat and 8.0 per cent serum solids.

A comparison was then made to observe the relative efficiency of 4 culture media in the detection of *Escherichia-Aerobacter* members in the presence of whole milk solids. Two of these media contained the concentration of dye recommended in *Standard Methods* and in the remaining 2 the concentration

that was found in this study to be more favorable. These media are:

1. Fuchsin lactose broth, 1 part basic fuchsin in 66,666
2. Fuchsin lactose broth, 1 part basic fuchsin in 9,500
3. Brilliant green lactose bile broth 2.0 per cent, 1 part brilliant green in 75,188
4. Brilliant green lactose bile broth 2.0 per cent, 1 part brilliant green in 30,000.

These media were inoculated with 5 pure cultures of the colon group suspended in coli-free whole milk in various dilutions. Five tubes of each medium were inoculated with 1 ml. of each dilution of each culture. The tubes were incubated 48 hours and positive tubes recorded on the basis of gas production. The medium containing 1 part basic fuchsin in 66,666 gave 154 positive tubes, while the medium with 1 part in 9,500 gave 161, showing that the increased concentration of dye gives a more efficient medium. Both 1 part in 75,188 and 1 part in 30,000 brilliant green gave 155 positive tubes, indicating that the increased concentration is just as efficient for *Escherichia-Aerobacter* members as the lower.

To determine the relative efficiency of the 4 media in inhibiting false presumptive organisms in the presence of whole milk solids, the same procedure was followed, using 2 cultures of the genus *Bacillus* capable of fermenting lactose with the production of gas. In this case, 1 part in 66,666 basic fuchsin gave 52 positive tubes, while 1 part in 9,500 gave only 6 positive tubes and 34 with small bubbles, showing that the increased concentration of basic fuchsin is more inhibitive to these microorganisms which are responsible for false presumptive tests. One part in 75,000 brilliant green gave 2 positive tubes and 18 showing small bubbles, while 1 part in 30,000 gave no positive tubes and no bubbles, again showing the increased dye concentration to be

more inhibitive to these Gram-positive lactose fermenting organisms.

The ability of these 4 media to serve as selective media in the detection of *Escherichia-Aerobacter* organisms in milk samples containing several types of bacteria was studied by inoculating them with 70 milk samples collected at a local receiving station. Five tubes of each medium were inoculated with 1 ml. portions of milk and positive tubes confirmed with regard to the presence of *Escherichia-Aerobacter* members by employing eosine-methylene-blue and making the "completed test" in accordance with "Standard Methods Procedure."²

The medium containing 1 part in 9,500 basic fuchsin when used as a presumptive medium showed that 53 of the 70 samples contained *Escherichia-Aerobacter* members, all of which were confirmed and found positive on completion. The medium containing the lower concentration of basic fuchsin, 1 part in 66,666, revealed only 43 of the 53 positive samples as containing colon group members. The brilliant green lactose bile broth 2.0 per cent medium with 1 part in 75,188 brilliant green detected only 46 samples showing *Escherichia-Aerobacter* members, compared to the medium containing 1 part in 30,000 brilliant green, which showed 51 positive samples. These results indicate that the increased concentrations of dye are more sensitive in detecting *Escherichia-Aerobacter* members in milk.

The higher concentrations of basic fuchsin and brilliant green in no case permitted the growth of false presumptive microorganisms. However, with both dyes the lower concentrations showed gas from 5 samples, which could not be confirmed as being positive on completion; again indicating that the increased concentration of dye is more effective in inhibiting the growth of non-colon group microorganisms.

DISCUSSION

The results obtained in this study indicate that in the employment of these "Presumptive Tests" media for the detection of *Escherichia-Aerobacter* members in milk, the milk solids adsorb a considerable amount of the dye present. The proportion of dye in these two media was originally determined by incorporating the (greatest) maximum dye content to serve as a bacteriostatic agent for Gram-positive bacteria which at the same time would not inhibit the growth of Gram-negative organisms. In the case of fuchsin lactose broth the maximum amount of dye which could be incorporated was 1 part in 66,666. These studies show that when 1 ml. portions of whole milk (4.0 per cent fat, 12.0 per cent total solids) were added to fuchsin lactose broth, the dye concentration could be increased approximately 7 times to a concentration of 1 part in 9,500 without inhibiting the growth of colon group members. In a similar manner it was demonstrated that the content of brilliant green in brilliant green lactose bile broth 2.0 per cent could be increased approximately 2½ times, or from a concentration of 1 part in 75,188 to 1 part in 30,000.

As a result of the adsorption of fuchsin dye upon the milk solids there is less dye present to act as an inhibitory agent and Gram-positive organisms multiply readily in fuchsin lactose broth with its present dye content. Previous studies (1) indicated that these 2 culture media when used for the detection of *Escherichia-Aerobacter* members in milk gave 20 per cent of false presumptive tests. The present study, employing pure cultures of bacteria as well as 70 milk samples, shows that by increasing the dye content in these 2 media the false presumptive tests are largely eliminated without lessening the selective properties of these media for the *Escherichia-Aerobacter* group.

SUMMARY

1. The addition of 1 ml. portions of milk to fuchsin lactose broth and brilliant green lactose bile broth 2.0 per cent adsorbed a considerable amount of the dyes present, thereby lessening the selective action of these media in the detection of the *Escherichia-Aerobacter* group of organisms in milk.

2. To obtain the proper amount of free dye so that these culture media can serve in a selective capacity it is necessary that the content of basic fuchsin in fuchsin lactose broth be increased approximately 7 times, from 1 part in 66,666 to 1 part in 9,500, and the con-

tent of brilliant green dye in brilliant green lactose bile broth 2.0 per cent be increased approximately $2\frac{1}{2}$ times from 1 part in 75,188 to 1 part in 30,000.

Medical Research in Canada

SCIENCE announces that a survey of existing facilities for medical research in Canada is to be made under the auspices of the Committee on Medical Research, established in March, 1938, by the National Research Council. Sir Frederick Banting is chairman of the committee and will personally conduct the survey.

Among other members of the committee are those with special interest in public health including Dr. R. E. Wodehouse, Deputy Minister, Department of Pensions and National Health, Ottawa, and Dr. A. Grant Fleming, Dean of the Faculty of Medicine and Professor of Public Health, McGill University, Montreal.

Bovine Mastitis

The Relation of Streptococci to Physical Changes Occurring in the Udders of Dairy Cows

W. T. MILLER AND H. W. JOHNSON

*Bureau of Animal Industry, U. S. Department of Agriculture,
Beltsville, Md.*

THE anatomical changes which develop in the bovine udder as a result of mastitis offer one of the most satisfactory means available at the present time of determining whether the organ is diseased and how far the disease has progressed. When mastitis has been present in a quarter for even a relatively short time the character of the udder tissue becomes appreciably altered. The changes which are found on clinical examination of a diseased quarter may be either in the form of distinct firm nodules or diffuse thickening of the glandular tissue. The lesion in either case represents an invasion of the normal secreting tissue by connective or scar tissue following inflammation of the gland. If the mastitis is only transient in nature, the proliferative process becomes static, but the indurations remain as a permanent record of the attack. Unfortunately, the majority of the cases of mastitis are caused by bacterial invasion, and as a rule the infection establishes itself permanently in the udder. In this event, the disease tends to progress with varying degrees of rapidity from the original site of localization, usually the cistern, to the rest of the quarter. Induration of the glandular tissue accompanies this progression until in

many cases there is practically a complete replacement of the secreting tissue by scar tissue.

In view of the permanence of the changes which occur as a result of mastitis and its accessibility for examination, palpation of the empty udder affords an easy and accurate means of detection of the disease. Some of the possibilities inherent in this method have been recognized in the past by a number of authors¹⁵ and Udall and Johnson²⁰ have observed that "the value of a physical examination in diagnosis (of mastitis) rates above any other single method." That the milk from udders which are definitely indurated is usually changed in composition as shown by other tests; such as pH, chlorine, catalase and leucocyte count, has been observed in the course of mastitis investigations in this laboratory and this fact has also been reported by Hucker and Udall.¹⁰ On the other hand, when milk samples from these udders are examined bacteriologically, bacteria which are not customarily associated with mastitis are not infrequently found. Also a few udders have been encountered which appear to be entirely normal on palpation and are harboring mastitis streptococci.

As a result of the rather extensive investigation of mastitis by a number of workers in the past, a number of species of bacteria have been described as the causative agents of the disease. It is fairly well agreed at the present time, however, that the streptococci are of chief importance in this respect and that one definite species, *Streptococcus agalactiae*, is found in a high percentage of the cases of this type of mastitis. The incidence frequently reported for this species has been around 90 per cent.^{8, 17} Several species of streptococci comprise the remaining 10 per cent, but probably because of their relatively infrequent occurrence, the information concerning them is somewhat limited. Other species of cocci, more particularly staphylococci are also found in some cases of mastitis, but comparatively little knowledge is available relative to their importance in the disease. More recently however, reports^{5, 6, 11, 12, 18} have appeared which indicate an increasing interest in this phase of the problem. The remaining bacterial species, consisting principally of bacilli, such as coliform types, *Corynebacterium pyogenes*, and others, are of minor importance probably because of the sporadic character of their occurrence. It is worthy of note in this connection that the changes induced by these various agents in the udder and the milk are very similar.

The object of this work therefore was to compare the physical condition of the udders of infected and uninfected cows in herds in which mastitis streptococci were present and also to compare the udders of cows in streptococcus-free herds with these animals. In addition an attempt was made to identify the species of streptococcus in each animal so infected. Several different types of herds in the vicinity of Beltsville, Md., were included in the investigation which was started in the fall of 1935. Three of these herds,

numbers 1, 2, and 9 (Tables II and V) are maintained to supply fluid milk to institutions. Two other herds, numbers 3 and 5, are used principally for experimentation in breeding and feeding problems of dairy cattle. The remaining four herds, numbers 4, 6, 7, and 8, are privately owned and are subject to health department supervision. In addition to milk production, herd number 4 is used for breeding pure bred cattle.

PROCEDURE

Composite samples of milk were collected from each animal immediately before milking. The ends of the teats were washed thoroughly with a pledget of cotton, moistened with a 1 in 1,000 solution of bichloride of mercury in 50 per cent alcohol. Several streams of milk were discarded from each quarter and then as equal amounts as possible were drawn from the four quarters into a sterile screw top specimen vial, holding about 20 c.c. When the samples were brought to the laboratory, part of the milk was immediately tested by the Hotis method,⁹ and the remainder was incubated for 24 hours at 37° C. in the original container. At the end of this time, the results of the Hotis test were noted and smears made from the incubated milk for microscopic examination. In addition a large loopful (4 mm. loop) of incubated milk was spread over the surface of a blood agar plate (5 per cent horse blood) which had been prepared previously. The plates were incubated for 24 hours at 37° C., and the colonies which resembled streptococci were picked into 10 per cent serum (horse) bouillon. These cultures were examined microscopically for purity following incubation and then seeded in differential culture media.

One-tenth c.c. of culture was added to each of the following media: litmus milk, methylene blue milk (1 in

10,000), lactose, salicin, mannite, trehalose, sorbitol, aesculin, and sodium hippurate. The media for the fermentation tests were made by adding 1 per cent of the carbohydrate to extract broth together with 10 per cent serum (horse) and Andrade's indicator. The solution was adjusted to pH 7.4, sterilized by filtration, and tubed in 2 c.c. amounts. Each medium was incubated for 48 hours at 37° C., to test for sterility. The sodium hippurate medium was prepared according to the pepsin-peptone formula recommended by Ayers and Rupp.¹ Ability to split aesculin was determined by the method described by Weatherall and Dible.²¹ The reactions of the streptococci in these test substances were recorded after 5 days' incubation at 37° C. All of those cultures which failed to give typical reactions for *S. agalactiae* (group A, Table I) were tested a

second time after an interval of several months as a check on the results noted at the time of isolation.

Each udder was examined clinically as soon as possible after it had been milked out. Classification of the udders follows the plan described by Udall and Johnson²⁰ in so far as the physical condition of the organ is concerned. The brom-thymol-blue test was not used and the previous history of the animal was not considered. In this classification, a cow is placed in Class 1 when all quarters are entirely normal and free of indurations. When one or more quarters have some slight change in the consistence of the glandular tissue which may be in the form of a minimum diffuse or nodular thickening, usually in the lower part of the gland, the cow is placed in Class 2. If one or more quarters of the udder contain distinct indurated

areas either diffuse or as nodules, but with a considerable part of the glandular tissue remaining intact, the cow is classed as number 3. A cow is considered to be in Class 4 when a major portion of the secreting tissue has been replaced by connective or scar tissue.

RESULTS

A total of 629 lactating cows in 9 dairy herds have been examined in the course of this investigation. Streptococcic mastitis was found in 5 herds, containing 547 animals (Table II) while no streptococci were detected in the remaining 4 herds with 82 cows (Table V). The number of cows found to be excreting streptococci with the milk by one or more of the tests was 298, or 47.4 per cent of all animals examined. This result is more or less comparable to those reported by other authors.¹⁵ The highest incidence of infection occurred in the largest herds, numbers 1 and 2, with percentages of 63.1 and 61.0 respectively (Table II), while the lowest percentage, aside from herds which were completely free and which might be considered in another category, was 32.0 in herd 5 with only 25 animals. Herds 3 and 4 had been found to have a somewhat larger num-

ber of animals infected at the time of previous examinations, but owing to disposal of older animals and their replacement with heifers, the incidence of infection has been materially reduced, particularly in Herd 4.

Of the 298 samples (Table II) in which streptococci were detected by one or more of the tests, cultures were recovered from 276, or 90.2 per cent. The different types of streptococci which were isolated have been divided into three large groups (Table I) on the basis of their action on sorbitol and trehalose² and these groups further sub-divided with respect to the results in the other media employed. As a consequence, 7 more or less distinct types have been formed. Because of certain differences in the composition and kinds of media used, it is somewhat difficult to compare the results of other authors in connection with the bacteriology of the streptococci. However, there can be relatively little doubt that Group A in Table I is *S. agalactiae* which has been described under that name by some authors^{7, 19} and Group 1 A¹⁶ and Group 1⁴ by others. On the other hand, the similarity of the remaining strains found in this work with those reported elsewhere is not as

clear. As far as can be determined, Groups B, C, and F have not been reported in other publications dealing with this subject. Group D appears similar in many respects to *S. uberis* described by Diernhofer³ which is listed as Group 3 in the classification of Plastring and his associates.¹⁶ Group E likewise may be said to resemble Group III of Edwards.⁴ Failure by Group G strains to acidify trehalose is the only cultural difference between them and Group A. Inasmuch as approximately half of the cultures in Group G showed definite evidence of fermentation of trehalose when tested a second time several months after isolation, some question might be raised concerning their inclusion in a separate group rather than placing them in Group A. The irregularity of trehalose fermentation has also been noted by Plastring *et al.*¹⁶ who have, however, given similar strains a separate classification. It will be observed in Table I that Group G strains have been found in but 2 of the 5 infected herds, numbers 1 and 5 (Table I). In the former, 56.1 per cent of the streptococcus cultures isolated belonged in this group, whereas in the latter herd all but one animal were found to be carrying this strain. In Table II, animals carrying Group G streptococci have been included with those carrying typical *S. agalactiae* or Group A types for convenience in tabulation.

The results of physical examination

of the udders of 617 cows appear in Table III. Twelve additional animals were not examined because of too recent freshening and an accompanying edema of the udder which rendered the organ unsuitable for palpation. The figures presented in Table III are instructive with respect to the influence of streptococci on the udder and also as to the condition of the udders of cows which are not so infected. Although the total number of animals in each group is approximately equal, 2.4 per cent of the infected animals had udders in which no indurations were found and were placed in Class 1 while 11.6 per cent of the uninfected animals fell in this class, a difference of almost 5 to 1. There were 18.2 per cent of the infected animals in Class 2 and 29.4 per cent of uninfected animals which is a ratio of not quite 2 to 1. No significant difference was apparent between the percentage of animals in the two groups found to be in Class 3, although a slight advantage was noted for the uninfected group. In Class 4, however, the difference is considerable in that 24.7 per cent of the infected cows showed marked physical evidence of mastitis in one or more quarters as contrasted with 9.2 per cent for the uninfected group, or about two and one-half times as many. The fact that the percentage of cows in the two groups not infected with streptococci is nearly the same in all 4 classes would appear to emphasize the damaging

TABLE III

Summary of Average Results of Classification of Udders of Cows in the Several Herds by Physical Examination

- 1. Five additional cows not palpated
- 2. Seven additional cows not palpated

effect of these organisms and may also possibly indicate some other common cause for the fibrosis present in non-streptococcus udders.

The physical condition of the udders found in the different herds is shown in Tables IV and V. Although there is considerable variation in this respect in both groups, it will be noted that when individual herds are considered, the uninfected ones do not show the amount of change in the udders found in those which are affected with streptococcic mastitis. It should also be pointed out that the largest number of Class 4 cows occurred in Herd 2 which was also found to have the highest incidence of infection with *S. agalactiae*, 94.4 per cent (Table II), and that as the number of animals carrying these streptococci decreases in the first 4 herds, the number of cows in Class 4 becomes smaller. Under the circumstances, it would appear that this result, although interesting, may be more or less co-

incidental since the percentages in the other classes do not support it.

Because of the comparatively small number of animals in the 4 herds in which streptococci were not found, considerable fluctuation appears in the individual herd percentages. Inasmuch as no definite cause could be determined for the changes present in these herds, it may be possible that local conditions were of considerable influence in this matter. In Herd 9, as an example, several animals with udders showing marked evidence of mastitis and also carrying streptococci had been eliminated several years prior to this survey and replacements made with first-calf heifers from the herd. However, the percentages for these herds are in fairly close agreement with the uninfected cows (Group B, Table VI) in the infected herds. In Table VI, the physical condition of the udders in the infected (A) and uninfected (B) groups in the same herd are compared.

TABLE V

Classification of Udders of Cows in Streptococcus-Free Herds by Physical Examination

Herd Number	Number of Milking Cows in Herd	Class 1		Class 2		Class 3		Class 4

5	A	8	0	0.0	1	12.5	7	87.0	0	0.0
	B	17	3	17.6	4	23.5	9	52.9	1	5.9

A = Infected animals

B = Uninfected animals

* Cows included from which streptococci were not isolated

1. 3 additional cows not palpated

3. 4 additional cows not palpated.

2. 2 additional cows not palpated

4. 3 additional cows not palpated

Since all of the animals in each herd are maintained under the same conditions the results in this table are of considerable significance. The percentage of uninfected cows in Classes 1 and 2 is uniformly higher by a large margin, while the number of streptococcus-infected cows in Class 4 is two to three times that of the uninfected animals. It may be possible that the somewhat closer agreement between the uninfected animals in the different herds with regard to class percentage may be attributed to the larger numbers in each herd.

DISCUSSION

The results of the bacteriological study of milk samples in this investigation agree fairly well with the reports of other workers.¹⁵ Figures somewhat higher than the 47.4 per cent infection with streptococci have been found in some cases while in others the percentage has been lower. Also the number of cows, 83.3 per cent carrying *S. agalactiae* in one or more quarters

approaches the previously mentioned figure of 90.0 per cent. This slightly lower percentage is due to the findings in one herd (number 1, Table II). If this herd is not considered, the percentage becomes 92.6. A number of types of streptococci were encountered in Herd 1, Table I, most of which have been described by other authors. The type of streptococcus most prevalent in this herd, however, resembled *S. agalactiae* in all respects with the exception of its failure to act on trehalose (Group G, Table I). This same variety was also practically the only one present in Herd 5 (Table I). Although it seems probable that these streptococci may be *S. agalactiae* or closely related to it, it is of interest to note that the percentage of cows with Class 4 udders in these herds is appreciably smaller than in those herds having a high percentage of cows infected with typical *S. agalactiae*.

Very few figures are available with which the results of the clinical examination of the udder can be directly

compared. It is therefore not known whether the figures of 7.3 per cent, Class 1, or normal udders; 24.1 per cent, Class 2, or slightly indurated udders; 52 per cent, Class 3, or distinctly indurated udders; and 16.5 per cent, Class 4, or udders with marked induration would be approximated in an examination of an equal number of cows elsewhere. In connection with the percentage of Class 4 animals, however, some figures reported by the Bureau of Animal Industry^{13, 14} several years ago are of interest. At this time 235,354 milk cows were examined for marked physical evidence of mastitis, and 28,439, or 12.0 per cent, were removed on this account, while 4,760 additional cows were regarded as being suspicious. In the milk shed of one of the larger cites, 64,041 cows were examined and 9,027, or 14.1 per cent, were found to have marked physical cases of mastitis. In view of these results it would appear that the percentage of cows in Class 4 found here could hardly be considered abnormally high. If a similar agreement should extend to the other three classifications, then it might be said that roughly 10 per cent of the cows in milk production have normal udders, 25 per cent have reasonably good udders, while 50 per cent show definite evidence of mastitis, and finally 15 per cent or 1 out of every 6.5 animals are no longer suitable for dairy purposes.

That the streptococci are responsible for the larger portion of the indurations found in these udders seems to be clearly demonstrated by this work, but it is also equally evident that even if the streptococci were eliminated a certain amount of mastitis would still be present in the herd. These same facts are also of importance with regard to the value of clinical examination of the udder in the detection of mastitis. Cows which have or have had mastitis, irrespective of the cause, for any ap-

preciable length of time can be detected by this method with remarkable consistency, and in addition this method is extremely useful in selecting animals which should be removed from the herd on account of badly diseased udders.

SUMMARY

Milk samples from 629 cows in 9 dairy herds were examined by 3 bacteriological methods for the presence of streptococci. The 3 methods used were the Hotis test, microscopic examination of incubated milk, and culture of incubated milk on blood agar plates. When streptococci were found on the blood agar plates, they were tested in differential media and placed in groups according to their action on these media.

Streptococci were detected in milk samples from 298, or 47.4 per cent of all animals examined. These animals, however, were present in only 5 herds. No streptococcus infected cows were found in 4 herds with a total of 82 animals. The highest incidence of infection occurred in the largest herds, and the lowest in the smallest of the 5 herds.

Although streptococci were detected in 298 milk samples by the 3 tests, cultures were recovered from 276, or 90.2 per cent. From their action on trehalose and sorbitol, these strains were divided into 3 large groups and further divided into sub-groups on the results on the other media. Seven groups were found. Group A, or *S. agalactiae*, predominated, and when Group G, which differed from it only in the latter's failure to acidify trehalose, is included, formed 83.3 per cent of the cultures isolated. About one-half of the Group G strains fermented trehalose when tested a second time several months later.

The udders of 617 cows were examined by palpation for indurations as

soon as possible after they were milked out. On the basis of physical condition 45, or 7.3 per cent, of the animals were placed in Class 1, or free of indurations; 149, or 24.1 per cent, were in Class 2 with slight indurative changes; 321, or 52.0 per cent, were definitely indurated and placed in Class 3; and 102, or 16.5 per cent, showed marked physical evidence of mastitis, and belonged in Class 4.

There were 291 cows infected with streptococci as compared with 326 in which these organisms could not be detected. Of the infected animals 7, or 2.4 per cent, of the udders were in Class 1, while 38, or 11.6 per cent, of the uninfected cows fell in this group; a difference of about 5 to 1. In Class 2 there were 53, or 18.2 per cent, of infected cows and 96, or 29.4 per cent, of uninfected cows, a ratio of not quite 2 to 1. There was no significant difference in Class 3 between the two groups, but in Class 4 there were 72, or 24.7 per cent, infected cows against 30, or 9.2 per cent, uninfected, or about two and one-half times as many as the former.

An Inexpensive Method for the Dehydration and Preservation of Complement and Other Biological Materials

ENRIQUE E. ECKER, PH.D., AND L. PILLEMER, PH.D.

*Institute of Pathology, Western Reserve University, and
University Hospitals, Cleveland, Ohio*

AS early as 1896, C. J. Martin¹ suggested the possibility and procedure involved in the preservation of guinea pig complement in the dried state. Noguchi,² in 1907, dried complement and amboceptor on filter paper. Shackell,³ in 1909, dried complement in the frozen state and showed that it could be preserved for months. Karsner and Collins,⁴ in 1919, applied Shackell's method for the preservation of various sera and in 1923 Hartley⁵ and his associates reported the dehydration of complement by distilling off the H₂O in vacuo. In 1931, Craigie⁶ dried complement from the frozen state by means of a vacuum desiccator, and more recently Elser⁷ and coworkers showed conclusively that biologicals could be dehydrated from the frozen state. This method was admirably developed by Flosdorf and Mudd⁸ and resulted in their dry-ice "Lyophile Apparatus" by means of which complement may be preserved for several months without any detectable deterioration.

The necessity of an inexpensive and simple method involving only apparatus available in the average laboratory led us to the construction of the following device:

The apparatus consists of a High-vac pump, a gallon size aspirator bottle or suction flask, which serves as a trap, and an ordinary vacuum desiccator. Since the success of the desiccating process depends upon a desiccant of great efficiency, porous (granular) barium oxide was selected.⁹ It takes up moisture with great rapidity and has no measurable vapor pressure and the fact that it cannot be reactivated is offset by its cheapness and availability. Barium oxide does not become sticky and does not channel if the container is properly filled.

THE PROCEDURE

The apparatus is set up in such a manner that the top of the aspirator bottle is connected to the top of the vacuum desiccator by means of a large glass T tube, 1.2-1.5 cm. in diameter, which is connected to a stopcock and manometer. The lower outlet of the aspirator bottle is attached directly to the pump with a heavy walled rubber connection. The bottom of the desiccator is filled with BaO and an equal amount is placed into the trap bottle. Thirty grams of BaO is sufficient to dry 1 c.c. of fresh serum. It is of im-

portance to increase the surface of the BaO by stratification. Cotton layers may be used. The lower outlet of the trap is filled with cotton to protect the pump. After greasing of all connections with stopcock grease, the sera are frozen in a dry ice bath with alcohol, acetone or kerosene. The vials are dried and placed in the desiccator; the pump is immediately started at full capacity to remove all residual air. By the time the frozen serum has reached the fusion temperature, the air pressure is reduced to such an extent that moisture is taken up by the BaO with sufficient rapidity to maintain the serum in the frozen state. Depending on the quantity of materials used, condition of the desiccant, the period of drying varied from 12 to 18 hours. An important point to note is that in the freezing of complement the thickness of the layer should not exceed 12 mm. Slanting and rotating the vials during freezing is a convenient method to increase the evaporating surface. After the first hour the speed of the pump may be reduced.

When drying is completed, the

vacuum is released slowly by way of the stopcock and the vials which contain the dried serum, which is highly hygroscopic, are immediately stoppered with rubber stoppers. For the insertion of the stoppers a small amount of oil (paraffin) may be used. Water should be strictly avoided. The air in the vials is then exhausted through a hypodermic needle attached directly to the High-vac pump. Five minutes suffice to secure vacuum sealing of the vials. Finally, the rubber stoppers are dipped in molten paraffin.

The method has proved to be effective in the drying of virus containing materials and other substances like human milk.

Tennessee Opens Health Unit Building

A NEW building for the Gibson County health unit, at Trenton, Tenn., was dedicated recently. This building, erected and equipped at a cost of \$40,000, was built with the aid of the Commonwealth Fund.

The speakers at the dedication cere-

monies included Barry C. Smith, Executive Chairman of the Commonwealth Fund, and Wilson C. Williams, M.D., Tennessee State Health Officer.

Earl P. Bowerman, M.D., is at present Acting Director of this unit, succeeding Frank L. Roberts, M.D.

Educational Qualifications of Sub-Professional Field Personnel in Sanitation*

IN small health units where each of the persons engaged in environmental sanitation must of necessity cover a wide range, the individuals employed should in all cases meet the qualifications set forth for public health engineers or sanitarians. In the larger city and county health agencies having divisions of general, food, milk, and industrial sanitation, the direction of these various branches should likewise be by individuals meeting the qualifications set forth for public health engineers or sanitarians. It is realized that it may be necessary or desirable to employ or to continue to employ non-professional personnel in subordinate positions in the larger city and county health agencies until such time as public health adminis-

trators are able to require the higher standards prescribed for the public health engineer and sanitarian grades. The committee recommends:

1. That such sub-professional personnel be given the title of Sanitarian Assistant rather than the title of Sanitary Inspector, Sanitary Officer, or Sanitation Officer.

2. That the education and experience requirements be not less than graduation from high school, and at least 2 years' experience in some line of work that has brought the individual in contact with the general public.

3. That all sub-professional personnel be given in-service training, supplemented by such short course training as may promote proficiency in performing the duties assigned. The aim of these courses should be the equivalent of a 2 year college course.

Graduation from high school or its equivalent and completion of a 2 year course in an institution providing a course of instruction in public health prior to employment is considered the equivalent of 2 and 3.

4. That persons of this sub-professional group not having had instruction or experience in health work should not have passed their 35th birthday at the time of first employment.

W. S. LEATHERS, *Chairman*

* The Committee on Professional Education of the American Public Health Association publishes this progress report to permit the members and Fellows of the American Public Health Association to review it and to offer criticisms and suggestions to the committee in the further consideration of the report.

THE SIXTY-SEVENTH ANNUAL MEETING

IT is not news to the members of the Association that every year for 66 years a convention has been held which from the earliest days to the present has engaged the attention, thought, and active participation of the best minds in the public health movement. Each year has seen the high-water mark advanced a little. Each year has recorded progress—in research, in technic, in application of scientific principles, in professional solidarity. There have been few Annual Meetings when something has not “broken,” as the gentlemen of the press say. Some of those “breaks” have represented the opening of a door and a sudden heretofore unsuspected vista down which many of us have trooped with enthusiasm and profit. Some still remain the first and last word definitely spoken and accepted.

The keynote of the more recent meetings has seemed to some observers to be that of reviewing, evaluating, checking, appraising, and assimilating. The currently popular phrase “refresher course” might be applied with truth. This is all to the good. One takes a deep breath after a long climb, looks around and back to survey what has been traversed. One also pauses on the levels to take stock of his companions and wait for the less fleet to catch up. The consciousness of ourselves as members of a body or a group comes to us in these lulls and we move on at last, never again so unaware of those beside us, above us, and below. Perhaps the reviewing process commented upon, has been responsible for the burgeoning recognition of ourselves as members of a powerful profession.

We approach the 67th Annual Meeting in Kansas City, Mo., October 25-28, in the strongest position as a profession that we have yet occupied. It is well then, with all that lies in the immediate future for public health workers in the way of the new and the untried, that we have had the opportunity to look back over the route we have come and to extract from our experiences and our awareness of each other fresh courage to attack the new heights. That there are new heights just ahead cannot be questioned. This meeting, coming as it does in a year of most significant happenings which have already put more money into public health budgets than ever before in our country's history and which

may soon release more funds than the most sanguine dreamed of even two years ago, may well mark the "ridge of the hill," to borrow Dr. Parran's vivid expression.

From the Association's standpoint this has been a remarkable year. As a natural result of expanding health services, the membership rolls have extended to an unprecedented length. There are 6,100 names on the roster, more than 1,000 added since the last Annual Meeting. We shall find many new faces at the 67th Annual Meeting. The new minds will help formulate the new philosophies whose beginnings may be traced back in later years to Kansas City in 1938.

FOOD POISONING BY STAPHYLOCOCCI

WITH increasing frequency reports are appearing concerning food poisoning by certain strains of the staphylococcus. Recently two unusually extensive outbreaks have occurred, one in the United States¹ and one in Canada.²

In May, 1936, there was reported to the State Board of Health of Montana an extensive food poisoning in Billings during which at least 54 persons were seriously affected. Investigations pointed very strongly to a single bakery and to cakes which contained a filling made of flour, eggs, water, and sugar. This was prepared in the bakery twice a week and stored in a mechanical refrigerator. The symptoms in almost all cases developed within 4 or 5 hours after eating the food. There was marked abdominal pain, frequent movements of the bowel—in some cases as many as 20—and vomiting, with severe prostration, but fortunately no deaths. The picture was that of an acute intoxication rather than bacterial infection. Fortunately, the original lot of filling for the orange cream cake which seemed to be the offending article could be obtained and was studied at the State Laboratory. Both the *Staphylococcus aureus* and *albus* were recovered and it seemed evident that both strains were associated with the production of the symptoms.

The second outbreak occurred in Hamilton, Ont., March, 1938, with 21 persons reported as having been poisoned. Investigation showed that custard filled pastry was the only article of food eaten in common which could be considered a possible source of illness. Members of the family who had not eaten the pastry were unaffected. In this outbreak the symptoms usually appeared in from 1½ to 2 hours. They were essentially the same as those described in the Montana outbreak. No deaths occurred. *Staphylococcus aureus* was isolated from the incriminated food as well as raw material used in its preparation and from the utensils used. A number of cultures were sent to the Connaught Laboratories where they were studied with great care. The investigation showed that three strains were practically identical in toxin production and that the cultures isolated from the pastry bag in the bakery were identical with those found in the incriminated food. Cultures of staphylococci from the noses and throats of the employees were easily divided into two distinct groups; one of which had properties very similar to those isolated from the suspected food, while the other produced toxin of much less potency. It seemed reasonable to conclude that the source of the infection was one person who had spread his infection to his fellow employees by whom it was further conveyed to raw materials, utensils and the finished food products. The bakery itself was in a sanitary condition and reasonable care in handling the finished products was

exercised. A point worth observing is that the absence of clinical evidence of a nose or throat infection in an employee was no indication that he was not harboring the microorganism.

In the Montana outbreak one history is perhaps particularly interesting. A woman purchased a layer cake on Saturday and ate of it Sunday evening. She was quite ill for several hours with vomiting and purging. Not suspecting the cake, she put a piece in her husband's lunch box which he ate at his midnight lunch. About 4 hours later he vomited 5 or 6 times, felt chilly, had 6 or 8 movements, and was markedly prostrated. Still not suspecting the cake, the following day this woman again put a piece in her husband's lunch box. This was eaten at the second midnight lunch and 3 hours later he had a recurrence of his illness.

Both of these investigations, one of which was very thorough, have demonstrated that fillings such as that described are one of the chief methods of spreading staphylococcus poisoning. Jordan long ago pointed out that staphylococcus was particularly apt to produce poison when grown on starchy medium.

Investigations^{3, 4} on staphylococcic mastitis in cows are important in this connection, since they indicate that this type of mastitis is probably more common than has been believed. Strong evidence of the danger of such infections has been brought forward. Shaughnessy and Grubb, in every outbreak investigated by them, have found cases of staphylococcic mastitis in the herd which supplied the milk. They suggest that the parasitic staphylococci may be more capable of producing an enterotoxin than the saprophytic forms. Here is another argument for the pasteurization of all market milk, though, as in the Hamilton outbreak, it would not have been effective, as the contamination of the food products evidently took place from handlers of the food product.

DIPHTHERIA IMMUNIZATION

IMMUNIZATION against diphtheria has occupied the attention of scientific men for a number of years. Many of our states have been very active in carrying it out and successful campaigns have borne rich fruit. Great advance was made when Ramon invented his toxoid, the so-called anatoxine. Soon, however, it was shown that toxoid precipitated with alum gave a preparation which was very efficient and that a high degree of immunity could be obtained with a single injection, a tremendous advantage in carrying out immunization on a large scale. In this country perhaps alum precipitated toxoid is still more largely used than any other preparation and is producing good results.

France has lately (June 25, 1938) put the official stamp of approval on immunization against diphtheria, making it compulsory for all children during infancy, that is, in the second or third year of life. The actual law is as follows¹:

"Antidiphtheria vaccination with l'anatoxine (toxoid) is compulsory during the second or third year of life. The parents or guardians are personally responsible for the carrying out of this measure, proof of which shall be furnished on admission to any school, nursery, vacation colony, or other assembly of children.

During the first year of application of the present article, all children under 14 years of age attending the schools, if they have not yet been vaccinated against diphtheria, shall be subjected to such vaccination.

A public administrative regulation, rendered according to the opinion of the Academy of Medicine and the Consultative Committee on Public Health of France, shall decide the measures necessitated by the application of the preceding provisions."

BOOKS AND REPORTS

Life, Heat, and Altitude: Physiological Effects of Hot Climates and Great Heights—By *David Bruce Dill*. Cambridge, Mass.: *Harvard University Press*, 1938. 211 pp., 27 tables, 25 figs. Price, \$2.50.

In the style of swing music, this book presents a succession of variations on the basic theme that every animal physiologic function depends upon the supply of oxygen. Temperature regulation and the rôle of sweat therein; thirst of fish, frog, man, and dog; the breath and the blood of Clarence DeMar or of the Peruvian llama; the reason for prostrations in the early heat waves of our summer; the psychological condition of the crew of a China Clipper in flight to Hong Kong and back, all are shown to possess a common denominator in their relation to oxygen transport by erythrocyte, serum, and lymph, where electrolytes, ions, and water are shifted according to rule and to suit the occasion. Here is no trite recitation of orthodox dogma, but rather a vigorous presentation of personal convictions with supporting evidence, based to a refreshing degree upon the original work of a group of collaborators of the Fatigue Laboratory at Harvard who performed tests upon each other while themselves under stress of desert heat or the anoxemia of altitude, who found time and interest to study the animals they could collect about them in strange places.

Arranged for a series of Lowell Lectures, the material is presumed to be addressed to the non-technically trained, and to any thoughtful reader will be informative. Its appeal to the biologist who is accustomed to the

language and the symbols of experimental physiology is assured. The feeling of the reviewer upon reading the volume from cover to cover is that here is physiological literature fresh, reliable, attractive, compounded of virtuosity and convincingness.

Besides technical interest for aviators, travellers, mountain climbers, physicians, physiologists, and biochemists, there is here much of fundamental importance for the student of personal or public hygiene.

JOHN W. M. BUNKER

The Public Assistance Worker—*Edited by Russell H. Kurtz*. New York: *Russell Sage Foundation*, 1938. 224 pp. Price, \$1.00.

This compact volume is as comprehensive a survey of the public assistance field as has yet been written.

In the first chapter Arthur Dunham outlines the development of relief agencies in America and the problems that they face. Donald S. Howard next explains what requirements an applicant for relief must meet and what are the long-time results of his having to do so. Margaret E. Rich continues the discussion of how people are affected by receiving relief, indicating what reaction they may have to the procedures involved in applying for the various types of assistance. Dora Goldstine takes up the problem of maintaining the health of people receiving assistance, pointing out that the adequacy of the aid given has a great deal to do with the physical condition of the recipients and that the social worker can do much to lift the general level of physical well-being among those she comes in contact with if she

knows the danger signals of ill health and the resources there are to call upon.

In conclusion, Gertrude Vaile discusses the relationship of the public assistance worker to her community and Russell H. Kurtz has a chapter on her relationship to the profession of social work.

CATHERINE GROVES PEELE

Practical Physiological Chemistry
—By Philip B. Hawk and Olaf Bergeim (11th ed.). Philadelphia: Blakiston, 1937. 968 pp. Price, \$8.00.

To those unacquainted with this standard work, it may be described as a comprehensive system of biochemical methods interwoven with an interpretive text of principles and facts. It is a veritable storehouse of procedures which maximizes the practical side; yet, through the enviable economy of words its factual content covers the entire field, and in fundamentals achieves exceeding completeness. That was its original design: even now in the eleventh edition it remains unchanged. Since its first appearance this book, while expanding, has been able to accommodate within its original framework the onrush of new topics from the almost cataclysmic developments in the biochemical world. That it has passed through 10 editions in 30 years, retaining its best features to be combined with new material, attests the soundness of this plan.

Truly the task of surveying the ever widening biochemical domain has become herculean; hence, the participation of two collaborators in the preparation of this edition is not unexpected. In it, 12 chapters have been rewritten. Enlisted for certain of them were the services of specialists who have treated their topics with a sureness of one who has been over the ground. The latest techniques are explained in detail and every selection draws upon the experi-

ence of these qualified investigators. It is through its accuracy and reliability that a method earns its claim to consideration. On these points even critical judgment and discriminatory powers cannot substitute for a working knowledge of a particular method.

In all essentials the book maintains its previous high standards. Its detailed methodology, its concise informative text, and its well selected bibliography still assure it what it has held for so long, an important place in bench-side biochemistry.

H. D. KRUSE

The Chemical Analyses of Foods and Food Products—By M. B. Jacobs. New York: Van Nostrand, 1938. 487 pp. Price, \$6.00.

The book is a systematic presentation of methods of chemical analyses of foods and food products. The details of methods are supplemented by 65 useful tables and 56 figures.

Following introductory chapters on general methods of analysis are chapters dealing with coloring matters, preservatives and metals in foods and then more detailed methods as applied to milk products, oils and fats, sugars and carbohydrates, and gums, cereals, starch and other polysaccharides. Further chapters deal with jams, jellies, and fruits; spices, flavors and condiments; non-alcoholic beverages; alcoholic beverages; meat, fish, and eggs, and vitamins.

The author has presented short practical methods which are of importance in routine analyses of foods. The methods are up-to-date and well presented and much of the information deals with newer methods difficult for the average worker to obtain otherwise.

The book should be a valuable addition to the library of any food chemist or technologist or any other worker dealing with foods. It should also be helpful as a reference volume or text-

book in teaching or in routine analytical and control laboratories.

CARL S. PEDERSON

Handbook on Social Hygiene—
By W. Bayard Long, M.D., and Jacob A. Goldberg, Ph.D. Philadelphia: Lea & Febiger, 1938. 442 pp. Price, \$4.00.

Here is a timely and authoritative symposium. It furnishes 442 pages of technical guidance and basic philosophy in social hygiene—that field where problems relating to sex are given an airing. It should prove particularly helpful to sanitarians, especially to those among the state, city, and county health officers who have heard and participated in sporadic discussions on “lues” and “Neisserian infections” for many years, but who have accomplished little in the control of syphilis and gonorrhea.

The past 2 years have witnessed the renaissance of efforts designed to control and eventually eliminate the venereal diseases. With the recent passage of the LaFollette-Bulwinkle Bill, the U. S. Public Health Service is in a better position to implement the nation-wide campaign, but, as the editors say, “Limitations of our present medical and institutional facilities; drawbacks of the available drugs, and shortcomings of current chemotherapy; lapses in diagnostic tests and the need for their improvement—these and many other problems are still to be faced from the point of view of diagnosis and treatment.”

Far more space than is allotted for this review would be required to evaluate the volume adequately. Therefore the reviewer takes refuge in listing the section headings and authors and letting them tell their own stories:

“The Campaign Against Syphilis and Gonorrhea,” by William F. Snow, M.D.; “History and Cutaneous Manifestations of Syphilis,” by Howard Fox, M.D., Sc.D.;

“The Diagnosis of Syphilis,” by W. Bayard Long, M.D.; “The Treatment of Syphilis,” by Dr. Long; “Syphilis of the Nervous System,” by I. S. Wechsler, M.D.; “The Medical Aspects of Syphilis,” by I. Ogden Woodruff, M.D.; “Syphilis and Gonorrhea of the Eye,” by Conrad Berens, M.D.; “Prenatal and Congenital Syphilis,” by W. Bayard Long, M.D.; “Gonorrhea in the Male,” by Howard S. Jeck, M.D.; “Gonorrhea in the Female,” by Emily Dunning Barringer, M.D.; “Vaginitis,” by Reuel A. Benson, M.D.; “Laboratory Aspects of the Venereal Diseases,” by John F. Mahoney, M.D.; “Hospitals and Out-Patient Clinics—Their Organizations and Management in Relation to the Venereal Diseases,” by Claude W. Munger, M.D.; “Department of Health Programs for Combating Syphilis and Gonorrhea,” by Charles W. Clarke, M.D.; “Statistics Relating to Syphilis and Gonorrhea,” by Jacob A. Goldberg, Ph.D.; “Social Service and Epidemiology Relating to Venereal Diseases,” by Rosamond W. Goldberg, R.N., Ph.D.; “The Responsibility of Nursing Schools in the Control of Syphilis and Gonorrhea,” by Anna D. Wolff, R.N.

“The Public Health Nurses and Syphilis Control,” by Amelia H. Grant, R.N.; “The Problems of Syphilis and Gonorrhea in Family Welfare Agencies,” by Alta E. Dines, R.N.; “Social Hygiene Education in Relation to Venereal Disease Control,” by Maurice A. Bigelow, Ph.D., Sc.D.; and “Legal Aspects of the Venereal Diseases,” by Jacob A. Goldberg, Ph.D.

RAY H. EVERETT

Syphilis, Gonorrhea, and the Public Health—
By Nels A. Nelson and Gladys L. Crain. New York: Macmillan, 1938. 360 pp. Price, \$3.00.

The authors of this book are to be congratulated upon the success with which they have solved the many problems which must have arisen in presenting the salient facts concerning the natural history and control of these two diseases to the diverse groups which are, or should be, interested. The book is written for “health officers, physicians, nurses, social workers, and public health workers in general, as well as that part of the general public which is interested in the control program.”

The three main divisions will appeal to different groups of readers, but each is comprehensive and authoritative enough to justify getting the book for its sake alone. The first main division (Part II) outlines for syphilis and gonorrhea separately the basic facts about the causative agents, course of infection, diagnosis, treatment—including unfavorable reactions to treatment—and modes of infection. It is unfortunate that a more definite position could not have been taken on the treatment of gonococcal infections with sulfanilamide at the time this section was written, but the authors have at least taken a conservative stand in awaiting the verdict of more extensive trial. The discussion of the clinical aspects uses technical terms, but these are explained in sufficient detail so that laymen should have little difficulty. Medical readers also will find these chapters highly informative.

The second main division (Part III) consists of a review of the somewhat fragmentary knowledge of the general epidemiology of gonorrhea and syphilis, each item being presented with due regard for its limitations.

The third main division (Parts IV and V) is the most significant for the public health worker, for it discusses control programs and the problems encountered in their formulation and application. Few Gordian knots are cut but the authors do not fail to offer practical approaches to the solution of questions confronting both state and local health workers, including methods of reporting, case finding and case control, the provision of laboratory, therapeutic, and consultation services, education of the various groups chiefly concerned, the relative duties of nurses and of social workers, financing, and the relationship of social hygiene to the control program.

It does not detract from the value of this book to say that the discussion

is largely from the point of view of the control program as developed by the Massachusetts Department of Public Health, for that state has an advanced program—thanks in no small degree to the senior author. In its broad outlines the Massachusetts program accepts the measures recommended by the U. S. Public Health Service for state and local health departments in January, 1936.¹ However, there are a number of respects in which it is definitely at variance with current practice elsewhere and with the recommendations expressed or implied. Among these are the inclusion of gonorrhea with syphilis on an active basis in the control program, and the fact that legislation "against" the disease is kept at a minimum. The authors cite conflicting viewpoints and give their opinions, which are cogently expressed.

The volume draws from the experience of a decade of earnest and thoughtful work in the field of the genitoinfectious diseases and should be widely read.

1. Vonderlehr, R. A., et al. Recommendations for a Venereal Disease Control Program in State and Local Health Departments. *V. D. Inf.*, 17, 1:1 16 (Jan.), 1936.

RALPH E. WHEELER

Nutrition of the Infant and Child
—By Julian D. Boyd, M.D. New York: National Medical Book Co., 1937. 198 pp. Price, \$3.00.

This monograph should prove helpful to the medical student and general practitioners of medicine. The pediatric specialist will find very little new material in it. The book apparently was not conceived for the lay reader. After the fundamental considerations of food requirements are stated, considerable attention is given to departures from normal nutrition. The chapters on breast and artificial feeding are very practical. The illustrations deal largely with pathologic conditions due to malnutrition, undernutrition, and avita-

minoses. Practical methods of handling the infant for various therapeutic measures are well described and illustrated. Helpful tables and diet schedules for the normal and the sick infant are given at the end.

RICHARD A. BOLT

Child Guidance Procedures: Methods and Techniques Employed at the Institute for Juvenile Research — *The Century Psychology Series*. By the Staff of the Institute for Juvenile Research, Chicago, Paul L. Schroeder, M.D., Director. New York: Appleton-Century, 1937. 362 pp. Price, \$2.50.

The Institute for Juvenile Research, in a quite definite sense, may be looked upon as the parent organization in the field of child guidance clinics. From it also have come some notable studies particularly in the fields of sociology, psychology, and psychiatry which amply justify the authors in looking upon the institute as a research center. It has served as a training center, though its chief purpose has been service to those brought to its attention.

This well written and well edited book aims to make explicit the procedures in child guidance as practised in the institute. There are chapters devoted to the Social History, The Medical Study, the Psychological Examination, The Psychiatric Interview—the so-called fourfold approach to the problem—and also a chapter entitled The Recreation Study. In the majority of clinics the latter is not assigned to special workers, and we see no particular reason for separating it as a special procedure. A good deal of the material investigated would quite naturally fall to the lot of social worker and, in particular, psychiatrist. In fact, one could well raise the question—and the authors hint at it—Whether this division into 4 or more parts at the hands of as many individuals of dif-

ferent and diverse training is either so valuable or so necessary. There has been a growing tendency in many clinics to ignore the so-called fourfold approach and to center the study and treatment in one or another of the staff, depending on the nature of the problem presented. Clinics may vary markedly in their intake policy, which in turn would affect the nature of the study. Those clinics which can control their intake policy and in which psychiatry is emphasized—not sociology—will deal with neurotic children to a much greater degree than with social delinquents, and the approach will of necessity be different.

There is an interesting chapter entitled, Synthesis and Program of Therapy, in which appears an Outline of Psychotherapy and Other Aids in Adjustment. In it are outlined various procedures and technics that may be employed by the psychiatrist in treatment.

The illustrative cases, as is usual, do not clearly illustrate, though they do show what can be done, often under adverse conditions.

The chapter, The Clinic and the Community, Table I, shows what we feel to be a desirable trend, namely the acceptance in recent years of many more cases referred by parents and schools and less from the social agencies. This points to the institute's increasing interest in the neurotic child and a more definitely psychiatric approach to the problems.

The book quite adequately presents what the title indicates—child guidance procedures. It undoubtedly will serve to give the reader not trained in a child guidance clinic an idea of the procedures, methods, and ideology of the average clinic. We recommend it to health officers, administrators and, in particular, those dealing with child Welfare.

HENRY C. SCHUMACHER

Graphs: How To Make and Use Them—By *Herbert Arkin and Raymond R. Colton*. New York: Harper, 1936. 224 pp. Price, \$3.00.

This book should be on bookshelves next to "Statistical Methods" by the same authors. It is the first book on graphs in which we have seen all of the "tricks of the trade" listed.

The first three chapters are devoted to principles, construction, and equipment, in which are set forth the various kinds of paper, pens, inks, and lettering guides. Separate chapters are devoted to the different types of charts where in each case may be found a list of common errors to avoid. The authors cite rules for titles and footnotes which if followed would take the curse off many charts. They also stress the point that charts should be simple and should tell one story, not many. Chapters are also given to reproduction of graphs and the preparation of statistical tables and reports. There is also a complete index.

The entire book is written in the simple straightforward style that made *Statistical Methods* so valuable.

While it does not confine itself to the presentation of public health statistics all of the material is applicable to this field and it will be of great assistance to anyone interested in or concerned with modern graphic presentation of public health statistics for both the lay public and the professional groups.

E. J. CROSS

How To Live—By *Irving Fisher, LL.D., and Haven Emerson, M.D.* (20th ed.) New York and London: Funk and Wagnalls, 1938. 422 pp. Price, \$2.50.

A book which has reached its 20th edition and the worth of which has been recognized in every part of the United States, does not call for a review—only an announcement of a new edition. However, this last volume

sees Dr. Haven Emerson as co-author with Professor Irving Fisher in place of the late Dr. Eugene Lyman Fisk, who was associated with Professor Fisher in getting out the earlier editions, and to whose memory the book is now dedicated.

This edition has followed the earlier ones in bringing the subject matter up to date and in presenting the most recent authoritative conclusions on each subject discussed. The authors regard the book as unique and even radical in its recommendations, but properly hold that it is based on the work of conservative advisers and hope that they are just a little ahead of the world, which will eventually catch up with them.

A striking feature is the 32 appendices, each by a specialist in his field. These appendices constitute approximately two-thirds of the volume. A good index adds to the value. It should be noted that the royalties from the sale of this book will be donated to meet the expense of the Vitality Records Office through which valuable information is being collected as to the influence of habits on health.

It can be recommended without reserve. It will unquestionably maintain the high place in the regard of the public earned in the past.

MAZÛCK P. RAVENEL

The Radiology of Pulmonary Tuberculosis—By *J. E. Bammern, M.B., Ch.B., D.M.R.E.* Baltimore, Md.: Wood, 1937. 156 pp. Price, \$4.50.

This is an excellent synopsis of the subject. To those in public health work who desire to refresh themselves concerning the pathology of the lungs as revealed by X-ray, it should be of inestimable help.

There is a good chapter on the physical examination of the chest and the clinical aspects of pulmonary tuberculosis. The illustrations are adequate

and a good bibliography is provided.

It is recommended to those who use X-ray in case finding.

HARRY E. UNGERLEIDER

Bulletin of the Health Organisation of the League of Nations—Geneva. Vol. VI, No. 4, August, 1937, 177 pp.

This bulletin is devoted to two subjects and contains a large amount of valuable information. Both subjects are important and timely. The first deals with the Hygiene of Housing; and the second, with Physique and Health. An extensive bibliography is given at the end of each presentation.

The discussion of the Hygiene of Housing is divided into three parts. The first deals with the report of the Housing Commission of the League and tells briefly of the work done by the various Committees on the Hygiene of Housing in the United States, France, the Netherlands, Poland, the United Kingdom, Sweden, and Czechoslovakia.

The second part deals with the report of the Housing Commission of the League and its associated experts, on the Hygiene of Environmental Conditions in the Dwelling. Among the items discussed are: factors influencing bodily heat exchanges and comfort; sensation of warmth; optimum environmental conditions; methods of measuring environmental conditions; transmission and accumulation of heat by building materials; heating; cooling; ventilation; air conditioning; and program of studies: coöperation, and teaching.

The third part deals with the report on Noise and Housing which was made by the same Commission and a special group of experts.

The second subject treated in the *Bulletin* deals comprehensively with Physique and Health. The report represents the results of a series of in-

quiries into the physiology, anthropometry, pathology, physical activity, and education of human beings throughout the life span. In the words of the author, "after successfully tackling epidemiology and the environment of life, hygiene is turning its attention to man viewed as a whole." Each phase of life, from the prenatal stage and infancy to old age, comes in for special consideration. The basic data have been obtained from studies made in Austria, Great Britain, Czechoslovakia, Denmark, France, Germany, and Poland. Data from investigations conducted in the United States are also cited. To those who are interested in the growth of children, their physical defects, and their hygienic treatment, including provision for physical exercise and play, the report should prove of great interest and value.

MURRAY P. HORWOOD

The Diagnosis of Syphilis by the General Practitioner—By Joseph Earle Moore, M.D. U. S. Public Health Service pamphlet (originally Supplement No. 5 to Venereal Disease Information). Washington: U. S. Gov. Print. Off., 1938. 36 pp. Price, \$.10.

Because case finding is basic in the stamping out of syphilis and because medical practitioners have the best opportunities for case finding, the means by which the practitioner can more readily suspect and more accurately diagnose suspected cases are given in this compact outline of diagnosis. Diagnostic maxims and lists of conditions with which syphilis should be considered in differential diagnosis are given in tabular form. The sole emphasis is not, however, upon diagnosis as a means of case finding. Contact follow-up is urged as a no less vital aspect of case finding and "the unavoidable responsibility of every physician who makes the diagnosis of early syphilis."

RALPH E. WHEELER

Sewerage and Sewage Treatment
—By *W. A. Hardenbergh*. Scranton,
Pa.: *International Text Book Co.*,
1936. 396 pp. Price, \$3.50.

This is an elementary textbook which covers the field in 24 chapters.

Hydraulics of sewers	24 pp.
Pipe sewers	28
Sewers built in place	11
Sewer appurtenances	20
Miscellaneous features of sewerage systems	13
Planning of sewerage systems	13
Design of sanitary sewers	32
Design of storm and combined sewers	30
Pumping of sewage	11
Construction of sewers	17
Records and estimates	14
Fundamentals of sewage treatment	17
Dilution and irrigation	5
Grit removal and screening	14
Sedimentation	30
Chemical treatment of sewage	15
Activated sludge treatment	11
Secondary treatment of sewage	29
Treatment and disposal of sludge	7
Disinfection	6
Industrial wastes	3
Institutional waste treatment	17
Operation of sewage treatment plants	4

The preface states that the book is intended to present a balanced and basic treatment of the subject for the student and also a text for the engineer who is confronted only occasionally with problems in this field. As a first reader in the sewerage and sewage treatment field, the book is well written and of use to those who are not familiar with the more detailed textbooks. Its value would certainly seem to be impaired by the omission of references, except to ASTM standards. The discussion of sewerage is excellent. In general, the material is up-to-date and illustrates recent practice. For health officers, non-technical sewage works operators, and laymen who want general information, the book should be of value.

A few errors were noted. In discussing the activated sludge process,

the author states that many kinds of air diffusers have been tried, but those made from ground quartz have generally been found most suitable. However, in the last 10 years carborundum and alundum have proved equally acceptable. The author also states that "the plates are usually set in cement mortar in order to prevent clogging around the edges." The real reason for the mortar is to hold the plates in place.

The design of final sedimentation tanks for activated sludge is summed up in 6 lines, saying the same general principles apply as in the case of sedimentation tanks in other processes. Practice has, however, shown a wide difference in design of settling tanks for handling raw or chemically coagulated sewage and activated sludge.

The treatment of the subject of sludge disposal is rather summarily handled. The disposal of air-dried sludge for fertilizer might have been mentioned, as at Baltimore, Rochester (N. Y.), and many other cities. In dewatering digested sludge on a vacuum filter the use of lime as a conditioning agent should have been included. Elutriation, though mentioned, should be noted as of value chiefly only on digested sludge.

In discussing chlorination, the author revives an outworn belief that bleaching powder has the advantage "that the chlorine contained in it is more effective for sewage chlorination than is liquid chlorine."

LANGDON PEARSE

Jurisprudence for Nurses: Legal Knowledge Bearing Upon Acts and Relationships Involved in the Practice of Nursing — By *Carl Scheffel, Ph.B., M.D., LL.B., and Eleanor McGarvah, R.N.* (2nd ed.). New York: *Lakeside Publishing Co.*, 1938. 248 pp. Price, \$3.00.

The second edition of this text, first

issued in 1931, has been broadened somewhat to include new material on the legal standards of the nursing profession. Like the first edition, it also presents useful information on legal obligations of nurses, contracts, wills, the nurse as witness, criminal re-

sponsibility, and property rights. It should be helpful to nurses in the prevention of personal litigation, which in this legalistic era seems to be an achievement almost as salutary as the prevention and alleviation of disease.

JAMES A. TOBEY

BOOKS RECEIVED

THE TECHNIQUE OF CONTRACEPTION—AN OUTLINE. By Eric M. Matsner, M.D., and Frederick C. Holden, M.D. 4th ed. New York: National Medical Council on Birth Control, 1938. 50 pp. \$5.00.

THE TROUBLED MIND—A STUDY OF NERVOUS AND MENTAL ILLNESSES. By C. S. Bluemel. Baltimore: Williams & Wilkins, 1938. 520 pp. Price, \$3.00.

WATER SUPPLY AND SEWERAGE. By Ernest W. Steel, C.E. New York: McGraw-Hill, 1938. 653 pp. Price, \$5.00.

PHYSICAL AND HEALTH EDUCATION—PRINCIPLES AND PROCEDURES. By Helen Norman Smith and Helen Leslie Coops, Ph.D. New York: American Book Co., 1938. 323 pp. Price, \$2.25.

OSLER'S PRINCIPLES AND PRACTICE OF MEDICINE. Originally by Sir William Osler, M.D. Revised by Henry A. Christian, M.D., LL.D. 13th ed. New York: Appleton-Century, 1938. 1424 pp. Price, \$9.00.

POISONING THE PUBLIC. By Russell C. Erb. Philadelphia: Dorrance & Co., 1937. 219 pp. Price, \$2.00.

ADVENTURES IN SELF-DISCOVERY. By David Seabury. New York: McGraw-Hill, 1938. 324 pp. Price, \$2.50.

PENNY MARSH. PUBLIC HEALTH NURSE. By Dorothy Deming. New York: Dodd, Mead, 1938. 266 pp. Price, \$2.00.

AN INTRODUCTION TO MEDICAL STATISTICS.

By Hilda M. Woods and William T. Russell. London: King & Son, 1936. 125 pp. Price, \$2.75.

THE NEW BABY. By Evelyn S. Bell and Elizabeth Faragoh. Philadelphia: Lippincott, 1938. Price, \$1.00.

SOCIAL WELFARE LAWS OF THE FORTY-EIGHT STATES. Compiled by Wendell Huston. Seattle: Wendell Huston Co., 1937. Loose Leaf Form. 1400 pp. Price, \$12.50.

THE LABORATORY. Vol. 9, No. 5. Published by the Fisher Scientific Co., Pittsburgh. 16 pp. Free.

YOUR BABY AND CHILD. By M. C. Overton. Lubbock, Tex.: Your Baby and Child Pub. Co., 1936. 224 pp. Price, \$2.00.

ADVENTURES IN LIVING SERIES. NEW WAYS FOR OLD. By Thomas D. Wood, Marion O. Lerrigo and Nina B. Lamkin. New York: Nelson, 1938. 320 pp. Price, \$.88.

A TEXTBOOK OF PATHOLOGY. For Use in Schools of Nursing. By Armin V. St. George. 2nd ed. New York: Macmillan, 1938. 238 pp. Price, \$1.75.

TEXTBOOK OF ANATOMY AND PHYSIOLOGY. By Diana Clifford Kimber, Carolyn E. Gray, and Caroline E. Stackpole. 10th ed. rev. New York: Macmillan, 1938. 643 pp. Price, \$3.00.

BABIES ARE HUMAN BEINGS. By C. Anderson Aldrich and Mary M. Aldrich. New York: Macmillan, 1938. 128 pp. Price, \$1.75.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

France Goes After Diphtheria— Translation of the French law requiring immunization of all children during infancy or the second or third year of life.

ANON. Diphtheria Immunization Made Compulsory in France. Pub. Health Rep. 53, 30:1301 (July 29), 1938.

Diphtheria Prevention—New England and Middle Atlantic cities report a continuing downward trend in diphtheria, as do the western cities. Elsewhere the record is not quite so good. There is evidence that the preventive program produces results.

ANON. Diphtheria Mortality in Large Cities of the United States in 1937. J.A.M.A. 111, 6:524 (Aug. 6), 1938.

Where Diets Are Deficient— Calcium lactate in half-grain daily doses accelerated growth and improved the condition of poorly nourished nursery children. Teachers thought it helped the mental performance of the children too. It is recommended as a partial milk substitute when fresh milk cannot be supplied.

AKROYD, W. R., and KRISHNAN, B. G. Effect of Calcium Lactate on Children in a Nursery School. Lancet. 2, 3:153 (July 16), 1938.

How They Die of Rabies— First-hand observations upon a dozen persons as they died of rabies: with pictures! These might be useful for health educators who have to meet antivivisectionists on their home grounds.

BLATT, M. L., *et al.* Rabies. J.A.M.A. 111, 8:688 (Aug. 20), 1938.

Catching Up with the Migrant— For the hundreds of thousands who migrate to California seeking jobs, the

state health service furnishes maternal and infant hygiene, tuberculosis case finding, public health nursing and education in nutrition. What the wanderers seem to need most is education in hygienic living. Administrators will want to know just what this state is doing, hence the report is most timely.

DICKIE, W. M. Health of the Migrant. J.A.M.A. 111, 9:763 (Aug. 27), 1938.

Hitler Jugend and T.B.—In Germany, where everyone presumably is under the control of the State, tuberculosis prevention should be a really productive enterprise, but it seems that it suffers from much the same faults as the program in this country where individualism—rugged or ragged—reserves to each the right to enjoy his infection unmolested.

EDWARDS, H. R. Tuberculosis Control in Germany. Am. Rev. Tuberc. 38, 1:115 (July), 1938.

Brucella Infections and the Lab.—Evidence is presented indicating that no single test can be relied upon to give unfailing proof of chronic brucellosis. High agglutination titres are of significance, a positive skin test is suggestive, and an opsonic reaction is found least reliable. Some brucella infections are negative to all three tests.

EVANS, A. C., *et al.* Studies on Chronic Brucellosis. Pub. Health Rep. 53, 34:1507 (Aug. 26), 1938.

Measles in a School Community—In an epidemic of measles in a boarding school, healthy susceptible children should be allowed to have a normal attack of the disease, while "delicate" susceptibles should be partially or completely protected with immune serum.

How the epidemic was treated in one British institution is told.

HOBSON, F. G. Measles. The Conduct of a School Epidemic. *Brit. M. J.* 4046:171 (July 23), 1938.

Protecting British Mothers—Four British papers on prevention of puerperal sepsis cover about the same ground that four similar American papers would traverse. As with us, the way is evident, but the performance totters. American pediatricians will read the series with sympathetic interest.

JOHNSTONE, R. W., *et al.* The Prevention and Control of Puerperal Sepsis. *Brit. M. J.* 4049:331 (Aug. 13), 1938.

It Runs in Families—Siblings of children susceptible to caries had more than twice the incidence of tooth defects that afflicted the brothers and sisters of persons with healthy teeth. The conclusion is justified that familial resemblances in carious conditions exist. No specific explanation is offered.

KLEIN, H., and PALMER, C. E. Studies on Dental Caries. *Pub. Health Rep.* 53, 31:1353 (Aug. 5), 1938.

Of Interest to Pneumonia Campaigners—Reporting the successful use of anti-pneumonia rabbit serum in 6 types of pneumococcus pneumonia. No patients died when treated within 90 hours, and no untoward reactions marred the picture.

LOUGHLIN, E. H., *et al.* The Treatment of Lobar Pneumonia with Rabbit Anti-pneumococcus Serum. *J.A.M.A.* 111, 6:497 (Aug. 6), 1938.

Public Hygiene and Decent Housing—Our duty is clear, concludes this Canadian sanitarian: use every opportunity to bring to public attention the urgent need for play space, and the desirability of one-family dwellings; get solidly behind every effort being made to provide adequate housing facilities.

Would that the duty were equally clear to all sanitarians in the United States!

MACDONALD, R. ST. J. Progress in Housing and Health. *Canad. Pub. Health J.* 29, 8:377 (Aug.), 1938.

Recent Social Hygiene Events—Herein is recounted what state health departments and local official and voluntary agencies are doing in the prevention of syphilis: an impressive total of activities.

PINNEY, J. B., and SHENEHON, E. N. Footnotes to Progress. *J. Social Hyg.* 24, 5-6:245 (May-June), 1938.

Noise—Even though Heaven is alleged to have a select choir and a good loud orchestra, what this earth needs is more quiet, says this British authority on ear-shattering noises by day and sleep-disturbing rackets by night. He discusses the reasons why.

PURVES-STEWART, J. The Influence of Noise on Health. *J. Roy. San. Inst.* 1, 11:667 (Aug.), 1938.

Serving the Worker in Small Industries—Because a very great number of workers are employed, collectively, in plants each too small to provide a health service, there is an effective opportunity here for governmental health administration. How far these needs are being met is told, and a promising program is suggested.

SAYERS, R. R., and BLOOMFIELD, J. J. Public Aspects of Industrial Health. *J.A.M.A.* 111, 8:679 (Aug. 20), 1938.

For Industrial Hygienists—Although there is no one sure method of preventing the pneumoconioses, the conditions causing them may usually be avoided if industrial engineers and physicians will coöperate in adopting measures of known effectiveness.

SAYERS, R. R., and JONES, R. R. Silicosis and Similar Dust Diseases. *Pub. Health Rep.* 53, 33:1453 (Aug. 19), 1938.

ASSOCIATION NEWS

THE TWENTIETH ANNUAL HEALTH EXHIBIT

ALMOST as important as the scientific program at Annual Meetings of the Association is the Health Exhibit which at Kansas City will be celebrating its twentieth anniversary.

The great Exposition Hall of the Municipal Auditorium in Kansas City is the scene of the Twentieth Annual Health Exhibit. Here, on the same floor with Registration and Information Headquarters, Health Education and Publicity Headquarters, the Motion Picture Theatre, the Association and Local Committee offices, more than one hundred commercial and scientific exhibitors will hold forth. The commercial exhibitors have been carefully selected and screened and only those organizations with products of real worth are permitted to engage the attention of the 3,500 delegates. The Health Exhibit, therefore, is a setting for pedigreed products and, as such, they are commended to public health workers for purchase for their departments and institutions and for recommendation to the public.

The exhibitors whose applications for space have been accepted are:

Abbott Laboratories
American Can Company
American Cyanamid & Chemical Corp.
Birds Eye Laboratories
The Borden Company
Carnation Company
The Coca Cola Company
Dermetics Company
Difco Laboratories, Inc.
The Diversey Corporation
Eisele & Company
J. B. Ford Sales Company
Gerber Products Company

Geuder, Paeschke & Frey Company
Gilliland Laboratories
A. J. Griner Company
Hobart Mfg. Company
Horlick's Malted Milk Corp.
Hygeia, The Health Magazine
Holland-Rantos Company, Inc.
Irradiated Evaporated Milk Institute
Kaustine Company, Inc.
Kellogg Company
Kolynos Company
Lea & Febiger
Lederle Laboratories, Inc.
Lily-Tulip Cup Corporation
The Macmillan Company
Metropolitan Life Insurance Co.
Philip Morris & Company, Ltd., Inc.
National Dairy Council
National Live Stock & Meat Board
Pet Milk Sales Corporation
W. B. Saunders Company
The Sealright Company, Inc.
Sealtest, Inc.
E. R. Squibb & Sons
Vitex Laboratories, Inc.
Wallace & Tiernan Company, Inc.
Westinghouse Mfg. Co.

Association members, health departments, national and local agencies are contributing to the technical exhibit a series of timely and important scientific subjects presented graphically. Among the exhibitors in this section are the

U. S. Public Health Service
Hooper Foundation Medical Centre
Kansas City (Kans.) Health Department
Kansas City (Mo.) Health Department
New York City Health Department
Bishop Clarkson Memorial Hospital
Kansas City Health Conservation Association
New York State Department of Health
American Social Hygiene Association
Missouri State Health Department

Nurse Placement Service
National Organization for Public Health
Nursing

Missouri Public Health Association
Kansas City Children's Bureau
American Association of State Registration

Executives

National Association of Sanitariums, Inc.
Jackson County Medical Society
Arkansas State Board of Health
Iowa State Department of Health
The Commonwealth Fund
American School Health Association
International Society of Medical Health

Officers

National Society for the Prevention of
Blindness, Inc.
Yale School of Medicine
University of Pennsylvania School of
Medicine
Queensboro Tuberculosis and Health As-
sociation
National Institute of Health

There is material in the Health Exhibit, under both technical and commercial auspices, well worth careful examination and study. In order to extract the most of value from their attendance at the Annual Meeting, delegates should budget their time, allocating a goodly share of it to the exhibits.

BOOKS AT THE ANNUAL MEETING

THE Association's Book Service will repeat at Kansas City the exhibit of health books of all publishers to which delegates to the Annual Meeting turn for information about the best and newest of the literature of their field.

No one is under any compulsion to buy. Of course, the Book Service is in the book-selling business, and Mrs. Andrus, the Association's Librarian in charge, will gladly hold your coat while you make out your check if you feel the acquisitive urge that overcomes all book-lovers at the sight of a thousand or more volumes stacked on shelves.

Come to the Book Exhibit and examine the books on display. If you read fast you may be able to get

through several of the more absorbing before the meeting is over. Comfortable chairs will be provided. Your free copy of the 1938 *Bibliography of Health Books* will be on hand for you.

INVITATION FROM CHICAGO TO DELEGATES EN ROUTE TO KANSAS CITY

DR. Herman N. Bundesen, President of the Chicago Board of Health, announces that the Chicago Municipal Social Hygiene Clinic has recently moved into new and spacious quarters at 26th Street and Wabash Avenue. He goes on to say "Our facilities there are far better than anything we have had in this line in the past, comprising separate space for diagnosis, treatment, social service, and educational activities. Also the male patients are examined and treated on a different floor from the female cases."

Dr. Bundesen believes that these new facilities may be of considerable interest to health officers, and he invites members and guests of the Association who pass through Chicago at any time, and particularly on their way to and from Kansas City, to visit the Clinic.

NEW MEMBERS OF A.P.H.A. DUE TO WESTERN BRANCH ACTIVITIES

THE Western Branch of the American Public Health Association conducted a membership campaign in the months preceding its last Annual Meeting. Each of the 17 states, territories and provinces comprising the Branch coöperated with the result that the names of over 200 new members were added to the A.P.H.A. membership roster. Top honors went to the State of Utah which had a gain in membership of almost 150 per cent.

Efforts like this have played an important part in bringing the membership of the Association up to the highest point in its history—over 6,200 on September 1.

PROGRAM OF THE INSTITUTE ON THE PRACTICAL ADMINISTRA- TION AFFAIRS OF THE HEALTH OFFICER

SPONSORED by the International Society of Medical Health Officers, for the benefit of all Officials and Public Health Workers Interested in Public Health Administrative Problems.

Kansas City, Mo.—Monday, October 24, 1938

9:30 A.M. Room 401, Auditorium

Presiding: E. L. BISHOP, M.D., President, and LEON BANOV, M.D., Secretary-Treasurer.

The New Appraisal Form for Public Health Work. W. F. WALKER, DR.P.H.

Practical Application of the Appraisal Form. V. L. ELLICOTT, M.D., DR.P.H.

The Place of the Local Health Department in a National Health Program. C. E. WALLER, M.D.

Effective Use of Federal Aid in the Local Public Health Program (With lantern slides). JOHN L. RICE, M.D.

Behavior of Health Jurisdictions with Respect to Employment of Health Officers. JOSEPH W. MOUNTIN, M.D.

Practical Methods of Developing a "Career Service" in Public Health. WILLIAM E. MOSHER, PH.D.

Practical Points in Securing Adequate Appropriations for Health Departments. WALTER N. KIRKMAN.

The Seasonal Emphasis of Various Health Services. J. N. BAKER, M.D.

2:30 P.M. Second Session, Room 401, Auditorium

Practical Problems of Staff Organization. HUNTINGTON WILLIAMS, M.D.

Budgets and Budget Making. J. W. BASS, M.D.

The Annual Report as a Sales Argument for Adequate Appropriations. WILLIAM H. ENNEIS, M.D.

The "How" of Public Health Education. Practical Points on preparing newspaper interviews, radio talks, health meetings, etc. W. W. BAUER, M.D.

Practical Use of Visual Education in Public Health. H. H. WALKER, C.P.H., PH.D.

Selling the Health Department to the Public by Means of Public Health Education. PHILIP S. BROUGHTON.

Practical Record Keeping. W. VAL SANFORD, M.D.

Practical Uses of Vital Statistics. GEORGE H. VAN BUREN.

6:30 P.M. Dinner Session, Continental Room, Hotel Kansas Citian

Presiding: EDWIN H. SCHORER, M.D., DR.P.H. Toastmaster, E. L. BISHOP, M.D.

My Most Humorous Experience as a Health Officer.

My Most Serious Experience as a Health Officer.

My Most Embarrassing Experience as a Health Officer.

My Most Pleasant Experience as a Health Officer.

"Experience" speakers will be selected from the guests. YOU may be called upon for an experience, so please put on your thinking cap.

New Frontiers of Preventive Medicine. FRANK G. BOUDREAU, M.D.

Fraternal Greetings. REGINALD M. ATWATER, M.D.

A closed session for members only, for election of officers and the conduct of general business will be held immediately following the dinner session. Society members are requested to remain.

1938 HEALTH CONSERVATION CONTESTS

THE Committee on Administrative Practice of the American Public Health Association has announced the 1938 Health Conservation Contests for cities and rural areas. This is the 10th year of the project among cities, and the 5th year of the project among full-time rural areas. They continued to grow during 1937, and give promise of expansion both in the United States and in the Dominion of Canada.

In the 1937 Contests the response among Canadian rural units far exceeded expectations, and already additional rural health units are enrolling and planning to submit fact-finding schedules. The Provinces of Prince Edward Island and New Brunswick have signified their intention of being represented in 1938; all the newly organized health units in the Province of Quebec intend to participate; and it is expected that all the 32 Quebec units enrolled for 1937 will again be in the Contest this year.

The Rural Contests both in the United States and Canada were again underwritten by the W. K. Kellogg Foundation of Battle Creek, Mich., while the City Contest in the United States was supported by the contributions of life insurance companies. Most

gratifying is the wider interest of the life insurance groups and the fact that 26 new companies are now listed as financial supporters of the 1938 Contest.

The Committee on Administrative Practice has enlarged and amended the 1938 fact-finding schedules to give a more clearly defined picture of the health activities carried on and the attainments of the different units, thereby aiding the Grading Committee in the ranking of competing units.

Special competitions for syphilis and tuberculosis control activities are again included. This has provided opportunities for areas to secure recognition for outstanding special work. In the 1937 Contest the best showing along these special lines of health activity was made in those places where the public health program along all recognized lines was best developed and rounded.

After another year of almost continuous field contacts with the competing cities and counties, Dr. James Wallace of the Association staff, who is Field Director for the Health Conservation Contests, pointed out that across the continent these Contests continue to provide the *occasion* for initiating new programs and for accentuating and expanding programs already adopted. He

said that the Contests provide the means of uniting many agencies in the health program and, in particular, the business groups through intimate relationships to chambers of commerce and other business agencies. According to Dr. Wallace, the Contests help to standardize health work but primarily aid in individualizing it and in pointing out and achieving the objectives which are of prime importance to the community. "Every participant in these Contests is a winner," said Dr. Wallace, "because the chief award is in the interest awakened, the information disseminated, and the local accomplishments in public health which result."

New Units are currently enrolling from North Dakota, Washington, North Carolina, Ohio, Oregon, Kentucky, Florida, and the Canadian Provinces. Every city in the United States is eligible to participate and every full-time county or district health unit in the Dominion or the United States.

The cities enrolled for the City Contest in 1937 totalled 264 and the Rural Contest included 276 areas, of which 241 were in the United States and 35 in Canada.

SERODIAGNOSTIC TESTS FOR SYPHILIS

THE Assembly of Laboratory Directors and Serologists, to Consider Means and Methods to Improve and Make More Available Serodiagnostic Tests for Syphilis, will be held under the auspices of the Committee on Evaluation of Serodiagnostic Tests for Syphilis, at Hotel Arlington, Hot Springs National Park, Ark., October 21-22, 1938. Thomas Parran, Surgeon General, U. S. Public Health Service, will be Chairman.

The purpose of this Assembly is to permit free discussion of the means and methods to improve and make more generally available serodiagnostic tests for syphilis.

This meeting is being held at the end

of the week preceding the Annual Meeting of the American Public Health Association. It is hoped that laboratory directors and serologists working in public health, hospital and private laboratories from all over the United States will attend.

An invitation is extended to members of the Laboratory Section of the American Public Health Association.

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

WEEK-END hotel reservations at the Elms, Excelsior Springs, Mo., where the Association of Women in Public Health will meet on Sunday, October 23, and Monday, October 24, may be made through the Local Chairman, Miss Rosamond Losh, Children's Bureau, Kansas City, Mo. Single rooms with bath from Saturday afternoon through Monday luncheon \$12.00; two in a room \$9.50 each.

The meeting begins with a tea and informal get-together on Sunday from 4:30 to 6:00. Monday morning an extensive and interesting program is scheduled followed by a luncheon session at 1:00 with addresses by Dr. Frank Boudreau, Dr. Margaret W. Barnard, and Dr. Michael M. Davis. A business session at 3:30 closes the Excelsior Springs events.

At 7:30 Monday evening, a dinner session will be held in the Hotel Muehlebach, Kansas City, to which all are invited.

STATE DIRECTORS OF PUBLIC HEALTH NURSING

A CLOSED meeting for state directors of public health nursing will be held in Room 203 of the Auditorium Monday, October 24, 1938, preceding the annual meeting of the American Public Health Association in Kansas City, Missouri. Hours for the morning session will be 9:00 to 11:00 A.M. The afternoon session will open at 1:00 P.M.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

William E. Alexander, M.D., Memphis, Mo.,
County Health Officer
John M. Allaman, M.D., Central Bldg., St.
Joseph, Mo., Health Officer
Floyd C. Beelman, M.D., 300 S. Broadway,
Wichita, Kans., Sedgwick County Health
Officer
Max E. Blue, M.D., Burkesville, Ky., Cum-
berland County Health Officer
William B. Buckner, M.D., P. O. Box 127,
Albany, Ga., Dougherty County Health
Commissioner
John R. Claussen, M.D., County Court House,
Florence, S. C., County Health Officer
Francis J. Clements, M.D., Stony Creek, Va.,
Sussex County Health Officer
John M. Collins, M.D., State Dept. of Health,
Seattle, Wash., Health Officer Appointee
Robert H. DeJarnette, M.D., Corinth, Miss.,
Director, Alcorn County Health Officer
Edgar A. Dimond, M.D., 300 S Broadway,
Wichita, Kans., Assistant County Health
Officer
Harrison Eilers, M.D., C.P.H., Los Lunas, N.
Mex., District Health Officer
Harry H. Ennis, M.D., C.P.H., District Health
Service No. 1, Le Mars, Ia., Medical
Director
Douglas H. Fryer, M.D., D.P.H., Eutaw, Ala.,
Greene County Health Officer
Elmer E. Gay, M.D., Gay Bldg., Richmond,
Mo., City Health Officer
James H. Gordon, M.D., P. O. Box 747,

HEALTH OFFICERS

Physician, M.D., St. Louis University; post-graduate in eye, ear, nose and throat; 10 years' experience in public health administration as director of county health units and epidemiologist with state department; also experienced in welfare administration, prefers administrative public health position in central or western state. Excellent references. A373

Physician. M.D.. McGill; C.P.H., Johns Hopkins; excellent background of communicable disease control and school health service, seeks position as epidemiologist or public health administrator. A368

Experienced health officer: M.D., Class A medical school; completed Vanderbilt short course for Health Officers, 1936; will consider appointment. A320

Physician, M.D., Class A medical school; M.P.H., Harvard School of Public Health; extensive experience in pediatrics and school medical services; also background of county health administration and teaching in medical school; will consider expanded opportunity in teaching or research. A302

Physician, age 34; M.D., University of Wisconsin; M.P.H., Harvard; specializing in industrial hygiene, will consider general administration. A342

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; now employed, is available as venereal disease control officer. A363

Well qualified physician, with C.P.H. from Johns Hopkins; experienced as school physician and in college teaching, will consider city or county administrative position or teaching and student health service. A383

Physician with Dr.P.H. degree, experienced as a local health officer, in present position since 1929, will consider opening. A386

Physician, A.B., M.D., 30 years in a large city health department. Administrative, educational and research experience; also familiar with venereal disease work. A295

HEALTH EDUCATION

Woman, well qualified in health education, wishes position as health coördinator or health counsellor. Has wide experience, and Ph.D. from New York University. M236

Young woman, M.A., Health Education, Teachers College, Columbia University; with splendid international experience, seeks position as director of health education with preference for New York City. H369

Young man, M.S.P.H., University of Michigan; at present college teacher of hygiene and physical education and experienced in university medical service, desires position as executive in public or private health organization. H357

Woman, M.D., Boston University; special work Columbia and Massachusetts Institute of Technology; 1 year's experience in state hospital; interested in psychiatry, desires position in the East in hospital for mental diseases or industrial school. H247

Young woman, M.S.P.H., University of Michigan, experienced in laboratory research and health education, is available for research or investigative work. H303

LABORATORY

Experienced laboratory director with background of dairy products manufacture and research in control methods; University of Wisconsin, M.S. and Ph.D.; desires administrative position with food manufacturing or processing industry, or association with health department doing routine and research work in food control. L381

Experienced bacteriologist with teaching in research background, seeks position as director of laboratory. L370

Bacteriologist and pathologist with wide administrative experience; Ph.D., Brown University; will consider leading position in his field. L371

Laboratory technician; B.Sc. degree; with experience in Army, state public health laboratory, and U. S. Public Health Service field laboratory, seeks position in medical school or university. L379

Young woman, M.A. in medical bacteriology, University of Wisconsin, 7 years' experience in a state laboratory of hygiene, desires posi-

tion in bacteriological diagnosis, research or a combination of the two. L387

Young woman, A.B., major in bacteriology; 9 years' experience; now employed in a clinical laboratory desires position in bacteriology or serology in a health department laboratory or in research. L382

Bacteriologist, college graduate, special postgraduate work, 9 years' public health laboratory experience in executive, routine and research work, desires to change position. Excellent references. L385

SANITARY ENGINEERING

Public health engineer, B.S. in Sanitary Engineering from Massachusetts Institute of Technology, experienced in Massachusetts, Connecticut and Kentucky, seeks position as sanitary or public health engineer with health department. E380

Experienced sanitary engineer, graduate of Massachusetts Institute of Technology, seeks responsible position. E372

MISCELLANEOUS

Experienced public health nurse executive, Fellow of the A.P.H.A., is available for responsible position. N384

Experienced teacher in bacteriology and public health; Ph.D., Cornell; now professor in Grade A medical school, will consider teaching, executive or administrative position. M327

Physician, graduate of Johns Hopkins Medical School, and well qualified in medicine and tuberculosis, will consider a clinical position in the medical field. M377

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

Woman physician, graduate of University of Iowa, who has directed State bureau of maternal and child health, now employed, will consider another position. C318

NEWS FROM THE FIELD

PUBLIC HEALTH AND SOCIAL SECURITY

THE U. S. Public Health Service, on the third anniversary of the adoption of the Social Security Act by Congress, pointed out the marked increase in public health facilities resulting from funds provided for this purpose.

Under the provision of \$8,000,000 annually for the stimulation of public health activities in state and local governments through the Public Health Service, there were listed the following advances:

The training of 4,300 medical officers, engineers, nurses, sanitation officers, laboratory workers, and others in public health work. An increase from 667 to 1,116 in the number of counties in the country served by full-time public health officers. In 6 states all areas are covered with full-time units, as compared with 3 before the Act became effective. In 24 states there are separate divisions of venereal disease control, in place of 13 three years ago, and the number of states employing a full-time venereal disease control officer has increased from 9 to 30.

Increases were reported from 35 to 44 in the number of states having separate divisions for preventable diseases; from 16 to 31 in the number having divisions for local health administration; from 20 to 32 in the number having divisions for public health nursing; from 3 to 15 in the number specializing in industrial hygiene; from 8 to 17 specializing in dental hygiene; from 16 to 21 in public health education; and from 13 to 17 in tuberculosis control.

It was pointed out that gains also have been recorded in the attention given to cancer control, malaria control, the control of rodent plague, and in

laboratory service. Most of the federal appropriations under the Act for maternal and child health are administered by the Children's Bureau of the Department of Labor.

During the current fiscal year, the funds from the Social Security Act are being allotted for 22 different health activities in the states. For some of these purposes states must match the federal grants on a basis equitably worked out through conferences with the state health officers and the Surgeon General of the U. S. Public Health Service.

VENEREAL DISEASE CONTROL

ALLOTMENTS

THE U. S. Public Health Service has announced that allotments to the states under the Venereal Disease Control Act of 1938 have been made on the basis of population, financial need, and the scope of the venereal disease problems, as provided in the Act. These funds must be supplemented by the States under regulations laid down by the Surgeon General. Of the \$3,000,000 appropriated, \$2,400,000 will be distributed to the states and the remaining \$600,000 will be reserved by the Public Health Service for research and investigation, education and administrative expenses.

OHIO VENEREAL DISEASE PROGRAM

IT is announced, by Walter H. Hartung, M.D., Ohio State Health Director, that the State Health Department is starting a drive against venereal diseases, the program to be financed by state and federal funds. The plan is to expand venereal disease clinics in the larger cities by increasing the number of physicians, technicians, and clerks.

DELAWARE RIVER POLLUTION CONTROL

A RECIPROCAL agreement to correct and control stream pollution within the Delaware River Drainage Basin has been entered into by the 4 states of New York, New Jersey, Pennsylvania, and Delaware. The agreement was prepared under the auspices of the Interstate Commission on the Delaware River Basin and was formally ratified and made operative by the Departments of Health of the 4 states.

Minimum requirements relating to sewage, industrial waste, and other artificial polluting matter have been established. Because of the variable factors of location, size, character, and flow, and the many varied uses of the water of the Delaware River, the stream has been divided into 4 zones and minimum requirements have been drafted to meet the conditions of each zone. No sewage, industrial waste, or other polluting matter may be discharged into the river unless it has been so treated as to produce an effluent which will meet the minimum standards set up by the terms of the agreement.

LEAGUE COMMITTEE ON HEALTH INDICES

A COMMITTEE on Health Indices of the Health Committee of the League of Nations has been appointed to study further the problem of schedules for indices so that the state of health of a given area may more readily be determined.

Reginald M. Atwater, M.D., Executive Secretary of the American Public Health Association, has been appointed a member of the Committee which will meet in Geneva, October 8-11. Other members of the committee include Dr. M. Greenwood, Professor at the London School of Hygiene and Tropical Medicine; Dr. J. Tomcsik, Director of the State Institute of Hygiene, Budapest; Dr. M. Kacprzak, Chief of the Service of Health Statistics, at the State Insti-

tute of Hygiene, Warsaw, and Dr. A. Höjer, Director General of the Health Services of Sweden.

INTERNATIONAL NOMENCLATURE OF DISEASES

THE United States Government has designated representatives to attend the Paris meeting, beginning October 3, of the International Commission for the Decennial Revision of the International Nomenclature of Diseases. George H. Van Buren, Secretary, Jessamine S. Whitney, Dr. Halbert L. Dunn, Thomas J. Duffield, Dr. W. J. V. Deacon, and Dr. George Baehr. The above persons are members of the Sub-Committee on Accuracy of Certified Causes of Death of the American Public Health Association. In addition, Dr. Edwin F. Daily of the Children's Bureau, Selwyn D. Collins, Ph.D., and W. Thurber Fales, Sc.D., have been designated.

PROTEST OF MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

THE Massachusetts Public Health Association has passed a resolution of protest against the report of the National Health Officers Qualifying Board to the United States Conference of Mayors, which was published in the *Journal* for January, 1938, pages 110-111.

The resolution points out that experience in the United States is rich in the demonstrated fact that non-medical health officers as well as medical health officers have administered public health work with outstanding success when they are adequately prepared by training, experience, and personality for the conduct of such work; pointing further to the fact that non-medical scientifically trained public health workers, skilled in engineering, bacteriology, chemistry, physics, sanitation, vital statistics, nutrition, public health education, and other scientific but non-

medical pursuits, have shown administrative ability and success.

The Massachusetts Association records its opposition to the report of the National Health Officers Qualifying Board to the United States Conference of Mayors in so far as the report excludes properly trained and otherwise qualified non-medical public health workers from serving as health officers.

The resolution stipulates that, in so far as this report recognizes the importance of adequate public health training and experience as prerequisites for qualified and efficient public health administrative work, the report has the hearty approval and endorsement of the Massachusetts Public Health Association.

RED CROSS NURSING SERVICES UNDER ONE HEAD

THE various nursing services of the American Red Cross are being unified and Mary Beard, R.N., who since 1924 has been Associate Director of the International Health Division of the Rockefeller Foundation, has been appointed national Director of the Service. Virginia Dunbar, R.N., Assistant Director of the University of California School of Nursing at San Francisco, has been appointed Assistant Director. Both Miss Beard and Miss Dunbar assume their new duties October 1.

Ida F. Butler, R.N., who has been identified with the Red Cross Nursing Service for more than 20 years, and who has been Director of Nursing Enrollment since 1936, retires from active service this fall.

LESLIE DANA MEDAL

THE National Society for the Prevention of Blindness has announced that the Leslie Dana Gold Medal, awarded annually for outstanding achievements in the prevention of blindness and the conservation of vision, has been presented this year to Dr. Ellice

M. Alger, Professor of Ophthalmology and hospital surgeon at the New York Post Graduate Medical School.

NEW YORK SOCIETY OF TROPICAL MEDICINE

DR. Philip Manson-Bahr, Lecturer at the London School of Hygiene and Tropical Medicine and Physician to the Hospital for Tropical Diseases, Endsleigh Gardens, London, was guest speaker at a meeting of the New York Society of Tropical Medicine, at the New York Hospital, September 30.

He spoke on Tropical Sprue.

BRITISH MATERNAL AND INFANT MORTALITY

WALTER ELLIOT, British Minister of Health, has announced the lowest maternal mortality rate in England and Wales in history. A rate of 3.1 per 1,000 births places Great Britain among the nations with the lowest national records; and the infant mortality rate of 58 per 1,000 births compares with the lowest on record for Great Britain of 57 in the year 1935.

Commenting on a slight increase in the deaths from tuberculosis, Mr. Elliot said: "We cannot afford to lose every year nearly 30,000 persons from tuberculosis and nearly 70,000 from cancer, nor can we view with complacency the loss of nearly 2,000 mothers and more than 35,000 children under the age of one.

PERSONALS

Central States

DR. BERT ANDERSON, of Victoria, Kans., has been appointed a member of the Kansas State Board of Health, for a term of 3 years.

MORLEY B. BECKETT, M.D.,[†] of Allegan, Mich., who recently resigned as County Health Officer, will continue as Director of the Allegan and Van Buren County units.

[†] Member A.P.H.A.

DR. WALLACE E. CHILDS, of Madison, Ind., was appointed, July 1, Director of District Health Unit No. 1, consisting of Gibson, Pike, Posey, and Warrick Counties.

JAMES A. DOLCE, M.D.,† of Charlotte, Mich., has been appointed Assistant Director and County Health Officer of Allegan County.

OTTO K. ENGELKE, M.D., has assumed his duties as Health Commissioner of Adams County, Ohio, where he will reorganize the county health department.

D. CLARE GATES, DR.P.H.,† formerly Field Secretary of the Michigan Joint Committee on Health Education, Ann Arbor, Mich., has been appointed Director of Health Education, North Dakota State Department of Health, Bismarck, N. D., effective August 15.

JOSEPH H. KINNAMAN, M.D.,† of Baltimore, Md., has been appointed Assistant Health Commissioner of Peoria, Ill., with supervision of school health activities, effective August 15.

L. F. HALL, M.D., formerly Health Commissioner of Cuyahoga County, Ohio, has been appointed Commissioner of Health of the City-County Health Department of Helena, Mont., effective September 1.

WALTER H. HARTUNG, M.D., Ohio State Health Director, announces that the State Health Department is starting a drive against venereal diseases, the program to be financed by state-federal funds. The plan contemplates expanding venereal disease clinics in the larger cities by increasing the number of physicians, technicians, and clerks.

BENJAMIN LIEBERMAN, M.D.,† has resigned as Director of School Hygiene in the Milwaukee, Wis., Health Department, to become Director of Health Service at the Milwaukee State Teachers' College.

ROBERT A. LIGHTBURN of Crestline,

Ohio, has been appointed to the position of health education secretary and general assistant on the staff of the Onondaga, N. Y., Health Association. Mr. Lightburn was formerly connected with the Ohio Public Health Association.

CLIFTON C. E. MERRITT, M.D.,† of Iron Mountain, Mich., has resigned as Health Officer of Dickinson County, to succeed RAGNAR T. WESTMAN, M.D.,† as Director of the Bay County Department of Health, Bay City, Mich.

DR. ROSCOE T. NICHOLS, of Hiawatha, Kans., has been appointed a member of the Kansas State Board of Health, for a term of 3 years.

RUSSELL E. PLEUNE, M.D.,† of Lansing, Mich., formerly in charge of the Bureau of Venereal Disease Control for the Michigan State Department of Public Health, has been named Director of the Dickinson County health unit, effective September 1. He succeeds CLIFTON E. MERRITT, M.D.†

DR. ALBERT W. RATCLIFFE has been appointed Assistant to DR. CLYDE G. CULBERTSON, Chief of the Bureau of Bacteriology and Pathology of the Indiana State Department of Health.

LEWIS C. ROBBINS, M.D., C.P.H.,† of Indianapolis, Ind., has been appointed Acting Chief of the Bureau of Local Health Administration of the Indiana State Department of Health, during the absence of JOHN W. FERREE, M.D.,† Chief of the Bureau, who begins a year's graduate work at Johns Hopkins University September 1.

OSCAR D. SCHWARTZ, M.D.,† of Detroit, Mich., has been appointed Assistant Director of the Social Hygiene Division of the Detroit Department of Health.

* Fellow A.P.H.A.

† Member A.P.H.A.

H. J. SHAUGHNESSY, Ph.D.,† formerly chief of the Laboratory Service of the Illinois State Department of Health, who during the last year has been a member of the Department of Bacteriology and Public Health at the University of Colorado School of Medicine at Denver, has resigned to resume his former work in Illinois.

V. K. VOLK, M.D.,* of Saginaw, Mich., was recently appointed to fill the newly created position of Medical Superintendent of Saginaw County Hospitals; he is also Health Officer of the County.

ROY B. WEATHERED, M.D.,† of Kansas City, Mo., will succeed LAWRENCE F. STEFFEN, M.D., of El Dorado, Kans., as Health Officer of Butler County.

RAGNAR T. WESTMAN, M.D.,† of Bay City, Mich., has resigned as Director of the Health Department of Bay County.

Eastern States

HENRY D. CHADWICK, M.D.,* Commissioner of Public Health in the Commonwealth of Massachusetts since 1933, has resigned, effective September 1, to accept the position of Medical Director and Assistant Superintendent of the Middlesex County Sanatorium in Massachusetts.

CHARLES F. CHURCH, M.D.,† who for 3 years has been Director of Research of the Rockefeller Nutrition Fund at the Children's Hospital, Philadelphia, Pa., and associate in the Department of Pediatrics, University of Pennsylvania, will resume his work at the School of Public Health, University of Michigan, Ann Arbor, after visiting state departments of health during the summer in New York, Tennessee, Kentucky, and Michigan.

VICTOR G. HEISER, M.D.,* who until recently was an Associate Director of the International Health Division of the Rockefeller Foundation, has

been appointed Research Director of the Committee on Healthful Working Conditions of the National Association of Manufacturers, New York, N. Y. It has been announced that a survey of plant conditions will be started and that an information service will be provided for more than 75,000 factories, each of which employs from 25 to 2,000 workers. DONALD M. SHAFER, M.D., formerly of the Medical Department, Standard Oil Company of New Jersey, will be associated with Dr. Heiser.

ERNEST NEWMAN, M.D., C.P.H.,† who for 7 years has been employed as diagnostician in the Bureau of Preventable Diseases, New York City Department of Health, has been appointed Director of the Marathon County Health Unit at Wausau, Wis.

Southern States

DR. NOEL M. AKERS, of Macon, Ga., has been appointed Health Commissioner of Emanuel County.

THOMAS H. BLAKE, M.D.,† of Charleston, W. Va., Director of the Division of Maternal and Child Hygiene, has been named Director of County Health Work of the State Department of Health, succeeding ALBERT M. PRICE, M.D.†

EARL P. BOWERMAN, M.D.,† of Trenton, Tenn., has been named Health Officer of Gibson County.

DR. JOSEPH LINDSAY COOK, of Winston-Salem, Assistant County Health Officer and Medical Superintendent in charge of the Forsyth County Hospital, has resigned to take charge of a syphilis control program in Guilford County, N. C.

WARREN F. DRAPER, M.D.,* Washington, D. C., Assistant Surgeon General, U. S. Public Health Service, and recently Chief of the Division of Personnel and Accounts, has been ap-

* Fellow A.P.H.A.

† Member A.P.H.A.

pointed as the first incumbent of the newly created position of Executive Officer of the U. S. Public Health Service. Dr. Draper, who is a graduate of the Harvard Medical School, has been identified with the Service since 1910 and has had a wide variety of experience in many aspects of public health. For several years prior to 1934, Dr. Draper served as State Health Officer of Virginia.

J. W. ERWIN, M.D.,† of Savannah, Tenn., Health Officer of Hardin County, has been appointed Health Officer of Giles County, Tenn., to succeed DR. WILFRED N. SISK, of Pulaski, who is taking a course in venereal diseases at Johns Hopkins University School of Medicine, Baltimore, Md.

DR. THOMAS K. FAIREY, of Johnston, S. C., has been appointed Health Officer of Union County.

DR. BENJAMIN F. HAND, JR., formerly of Waynesboro, Miss., has been appointed itinerant Health Officer for the Mississippi State Board of Health, to aid county health officers in the examination of preschool children.

DR. ISAAC F. HUDSON is the new Health Officer of Stamford, Tex., succeeding the late DR. NATHAN H. BICKLEY.

LAWRENCE KOLB, M.D., formerly Chief of the U. S. Public Health Service Hospital at Lexington, Ky., has been appointed Assistant Surgeon General in charge of the Division of Mental Hygiene of the Service, succeeding WALTER L. TREADWAY, M.D.

DR. JAMES L. MIMS, of Chester, S. C., has been appointed Health Officer for Jasper County, succeeding DR. JOHN B. WALLACE, of Fountain Inn, who resigned to return to private practice.

THOMAS W. NALE, M.D.,† of Charleston, W. Va., Assistant Director of the Division of Maternal and Child Hygiene of the State Department of Health, has been named Director, to succeed THOMAS H. BLAKE, M.D.†

ALBERT M. PRICE, M.D.,† of Charleston, W. Va., formerly Director of County Health Work in the State Department of Health, has been appointed collaborating epidemiologist and Director of the Division of Communicable Diseases.

DR. DON PRICE, Secretary of the Henderson County Medical Society, has been named Health Officer of Athens, Tex., to succeed DR. JOHN K. WEBSTER.

DR. W. T. RAINEY, formerly of Brownsville, Tenn., has been appointed Health Officer of Lake County, succeeding DR. JAMES P. MOON, of Tiptonville, who is to become a member of the unit in Dyer County.

GUY V. RICE, M.D.,† of Chillicothe, Tex., has been appointed Health Commissioner of Wayne County.

DR. GASTON W. ROGERS, U. S. Army Medical Corps, retired, has been appointed Assistant District Health Officer on a full time basis in charge of Chatham, Person, and Orange Counties, with headquarters in Pittsboro, N. C.

DR. BENJAMIN A. STAFFORD, JR., formerly of Temple, Tex., has been appointed Health Officer of the Sharkey-Issaquena County Unit, succeeding DR. ROBERT H. DEJARNETTE, who was transferred to Alcorn County. Sharkey and Issaquena Counties made joint appropriations for a combined full time health unit with centers in each county.

SENIOR SURGEON PAUL M. STEWART, Washington, D. C., for the past 3 years Medical Director of the U. S. Employees' Compensation Commission, has been appointed Assistant Surgeon General in charge of the Division of Personnel and Accounts, to succeed WARREN F. DRAPER, M.D.*

* Fellow A.P.H.A.

† Member A.P.H.A.

DR. RICHARD M. STREET, M.D.,† of Laurens, S. C., recently resigned as Health Officer of Abbeville and Laurens Counties.

DR. ROBERT W. TAYLOR, of Lufkin, Tex., has been appointed Health Officer of Lufkin, succeeding Dr. DENMAN C. HUCHERSON, resigned.

WALTER L. TREADWAY, M.D., recently Assistant Surgeon General in charge of the Division of Mental Hygiene in the U. S. Public Health Service, Washington, D. C., has been transferred as Medical Officer in charge of the U.S.P.H.S. Hospital in Lexington, Ky., to succeed LAWRENCE KOLB, M.D.

Western States

DR. ADOLPH FRANK BREWER, of Redwood City, Calif., has been appointed Health Officer of Solano County. New full time health units were organized for Solano and Sonoma Counties, effective July 1.

His Majesty, the King of Italy and Emperor of Ethiopia has conferred the Cross of Cavaliere of His Order of the Crown of Italy upon J. C. GEIGER, M.D.,* Director of Public Health of the City and County of San Francisco, Calif., "for services of distinction in the field of public health."

BENJAMIN L. GRIMES,† of Juneau, Alaska, has resigned as Territorial Sanitary Engineer of Alaska, to accept a position with the Oregon State Board of Health, Portland, under CARL E. GREEN,† State Sanitary Engineer.

DR. FRANCIS J. PETER has been appointed Health Officer of Turlock, Calif., succeeding Dr. CHARLES E. PEARSON.

DR. PAUL W. SCHRIER has been appointed Health Officer of Atwater, Calif., succeeding Dr. CLARENCE C. FITZGIBBON, of Merced. Dr. Fitz-

gibbon is Health Officer of Merced County.

DR. FRANK E. SOHLER, JR., has been appointed Health Officer of Cloverdale, Calif., succeeding Dr. DONOVAN C. OAKLEAF.

DR. BURTON L. ZINNAMON,† of San Francisco, Calif., has been appointed Health Officer of Sonoma County, effective July 1. The unit was recently placed on a full time basis.

Puerto Rico

EDUARDO GARRIDO-MORALES, M.D., Dr.P.H.,* Commissioner of Health of San Juan, Puerto Rico, had the honorary degree of Doctor of Science conferred upon him by Louisiana State University on July 28. Dr. Garrido-Morales is a graduate of the University of Virginia School of Medicine and a Doctor of Public Health degree from Johns Hopkins University.

Foreign

SILVESTRE LÓPEZ PORTILLO, M.D., M.P.H.,† after obtaining his C.P.H. degree in Boston, Mass., was recently appointed State Health Officer of San Luis Potosí, S. L. P., Mexico. He succeeds FELIPE MALO JUVERA, M.D.,† who is now going to study at the School of Public Health, Johns Hopkins University, Baltimore, Md.

SIR ARTHUR NEWSHOLME,* late Principal Medical Officer of the Local Government Board, was presented with the Jenner Medal of the Royal Society of Medicine, London, at a recent general meeting of the Fellows of the Society. The medal is awarded "for distinguished work in epidemiological research or for pre-eminence in the prevention and control of epidemic disease."

* Fellow A.P.H.A.

† Member A.P.H.A.

K. S. VISWANATHAN, M.D., M.P.H.,† has sailed for India after a year spent at the Harvard School of Public Health where he received the Master's degree. He is the Assistant Professor of Hygiene at the Madras Medical College in India.

DEATH

I. MALINDE HAVEY, R.N.,* National Director of Public Health Nursing and Home Hygiene for the American Red Cross, Washington, D. C., died September 7, at the Baker Memorial Hospital, Boston, aged 51. She was buried with national honors in Arlington Cemetery, Washington. Miss Havey was in charge of disaster work during the 1927 Mississippi

flood, and the Mississippi and Ohio River floods of 1937. As a nurse during the World War she was twice decorated by the British and French Governments for bravery under fire. Appointed Director of the Public Health Nursing Service more than 12 years ago, she directed Red Cross nursing activities for a time in the New England flood of 1936. Miss Havey, who was born in Stoughton, Wis., and trained in nursing at the Chicago Hospital, made her home in Washington. She became a member of the Association in 1922, and had been a Fellow since 1932.

Opportunities and Responsibilities of the Health Officer in Connection with the Federal Housing Acts*

C.-E. A. WINSLOW, DR.P.H., F.A.P.H.A.

Professor of Public Health, Yale School of Medicine, New Haven, Conn.; Chairman, Committee on the Hygiene of Housing of the American Public Health Association

THE American Public Health Association began its career with a clear recognition of the importance of housing as a public health problem. The very first volume of *Reports and Papers* of the Association for 1873 contains a report by Carl Pfeiffer, F.A.I.A. on "Sanitary Relations to Health Principles of Architecture." The second volume of *Reports and Papers* for 1874-1875 blossomed out with no less than 5 papers on housing problems, 2 by Dr. Ezra M. Hunt of New Jersey and one each by Dr. E. H. James of New York, Dr. Henry W. Dean of Rochester, and F. H. Hambleton, C.E., of Baltimore. Dr. Dean put his finger on the crux of the problem when he said: "I have not at present any special interest in the construction of dwellings for the affluent. Given the

sanitary principles in the substructure, the superstructure in its general appointments is commonly well provided for sunlight, and in the form and capacity of its living rooms. In the tenements and houses provided for the middle and laboring classes, the classes constituting three-fourths or more of our population, and the source of a still larger proportion of native born children, the State should see to it that such homes are made healthy, and preserved in such conditions as to conduce to the maintenance of health."

The third volume of *Reports and Papers* for 1875-1876 again contains 4 papers on housing problems, by Dr. Hunt, once more, and by such distinguished leaders of the Association as Dr. Stephen Smith, Col. George E. Waring, Jr., and Prof. E. N. Horsford. Dr. Smith showed that the proportion of the total mortality of New York City contributed by its tenement population was decreasing. He attributed this to

* Presented on behalf of the Committee on the Hygiene of Housing before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

sanitary inspection of tenements and urged the extension of such service to other dwellings; and Professor Horsford calls for "a new profession, akin to that of engineering, or to that of engineering and medicine united." The expert he visualizes should be "the 'house physician,' 'the sanitarian'—the efficient and consulted brother of the 'family physician.'"

The specters of carbonic acid, crowd poison, sewer gas and ground air stalk across these yellowed pages; yet in many of the papers, notably those of Dr. Ezra Hunt, there is much that remains sound and significant after sixty-five years.

Later on, the early interest of our Association in physiological and hygienic problems, in broad environmental and social influences, faded in the brilliant light of the germ theory of disease. For half a century the struggle between microbe and host dominated the scene and only during the last few years have the potent factors of diathesis on the one hand and of social environment on the other come back into the picture.

Today, we again recognize that while it is difficult or impossible to obtain a quantitative evaluation of the exact relation between housing conditions and mortality rates there are numerous aspects of housing which, indubitably and in important degree, do influence human health in its physical, emotional and social aspects.¹ We may perhaps say, with Stephen Smith in 1876, "The great want of American communities today is sanitary architecture in our dwellings and sanitary supervision in their management."

As a result of developments during the past 5 years, this "great want" is at last in the way of being met; and it is these developments which make the problem of such urgent moment to the health officer.

The United States has been singularly

backward, as compared with the nations of Western Europe, in its solution of this problem. It has been estimated that nearly 6 million new dwellings would have been needed in 1937 to meet the quantitative housing shortage and to replace qualitatively the most unsuitable slum areas, and that provision for increasing population and replacement of obsolescent dwellings will call for over 10 million more dwellings by 1950. To catch up with minimum needs by that date will, therefore, call for more than a million new dwelling units a year.

In the years between 1932 and 1937, the federal government for the first time attacked the situation, chiefly—so far as actual construction was concerned—through the Housing Division of the Public Works Administration and the Resettlement Administration. The PWA, which was the agency dealing with urban housing, built 51 projects in 35 cities of 20 states, 2 territories, and the District of Columbia.

The government housing program was put on a permanent basis by the passage of the Wagner-Steagall Act of 1937. This act created the United States Housing Authority as a "body corporate of perpetual duration," "to provide financial assistance to the states and political subdivisions thereof for the elimination of unsafe and insanitary housing conditions, for the eradication of slums, for the provision of decent, safe and sanitary dwellings for families of low income, and for the reduction of unemployment and the stimulation of business activity." To carry out this program, Congress has authorized the Authority to lend 800 million dollars during its first 3 years. The Act requires the elimination by demolition, condemnation and effective closing, or the compulsory repair or improvement of an unsafe or insanitary dwelling unit in the locality for every new dwelling unit in a housing project. The elimina-

tion of slum dwellings may be deferred, in the discretion of the Administrator, where an acute housing shortage exists. All slum clearance and low-rent housing programs must be initiated by the localities themselves (not by the federal government as in the earlier PWA projects); and local initiative is taken by a duly constituted "public housing agency." This agency may be a municipality, county, or state (duly authorized under proper enabling state legislation), but will normally be a local housing authority which is a public corporation, without taxing power, created or authorized by state law for the purpose. Thirty-three states have now passed enabling acts creating "public housing agencies."

In addition to the provisions of the Wagner-Steagall Act and quite independent of it, is the program provided for in the National Housing Act of 1938 to stimulate private building operations for families on a higher economic level. Under this act the federal government will act as a mortgage guarantor for projects which conform to certain specified conditions, including minimum health standards. This program will be administered by the Federal Housing Administration which is a government agency entirely distinct from the United States Housing Authority.

It is the U. S. Housing Authority under the directorship of Nathan Straus which will be concerned with low-cost housing; and it is the program of this agency which is of most vital concern to the health officer.

In many European countries, the guidance of the national housing program lies in the hands of public health authorities. In England, for example, the comprehensive plans, finally crystallized in the Housing Acts of 1935 and 1936, are administered entirely by the Ministry of Health. The last report of the Ministry outlines the 3 objectives

of that Act as follows: (1) the clearance or other appropriate treatment, within a prescribed period, of unfit houses and the effective housing of those displaced; (2) the abatement of excessive overcrowding and the rehousing of the overcrowded families; (3) the assurance of an adequate regular production of good and cheap houses to meet ordinary working-class demands outside the slum and overcrowding sphere. The first of these objectives has been essentially attained and the second is now in process of realization, following a comprehensive survey of overcrowding completed 2 years ago. The Minister of Health reports that between 1918 and March, 1936, 1,259,387 houses have been completed under the successive Housing Acts with government contributions of 164,489,622 pounds.

In the development of the early stages of our American housing program—although no such primary health department responsibility has yet been recognized—both voluntary and official health agencies have played a substantial part. In Cincinnati, Cleveland, Philadelphia, Pittsburgh, and Washington, individuals or groups of public health workers have been active in promoting a study of housing needs and in stimulating remedial measures.

In Chicago, as in other cities, the Board of Health has control over heating, lighting, ventilation, plumbing, and drainage within buildings, and controls dwelling conditions from the time that plans for new and remodeled structures are submitted for approval, through the period of construction and during occupancy. Furthermore, in the report of Dr. Bundesen's Bureau of Sanitary Engineering—as far back as 1923–1925—we find constructive discussion of the general housing shortage and its cure as well as analysis of specific structural defects. In 1934 Dr. Bundesen was made Chairman of the Mayor's

Committee on Sub-Standard Housing, on which the Fire Department, and the Departments of Buildings, Loans and Public Works, as well as Public Health, were represented. During the next year and a half this committee brought about the demolition of several thousand sub-standard dwellings which were deemed a menace to public health and safety.

In Hartford, in 1934, the Mayor's Housing Commission was set up at the request of the Health Department. In Birmingham, the County health officer in the same year instigated an Advisory Council which made numerous surveys and was directly responsible for the creation of a local housing authority and the construction of a negro project.

In Memphis, the Health Department has been an outstanding leader in this field. Dr. L. M. Graves and A. H. Fletcher have presented 2 valuable papers before the Health Officers Section of the A.P.H.A.² reviewing the progress which has been made. These health administrators believe that "good housing is an essential foundation on which to build a well rounded health program." They add that, "in the larger cities where so much needs to be done, the health department may not actually be concerned with the administration of a housing program, although it will certainly be called on to investigate complaints in regard to poor housing conditions and will be in a position to make its influence felt in trying to work out a solution. In many cities the health department may be the logical agency to take the prime interest in, and to define to a large extent the housing problem and undertake its solution." Dr. Graves and Mr. Fletcher compiled a comprehensive housing study in 1934 and a second more intensive survey of slum areas in 1937; and, as a result, are in position to replace haphazard response to complaints in regard to insanitary condi-

tions by a constructive and basic health program.

In 1937, an intensive survey was made of all tenement buildings and dwelling houses in one ward of the city of Newark, by the Health Department of that city under the direction of Dr. C. V. Craster; this survey is thought to have aided materially in securing for the city an earmarking of 12½ million dollars for low-cost housing.

These instances of leadership by American health officers in the housing field by no means exhaust the record. They simply illustrate the fact that the day is past when housing was merely a problem for private speculative enterprise and when the health officer could limit his work to the negative task of eliminating the more obvious insanitary conditions, with little thought for the positive challenge of planning a program of adequate housing for the future.

During the past 5 years, when the initiative for new housing projects has come from Washington, the opportunity for active participation by the health officer could easily be ignored. Now, however, the whole picture has changed. Housing under the Wagner-Steagall Act is a local municipal enterprise. Destruction of slums and creation of good new housing are linked in a new type of municipal housekeeping enterprise, fundamentally dominated by health needs in their broad connotation.

This concept of civic housekeeping, and the housing movement which is a basic part of it, spring from a new philosophy which is emerging with respect to our cities of today and to the possibilities of urban living in the future. Workers in health and social reform are not alone in recognizing that slums and blighted areas present a menace to the stability of our whole urban structure.

The unplanned growth of cities; the flight of many people from deteriorating

urban areas to suburban regions where they seek to reestablish a decent environment: the resulting decline in central population densities, land values and tax revenues, and the diminishing usefulness of schools, parks, utilities and other public investments in such areas of shrinking population—these have aroused the serious concern of thoughtful mayors, assessing officials, city planners, and civic leaders of all sorts. There is an increasingly general acceptance of the proposition that great sections of our cities must, physically and literally, be rebuilt in order that those cities may enjoy a stable economy and a durable type of growth.

Progressive thinkers in city planning are turning away from their earlier preoccupation with the design of monumental civic centers, arterial streets and landscaped parkways, and from zoning practices suited to a boom psychology. From these superficial trappings of city growth they are turning to the central problem of human living, to the task of furnishing well planned and well located communities of dwellings. Thus only, can we provide a material matrix for a type of urban life which shall approximate the ideals of physical, mental, and social health. Thus only, can planning be developed on a basis which visualizes a relatively stable use of urban land and a reasonably permanent allocation of schools, parks, and other public services. City planners, in other words, are coming to recognize good housing as the only solid basis for urban development.

Under the guidance provided by this viewpoint, and with the immediate stimulus afforded by the new public housing legislation, great sections of our cities are going to be rebuilt, and within our own generation. In cities such as Cleveland, where over 9 million dollars has been spent and nearly 9 million more is earmarked, an impressive start has already been made. New

York City has built about 25 million dollars worth of U. S. projects and has 53 million dollars earmarked.

Although the immediate incentives of this new city planning and housing activity are many, the concept of health is central to all of its objectives. Those administrators and technicians who have responsible places in the housing program are increasingly anxious that the public health viewpoint shall be actively represented in the execution of that program. From intimate knowledge of the reception which has been accorded by housing groups to the first work of our Association's Committee on the Hygiene of Housing, I can say to you without qualification that the people who count in the housing field are waiting eagerly for the contribution which the public health profession can make. The cordial reception extended to our committee, on a national scale, by the National Association of Housing Officials, the American Federation of Housing Authorities, the American Institute of Architects, will be duplicated by local housing and planning officials as rapidly as local health officers and their departments demonstrate that they are ready and able to cooperate.

Just what is it that the health officer can contribute?

There are 5 stages of the housing program at which the influence of the health officer—with his basic knowledge both of local physical conditions and of local racial and social needs—should be of prime importance.

First of all, there is the problem of the housing which now exists, and the opportunity of improving and stabilizing it by the vigorous exercise of powers clearly vested in the health department. For it will be idle to build new housing if existing dwellings which can be improved are not improved, and if areas which could be saved from blight are allowed to deteriorate faster

than new housing can be built. On this level, housing enforcement programs such as those of the Chicago and Memphis departments warrant the closest study.

Activities of this sort are suggested in the *Appraisal Form** of the Association, which now includes the following questions with respect to health department activities:

a. Are data maintained by any city department concerning the total supply of dwelling accommodations including new construction, demolition, and vacancy?

Does any city department maintain a file of "sub-standard" (structurally unsafe) dwellings?

b. Are all plans for new dwellings or alterations on existing dwellings examined, and is approval mandatory, by the health department or some other city department, before building operations are commenced, in order to insure adequate space, light, ventilation, and sanitary equipment?

If approval of plans is by a department other than the health department, was the health department concerned in the establishment of standards for space, light, ventilation, sanitary equipment?

c. Does the health department have legal powers to demolish or control the occupancy of such "sub-standard" dwellings?

d. Does the department have power to inspect existing dwellings with regard to space, light, ventilation, and sanitary equipment?

Closely related to such improvement of existing sub-standard but improvable dwellings is the second problem—that of the slum elimination which must parallel or follow the development of any new housing project under federal grants. It is conceivable that such sanitary enforcement programs as have been outlined under my first category above would result in the elimination, by improvement, of sub-standard dwellings equal in number to those constructed by the local authority, and that credit for these eliminations could be granted. But it is the intent of the

Act, and it will generally be the fact, that the worst slums must be cleared by demolition. And the U. S. Housing Authority has ruled that this must be done not later than 2 years after a local housing shortage has been relieved by new construction.

Where the local authority elects to build new projects on slum sites, and where clearance of these sites provides the necessary slum elimination, the authority's powers of eminent domain will generally enable it to proceed without legal assistance from other city departments. But where the authority builds on vacant land, and must then select equivalent slum areas for later demolition, it will often be found that its rights of eminent domain do not apply, and the authority must depend on other city departments—health, building, police—for justification of the clearance. Even in the former case there should be agreement between the health department and the authority that the slums to be cleared are, in fact, those most suitable for clearance.

Who better than the health officer has the knowledge and the equipment to determine which are the "unsafe and insanitary" dwelling units to be eliminated? His inspectorate is the one existing agency which has or should have, the information necessary for determining the facts. It is the health officer who already possesses broad powers under the general laws governing control of nuisances, to be enforced by fines, by summary abatement, or by condemnation. In most urban communities, these powers are supplemented by specific statutory regulations governing building construction and occupancy. Finally, in certain jurisdictions it has been provided that a tenement may not be occupied until it has received a certificate from the board of health, bringing in the very convenient principle of licensing power. The knowledge now at the command of a

* *Appraisal Form for Local Health Work* (1st ed.), 1938, p. 156.

well organized health department should furnish the basis for housing demolition surveys and greatly simplify their execution.

A concern with the improvement of existing housing and with the condemnation and demolition of areas which are beyond improvement is obviously only the beginning of that interest which the health officer should display in this fundamental field of public health. It is of equal importance that he should play his part in the planning of the new public housing projects which are to replace the slums. It is to him that we should look for counsel in regard to those factors in the design of new dwelling units which influence health and which are determined by basic physiological and psychological needs, by the necessity for protection against contagion and accident. He and his staff know more about the racial groups of the city, their living habits, their psychological reactions, than any other municipal officers. Their counsel should be invaluable in locating new projects and in planning their design and arrangement. The availability of local clinics and other health facilities may often be a factor of fundamental importance. Some of the projects already constructed (as in New York City) include space for health department activities in their buildings; and this is a tendency which could be followed with advantage in the future.

Nor does the health officer's responsibility for these new housing projects cease when construction is completed. There are now about 50 such projects already in operation in our municipalities. They are, in general, adequately planned; but realization of the objectives of healthful housing depends on wise selection of tenants and on continuing supervision of occupancy. Under the new decentralized federal housing program, tenants must be chosen within specified income levels; but even

with such limitations there is real danger that the recommendations of local politicians may carry undue weight. In such contingencies, the presence of the health officer on the authority or on a board of review for tenant selection and regulation of occupancy should prove of inestimable value. We must remember that the health officer alone has the machinery to enforce regulations in regard to occupancy and sanitary maintenance on a continuing city-wide basis.

Finally, we should not permit our vision to be limited by the immediate problems of slum clearance and the provision of low-rent housing under the U. S. Housing Administration. These are parts of a more comprehensive plan for the best attainable housing facilities serving the entire community. An important factor in this problem is the Federal Housing Administration which as a mortgage guarantor is in position to stimulate the construction of the right type of housing on a commercial basis for persons in a middle income range. The health officer, if properly qualified, might play an important rôle in integrating public and private housing enterprises, and in coordinating the activities of architects, builders, and financiers with the real health needs of the people to be served. His professional training and his position of impartial objectiveness might be made a strong factor in holding both public and private housing to their underlying objectives, and encouraging private enterprise to play its part in the total program.

All this is a tremendous challenge to us as public health workers. The first step for the health officer who is ready to meet that challenge is, obviously, to become fully familiar with the state and local legislation in this field and with the administrative machinery which has been set up to make it operative. A second step should be to analyze the

data now in health department files and to determine what further surveys are necessary to make the actual local housing situation clear. WPA forces are being permitted to furnish assistance in this field which should prove invaluable; and recent reports prepared under the direction of R. H. Britten as a part of the National Health Survey of the U. S. Public Health Service will give the local health officers of cities included in that survey first-hand data as to housing conditions which will be of the most fundamental importance.

In developing such affiliations, the health officer will find a knowledge of the wider national movement of substantial advantage. This can be furthered materially by contact with the National Association of Housing Officials.* The publications of this association, particularly its pamphlets on *Demolition of Substandard Housing*, and *Planning for Low-Rent Housing*, will be found of interest to every health officer. The U. S. Public Health Service is in position to aid you in your tasks through the appointment of Dr. J. M. DallaValle as its officer specifically assigned to study the housing problem.

In particular, however, I am here today to offer you the assistance of your own A.P.H.A. Committee on the Hygiene of Housing. One of the chief purposes in establishing this committee was to aid the health officer in meeting this new demand upon his time and energy. We have prepared—primarily for your use—a report on the *Basic Principles of Healthful Housing*.³ This report has already been distributed by the National Association of Housing Officials, at the suggestion of Housing Administrator Straus, to local authorities as a guide in the planning of their projects. Together with a companion report of N.A.H.O., it has been tenta-

tively approved by the two chief housing agencies of the federal government for official publication. This committee of the A.P.H.A. has therefore already made some contribution to the cause on your collective behalf. We trust that it may help you individually to orient your services to the cause in your respective areas; and, within limits of time and money, the membership and staff of the committee are at your disposal for contact with existing literature in this field and for counsel as to particular local problems. We believe that full and active participation in the local housing program will enable you as health officers to render a contribution toward the promotion of public health which is logically yours and which will open up one of the most vital and most promising areas of public health service for the coming years.

In its medical aspects the public health program began as a repressive police activity concerned almost wholly with isolation and quarantine. Today it has taken on a positive constructive aspect, and in its clinics, its nursing, and its educational work it is primarily concerned with direct service to the individual citizen. In the field of sanitation (except for the provision of public water supplies and sewerage systems) the emphasis is still largely on police control. The housing program offers to the sanitarian a unique opportunity to pass over into the service field and to gain the support which comes from appreciation of contributions rendered directly to the people whom he serves.

Administrative Control of Food Handlers and Places Dispensing Food and Drinks

KATHERINE MARDEN, F.A.P.H.A., JOSEPH M. CURRY,
D.V.S., LOUIS J. HOROWITZ, AND BENJAMIN G.
HORNING, M.D., F.A.P.H.A.

*Director, Bureau of Laboratories; Director, Bureau of Food and
Sanitation; Chief Food and Milk Inspector; and Health
Officer, Board of Health, Hartford, Conn.*

THE administrative control of food handlers and places dispensing food and drinks is one of the most difficult problems in the field of public health. The subject has been receiving much attention from public health officials during the past few years, and considerable data concerning the problem have appeared in the literature. The purpose of this article is to review the subject briefly and to describe recent activities of the Hartford Board of Health in this field.

Food handlers play a rôle of some importance in maintaining the health of the community. This group includes housewives and servants in private homes, as well as food handlers in public and semi-public places. The housewife may not be the cause of an extensive outbreak of disease, but she may cause illness among her own family and guests by failure to observe proper precautions in storing, preparing, and serving food. It is the responsibility of health officials to instruct food handlers concerning the danger of food-borne diseases and their prevention. It is also important that consumers know what is expected of food handlers in the way of personal hygiene and other preventive measures.

The germs of many communicable diseases may be present in the human nose, mouth, throat, genitourinary and gastrointestinal tracts, and leave the body with excretions from these parts. In this way diseases may be spread by case or carrier, either directly or indirectly. If the illness is spread by one with symptoms, it is usually easy to find the source of infection. If spread by carrier, it is more difficult. It is well known that the following diseases, as well as others, may be spread by contaminated food:

Amebiasis	Poliomyelitis
Diphtheria	Scarlet fever
Dysentery, bacillary	Streptococcus sore throat
Food poisoning	Tuberculosis
Paratyphoid fever	Typhoid fever

These and many other diseases, including those listed below, may also be spread indirectly by contamination of dishes and other utensils, or directly from food handlers to customers:

Chickenpox	Pneumonia, broncho
Conjunctivitis, infectious	Pneumonia, lobar
Encephalitis, epidemic	Smallpox
Influenza	Syphilis (rarely)
Measles	Common cold
Meningococcus meningitis	Vincent's angina
Mumps	Whooping cough

Personal cleanliness is one of the

fundamental principles of food handling. Proper washing of the hands after using the toilet, after contamination from coughing or sneezing, and before beginning to prepare or serve food is of the utmost importance. The hands may become contaminated with discharges from the nose, mouth, throat, genitourinary and gastrointestinal tracts, and may be a menace to the public. If the hands are to be washed thoroughly, hot running water, soap, nail brush, and ample time are necessary. They should be dried on individual towels. The finger nails should be neatly trimmed and free from dirt at all times.

It has been shown that the routine examination of food handlers by supervisory authorities has had but little effect upon the incidence of disease. Compulsory laws, involving a large expenditure of money and frequently giving a false sense of security, would not seem to be justified. A number of cities which formerly issued health certificates to food handlers have discontinued doing so. From the standpoint of public health administration, experience indicates that the spread of such diseases as typhoid fever, syphilis, and tuberculosis can be controlled more satisfactorily and economically by investigating all cases and contacts in the community and bringing the sources of infection under control, than by routine examination of food handlers. However, a periodic health examination by a physician is highly desirable for the individual, and the Hartford Board of Health advises that it be done on a voluntary basis.

Many foods at room temperature serve as excellent media for the growth of certain disease producing germs. Great care must be taken in the preparation, storage, and dispensing of such foods. Before serving they should be heated to such a degree as will kill pathogenic bacteria. Food that is not intended for immediate consumption

should be placed under refrigeration. Many cases of illness result each year from the improper preparation and storage of cream filled pastry, meats, and other foods.

All foods should be given individual service. Serving forks, tongs, spoons, and other implements should be used to handle such foods as cake, candy, bread, and lump sugar. Persons preparing salads, sandwiches, and foods to be eaten unheated, should take the maximum precautions to prevent touching the ingredients with their hands.

Glasses, dishes, silverware, and other utensils in which food is prepared, stored, or served should be cleansed, disinfected and properly protected from contamination until used again. This protects the next person from germs which may have been left by the food handler, or by the customer who previously used the utensil.

LABORATORY STUDIES AND LEGISLATION

A laboratory study of drinking glasses from places dispensing food and drinks in Hartford was begun in the autumn of 1934 and continued through the summer of 1935.¹ The purpose of the project was to determine the efficiency of disinfection of glasses, dishes, and other eating utensils. One glass was examined from each of 200 drug stores, 232 taverns, and 198 restaurants—or a total of 630. The tavern glasses were examined during the winter and spring, and those from the restaurants and soda fountains during the autumn of 1934 and summer of 1935.

At the time the study was begun a review of the literature² revealed no accepted standard laboratory methods for such work, hence the results may not be comparable with similar studies elsewhere. It was necessary to develop a technic which would be relatively simple, and yet would give a representative bacteriological picture of conditions. At first only total plate counts were made

from supposedly clean glasses. As the study progressed, it was decided to determine the type of organism on the glass rim, and the bacteriological content of the entire glass.

The cultures were made in the establishments by a representative of the Board of Health. A definite amount of sterile water and a swab were provided for each glass. The water was placed in the glass and worked around in such a way as to wash down the bacteria, and then returned to the original bottle. The swab was rubbed around the rim of a second glass, approximately 1 inch from the top inside and outside, and returned to its tube. They were then brought to the laboratory and cultures were made within 1 hour. Agar plates were made from the glass washings and incubated for 36 hours. The swab was placed in a tube of sterile bouillon and allowed to incubate over night. It was found that this period of incubation was the most satisfactory for preventing over-growth by spore formers. In the morning the swab was removed from the tube, direct smears were made, and it was then discarded. The smears were stained by the Gram method. Blood agar and Endo plates were made from the broth tubes. After 24 hours' incubation these plates were examined macroscopically for hemolytic or coliform colonies.

A second bacteriological survey of glasses was begun in the autumn of 1935 and continued through the summer of 1936. In this study the rim of one glass from each of 690 estab-

lishments was cultured. By this time a routine laboratory technic had been developed. The laboratory technician taking the cultures was provided with 10 c.c. of sterile water in a test tube and a sterile dry swab wrapped in paper. Just before taking the culture, the swab was moistened in the water and rubbed on the rim of the glass, inside and out. The swab was returned to the tube of sterile water and brought to the laboratory. Before making the culture, the swab was shaken vigorously in the sterile water. This was continued until the cotton was nearly loosened from the swab. A measured portion of the water was used for a plate count, and a broth culture was made from the swab. A smear was made from the broth culture, stained by the Gram method, and examined for type of organism. Colonies on the agar plates were counted and the count was adjusted after figuring the dilution. A summary and comparison of the bacteriological findings of the two surveys will be found in Tables I, II, and III.

The results of the laboratory studies indicated that many places in Hartford were not adequately disinfecting eating utensils. A large percentage of glasses examined were found to be contaminated with bacteria commonly found in the human upper respiratory and gastrointestinal tracts. It was shown that rinse water of 130°F., as required by Board of Health regulation, would not properly disinfect eating utensils.

A careful survey of disinfecting agents and methods was made. It was con-

Staphylococci	169	26.8	148	21.4
Coliform	159	25.2	127	18.4

cluded that from the administrative point disinfection by hot water would be the simplest to supervise. The efficiency of certain chemical agents in disinfection was granted, but their supervision would not be practical in Hartford. Bacteriological studies were made to determine the minimum temperature and time needed for adequate disinfection. The new regulation was adopted on August 19, 1936, and became effective October 1, 1936.

Regulations Concerning the Cleansing of Glasses, Dishes, Silverware, and Other Utensils Used at Places Dispensing Food and Drink

a. All glasses, dishes, silverware, and other utensils used at places dispensing food or drink shall be washed after each service until clean to the sight and touch in warm water (110°-120° F.), containing soap or alkali cleanser.

b. After cleansing, all glasses, dishes, silverware, and other utensils, shall be placed in wire cages and subjected by immersion for at least 5 minutes to the bactericidal action of water heated to a minimum of 170° F.

c. Upon removal from the hot water, glasses, dishes, silverware, and other utensils shall be

stored in such a manner as not to become contaminated before being used.

d. Other equally effective methods of bactericidal action by heat, hot water, or steam will be approved.

e. When paper receptacles, ice cream cones, or other single service utensils are used for serving food or drink, they must be kept in a sanitary manner, protected from dust, flies, and other contamination.

A new regulation concerning the serving of food and drinks was also passed and an Inspection and Score Card System adopted.

Regulation Concerning the Serving of Food and Drink

a. Places manufacturing, preparing, and serving food and drink shall require all food handlers to wash their hands thoroughly with soap and water after using the toilet.

b. Places serving food and drink shall take the maximum precautions to prevent contamination of food and drink by hands of waiters and customers.

c. All food and drink shall be given individual service.

d. Places dispensing food and drink shall display the license and score card in such place as is plainly visible to the public, and is approved by the Board of Health.

TABLE IV
Bacteriological Examination of Glasses

Organism	1934-1935	1935-1936	1937-1938
	614	690	2,794
	Examinations	Examinations	Examinations
	Per cent	Per cent	Per cent
	Positive	Positive	Positive
Streptococci	15.3	14.3	0.3
Staphylococci	26.0	21.4	9.73
Coliform	25.3	18.4	4.76
No growth or spore formers	33.4	45.0	85.01

After sufficient time had been allowed for installation of equipment, and for instruction of proprietors and food handlers as to the necessity of adequate disinfection of utensils and observance of personal hygiene, a third survey was made. This included a plate count from the rim of glasses and a culture for the type of organism from all places dispensing food and drinks in the city. No attempt was made to classify streptococci or staphylococci as to hemolysis, and the Gram-negative bacilli were all classified as coliform organisms. The results are compared in Table IV with the studies made previous to the enforcement of the new regulations.

Total	100.00	100.00

DISINFECTING EQUIPMENT

Less than 10 per cent of places dispensing food and drinks in Hartford had equipment and plumbing which ful-

filled the requirements of the new regulations. Two difficulties presented themselves. Manufacturers did not make the type of equipment suitable for the smaller places, and the plumbing in many establishments, even with new equipment, was not capable of maintaining water at the desired temperature. Representatives of equipment companies, sanitary engineers, and plumbers conferred with representatives of the Board of Health. Apparatus was designed, and laboratory studies were made to determine whether it would disinfect eating utensils.

The Board of Health licenses 623 places to dispense food and drinks in Hartford. All have installed approved disinfecting equipment. The types of apparatus may be divided into 5 groups: (a) tanks with dish trays; (b) sinks with dish trays; (c) hot air disinfectors; (d) mechanical dish washers; (e) paper utensils. Most of the smaller places have installed the simple tank type. Many fountains have sinks with trays. The heat for the first two types is generated by gas, and the temperature regulated either by thermostat or thermometer. The hot air disinfecter was designed by a local company. Laboratory tests have shown that utensils are disinfected by this type of apparatus when exposed to 250°F. for 15 minutes. The larger establishments have mechanical dish washing. Table VI summarizes certain data concerning disinfecting equipment in use in Hartford.

TABLE VI
Data Pertaining to Disinfection

Type Equipment	Number Places	Disinfecting Space Average Cubic Inches		Heated by	
		Per Place	Per Customer	Gas *	Electricity
Tank with Trays	308	4,400	22.5	299	9

Totals and averages	623	4,771	18.9	530	56

* Includes 15 disinfectors heated with coal and 5 heated with oil.

INSPECTION AND EDUCATION

The Inspection and Score Card is a valuable aid to the Board of Health Educational Program. It was patterned from Figure 64 of *Recording of Local Health Work*, by Walker and Randolph.³ Their form was simplified and adapted to our local needs. It is required to be posted where it will be visible, and may be inspected by customers. A leather holder is provided by the Board of Health, and a duplicate Score Card is filed in the Board of Health office. The establishment is scored monthly. This does not mean that it is inspected only once each month as frequently it may be necessary to make several visits. Four points are allowed for each item. When practical, the place is scored by a different inspector each month.

The representative of the Board of Health makes the inspection in the presence of the manager and other employees. It is an educational visit. Each item is inspected carefully and criticisms and suggestions are made. If violations are found, a note is made on the back of the Score Card and a reasonable length of time is given for necessary corrections. The Score Card is proving a stimulus to establishments to improve the standard of their service. It gives the Board of Health an opportunity to educate food handlers in

the best methods of food handling and personal hygiene. The Score Card is also very helpful to the inspector. It provides him with a standard inspection procedure and a monthly record of each establishment for comparison.

DISCUSSION

It is impossible to estimate the amount of disease spread by food handlers and eating utensils. Lynch and Cumming⁴ made extensive studies of dish washing in several army stations. These investigators found that the influenza rate was much higher among men using dishes washed in the line, than among those who ate at the tables and whose dishes were washed in water of higher temperature. "In an epidemiological study of 66,076 troops it was shown that there was an influenza rate of 51.1 per 1,000 troops among those who had the advantage of collective washing of utensils, while among those who washed their own mess gear in warm water, the rate was 252 per 1,000."⁵ They concluded⁴ that if mess kit dish water is responsible for explosive outbreaks in the army, perhaps, common dish water in public eating places likewise is responsible for the spread of certain diseases.

Cumming⁶ sent questionnaires to public institutions in the United States. The 370 institutions replying formed

the basis for the report. These came from every state in the Union and from many different types of institutions. As a result he concluded that the major avenue of infection was through interchange of contaminated eating utensils. He found that the pneumonia mortality rate was higher in institutions than in the army or civil life, due perhaps to larger messing groups and lack of sanitary dish washing.

Cumming and Yongue⁷ stated that there were sound reasons for believing the sanitation of eating and drinking utensils is an important factor in disease control. They found that only 60 per cent of the contamination was removed by the washing process, but when the

hand or machine method was consistently carried out, there was 99 per cent reduction in bacteria.

In 1924 the city of Dayton, Ohio, began a study⁸ designed "to give greater protection to the eating out public." The investigators through a program of inspection, instruction, and laboratory examination have worked out a system of ratings which are published monthly in the bulletin of the Health Department.

That this method has been effective is shown by the fact that in 1925 only 28 per cent of the restaurants received the Class A or excellent rating, whereas 92.5 per cent received the Class A rating in 1933.

Laboratory studies (Tables I, II, and III) have shown that a high percentage of drinking glasses used in places dispensing food and drinks in Hartford were contaminated with bacteria from the upper respiratory and gastrointestinal tracts. The same condition was undoubtedly true of other eating utensils. A study made after the installation of disinfecting apparatus (Table IV) demonstrated a marked improvement in the bacteriological findings. The percentage of glasses adequately disinfected increased from 33.4 per cent and 45.9 per cent in the first two studies to 85 per cent in the last survey. This was too great a difference to be due to chance, and it seems fair to conclude that it was due to the program which included new legislation, the installation of disinfecting equipment, and mass education.

The Board of Health program to improve the sanitary condition of places dispensing food and drinks in Hartford has been received with enthusiasm by the public. The proprietors and employees of establishments have been coöperative. The policy has been one of education rather than police force. Food handlers are being instructed in the correct principles of personal hygiene and the best methods of preparation, storing, and dispensing of foods. The public is being taught to demand modern and approved methods of food sanitation. This is being accomplished through the press, radio, lectures, literature, demonstrations, and personal contact by trained personnel. The problem is a difficult one, and only a beginning has been made. Years of conscientious effort will be required to accomplish the maximum results.

CONCLUSIONS

1. Laboratory examinations have shown that a large percentage of drinking glasses used at places dispensing food and drinks in Hartford were not adequately disinfected. They were frequently found to be contaminated with bacteria from the human upper respiratory and gastrointestinal tracts.
2. Only a small percentage of places dispensing food and drinks in the city had equipment and plumbing capable of disinfecting eating utensils as required by the new Board of Health regulations.
3. Laboratory examination of glasses following the installation of apparatus capable of disinfecting eating utensils showed a marked improvement in dish washing sanitation.
4. The Inspection and Score Card adopted by the Board of Health has proved to be a valuable administrative aid as well as a stimulus to the proprietors of eating establishments to raise the standard of their service.
5. Legislation, and disinfection of equipment are of little value unless followed by an educational program for the instruction of both food handlers and the public in the correct principles of food handling.

*Supervising District Engineer, State Department of Health,
Middletown, N. Y.*

THE New York State Public Health Law, which is the legal basis for all public health work in the state, provides for the State Department of Health under direction of a commissioner, local boards of health for all political subdivisions, including cities, villages, towns and special consolidated districts, and medical health officers to serve each local health district. The Public Health Law has been amended from time to time but the general setup for health work has not changed since 1893.

The Public Health Council was established by the laws of 1913, with legislative authority to enact rules and regulations known as the State Sanitary Code. Naturally, the Sanitary Code is more flexible than the Public Health Law and is often added to or amended. Thus the local health officers are charged with enforcement of the Sanitary Code, and specific duties, including matters pertaining to environmental control of sanitation, have been materially increased in recent years by such amendments.

DEVELOPMENT OF THE DIVISION

The New York State Department of

Health is relatively old. The Division of Sanitation was created in 1906, therefore its engineering work may be classed with that of a few other states as being among the pioneer public health engineering projects of the country. On July 1, 1921, the "Division of Sanitary Engineering," with 13 engineers, was abolished and the "Division of Sanitation" created. The reorganized division had only 5 men, a director, and 4 assistant sanitarians.

The reduction of the engineering force in 1921 resulted, as I understand it, from an effort to consolidate all engineering work of the various state departments in the office of the state engineer. This might seem like a logical move to the average layman, but the value and practical necessity of the engineer in a well organized public health department is demonstrated by the growth of the Division of Sanitation in the New York State Department since 1921 to one of the most important divisions in the department. The division now includes 41 engineers and 30 milk sanitarians. The milk sanitarians are technically trained men with degrees other than engineering. Many of the present positions are made possible by funds of the Social Security Act.

While there have been some new and different activities undertaken in recent

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

years, the older reports indicate active work along the major branches of the environmental program as carried on today. The most notable development in New York State has been in the increase of personnel which has provided for a more effective control over these fundamental environmental factors.

The work in the sanitary control of milk was given additional emphasis, beginning in 1928, with the revision of Chapter III of the State Sanitary Code, requiring the approval by the state department of all pasteurizing plants. Then, in 1930, the Bureau of Milk Sanitation was created within the Division of Sanitation, this being the first bureau formed. The creation of the Bureaus of Camp Sanitation, Water Supply, and Sewage and Waste Disposal followed in 1935, 1936, and 1937. Each has provided for the concentration of effort and responsibility of the assigned personnel on these respective activities which had become a practical necessity.

ESTABLISHMENT OF DISTRICTS

With the entire personnel of the Division of Sanitation located in Albany and travelling out over the state from that point, it was difficult to exercise detailed supervision of water supply or sewage treatment plants at distant points. In addition, it was necessary for the engineer going into a community to have a thorough knowledge of the system and its history before the best assistance could be given. With different engineers going into the community, it took a great deal of additional work each time to acquire this knowledge of local conditions. The long distances, besides being costly, resulted in a rather high percentage of time spent in travel and a relatively lower percentage in productive field work. These considerations led to the assignment of an engineer to the first district in December, 1930, and, follow-

ing the successful results of the work in the pioneer or experimental districts, engineers have been assigned to cover the entire state from district offices.

The state had been divided into districts since 1914 but the personnel of the districts did not include engineers, and the activities of the districts were decidedly limited. The number of these districts has recently been increased to 19 and a more complete decentralization put into operation. Each district covers two or three counties, is under the supervision of a district state health officer, and is equipped with professional and clerical personnel of all classes necessary for the operation of an independent unit. One or more engineers are stationed in each district, and 3 senior district engineers visit the other districts in a supervisory capacity. The principle of operation of the engineering work is that the policies are established and certain supervisory and consulting services furnished by the central office, but all routine and detail work is done by the district personnel.

WATER SUPPLIES

The sanitary supervision of public water supplies was the major activity in the early days of the Division of Sanitation and today is still one of the main functions of the district engineer. The Public Health Law places the responsibility for supervision of public water supplies directly upon the State Commissioner of Health and authorizes him to order necessary improvements. The supervision is of course exercised through the engineers. Because of these provisions, the State Department has always dealt directly with the local water supply officials, with the local health officer having only a minor rôle in connection with the public water supply. Supervision by the district engineers includes periodic inspections of systems and treatment plants, review and acknowledgment of reports upon

the operation of treatments, and the promotion of desirable improvements in equipment or operations. Recently routine laboratory examinations of samples from all public systems by the Division of Laboratories and Research of the State Department have been made. The district engineers are responsible for maintaining this program and transmitting the laboratory findings.

The intimate acquaintance with the various systems within the district and with the operating personnel enables the district engineer to maintain a closer and more effective supervision over them. Many improvements in public water supplies can be credited directly to the closer relationship and concentrated effort of the district engineer. We have experienced severe floods, damaging water supply plants, in which emergencies the district engineers have proved their value and the advantage of decentralized location and operation.

SEWAGE DISPOSAL

The Public Health Law in general prohibits the discharge of sewage into the waters of the state without a permit from the State Commissioner of Health. The State Department has enforced these requirements in cases of municipalities, industrial plants, institutions and public places, and plans for satisfactory treatment plants upon which the permits may be based, are required to be submitted. These plans are checked in detail by the Bureau of Sewage and Waste Disposal and all necessary field investigations are made by the district personnel. It is now possible, through the district personnel, to get all necessary field information before passing upon the plans. The department engineers coöperate with the consulting engineers in determining the degree or type of treatment necessary or desirable and in some cases a preliminary checking of the plans is done

in the district office. The district engineers are also proving their value in promoting new sewerage systems and treatment plants and often are primarily responsible for the formation of new sewer districts.

Largely as the result of federal aid, a great number of sewage treatment plants have been constructed in the past few years. The supervision over the operation of these, including the review and acknowledgment of operation reports, is through the district offices. There is no doubt that, with the closer connection of the district engineers, this supervision is better than before and the operation of the plants as a whole more effective.

MILK CONTROL

The local health officers are made responsible by the State Sanitary Code for the milk control program, since they alone can issue permits for the sale of milk, cream, and certain milk products, and are required by the code to see to the enforcement of all regulations governing production and processing. Approval of the State Department of pasteurizing plants and "Special A Raw" dairies and bottling plants must be secured by the health officer before issuing permits for pasteurized or "Special A Raw" milk or cream. The standards for "Special A Raw" milk are in many respects equal to certified milk. By a special law enacted in 1937, all milk and cream produced outside New York State for sale within the state must be under inspection of the New York State Department of Health. About one-half the personnel of the Bureau of Milk Sanitation is engaged in this out-of-state work.

The general supervision of milk sanitation as carried on by the State Department has been turned over to district engineers and district milk sanitarians. A considerable portion of the non-engineering technical personnel of

the milk bureau is doing laboratory or research and consulting work.

A much closer supervision has been maintained over pasteurizing plants since the decentralization of the work and a great deal of help and advice is given the local health officers concerning their duties. While some local health officers have been doing a fine job of milk control work, the majority of the part-time health officers are inadequately trained and insufficiently interested to do a good job. A great deal of effort is sometimes necessary to have the health officer secure the required information on the physical condition of the cows, condition of the dairies, bacterial quality of the milk, etc., before he issues or renews permits. In some cases we know definitely that complete information is not secured. A few health officers insist on having all inspections made by their own personnel and do not accept the reports of other health officers, which they are allowed to do by code provisions. If all the inspection work of the local health departments could be properly allocated, there might be a pretty good coverage, but as it now is, this inspection work is spread too thin in some places, while in others there is none. The majority of part-time local health officers dislike routine milk work and their definite obligation in connection with it, and welcome all the assistance they can get from the State Department personnel.

The State Department program includes the routine phosphatase testing of all pasteurized milk and cream. The samples are collected by or under the supervision of the district men and the work done by the laboratories of the milk bureau. Recent results of these tests have generally demonstrated effective pasteurization. In cases where the phosphatase tests indicate ineffective pasteurization, an immediate check is made of the pas-

teurizing plant and of the general operation. Usually the reason for the unsatisfactory result is discovered and immediately corrected. In case the difficulty cannot be found in the plant and corrected, and particularly if it seems probable there has been a deliberate short holding or mixing of milk, the sale of milk from this plant is immediately discontinued. Often arrangements are made for the temporary pasteurization of such milk in another plant. The operation of the questionable plant is resumed only when assurance is given that conditions will be satisfactory.

Supervision over the production and processing of milk is one of the major activities of the engineering program today and has proved its value in the increased percentage of pasteurized milk consumed and the elimination of outbreaks of illness traceable to allegedly pasteurized milk.

SUMMER RESORTS

The proper control over summer camps, hotels, etc., is a peculiarly difficult job for health officials. Usually their season lasts for only 8 to 10 weeks and the management is loath to spend the necessary money for proper facilities. Besides this, they cannot conveniently carry on major construction work during the operating season and yet they find it inconvenient to do it at other times.

In New York State we have approximately 3,000 camps listed and have a general knowledge of thousands of hotels, boarding and rooming houses. In one county, which is a popular resort for New Yorkers, it is estimated there are 2,400 places, with a capacity for caring for 500,000 people at one time.

Chapter VII of the Sanitary Code requires a permit from the local health officer and sets forth satisfactory rules and regulations for the operation of camps. An intensive campaign for the

improvement of camps has been carried on through the district offices since the formation of the Camp Bureau and much progress has been made. Considerable pressure has been put on the local health officers to get the camps under permit; assistance has been given the health officer in making surveys of large numbers of camps and reporting upon their condition. In some cases legal advice and encouragement have been given in the conduct of proper hearings for revocation of permits and the closing of camps where serious health hazards existed.

We have no satisfactory regulations governing the operation of resort hotels, rooming or boarding houses, and this class of place presents a real problem. Many of the operators are of such character that appeal to their pride is entirely ineffective and the only possible means of securing necessary improvements, such as safe water supplies and satisfactory sewage disposal systems, is by bringing legal pressure. Correction of unsatisfactory conditions has been secured in many instances as the result of the district engineer's recommending that the local board of health take the necessary action and then closely supervising the procedure, which is usually that prescribed by the State Sanitary Code by which local boards of health may order the abatement of public health nuisances. The use of untreated surface water supplies and the discharge of sewage or sewage effluents onto the surface of the ground in accessible locations are, of course, routinely declared to be public health nuisances.

SWIMMING POOLS AND BATHING BEACHES

The Sanitary Code provides for the operation of swimming pools and bathing beaches under permit of the local health officer and sets forth standards of operation. In addition, all

plans for new artificial pools or improvements to them must be approved by the State Department and operation records maintained and submitted to the local health officer and the district office of the state. The indoor pools or those operating over a reasonable period of time each year are under very good supervision.

In the summer resort county referred to above, it is estimated there are 500 swimming pools, all of which are out-of-doors and used only during the short summer season. Our records indicate that a rather large percentage of such bathing places are operated without permit and so without supervision, even by the local health officer. In some parts of the state there is consequently a big field for missionary work by the district engineer, but additional personnel is necessary before satisfactory conditions can be developed.

ASSISTANCE TO LOCAL HEALTH OFFICIALS

The advice and assistance of the district engineer is frequently enlisted and, in most communities where local engineering service is not available, he is considered as a regular consultant to the local boards of health. This assistance is particularly sought in the preparation of new local regulations and the conduct of legal proceedings, such as hearings by the health officer for the revocation of permits or by the boards of health for abatement of nuisances. The district engineers also are of great assistance to the part-time local health officials in dealing with matters which, because of their local color, are embarrassing for them to handle.

While the local health officers have a great tendency to shift to the district engineers as much of their non-medical work as possible, they are encouraged to do better work and in some cases to undertake new activities. A decided

improvement in the control of environmental factors by local health officials has resulted from the close coöperation of the district engineers.

MISCELLANEOUS ACTIVITIES

Besides the activities mentioned, there are a great many others, the number of which is ever increasing, carried on by the engineering personnel of the department. These include investigations of nuisance complaints, stream pollution studies, supervision of real estate developments (including checking of plans of water supply and sewage disposal services), investigation of watering points of interstate carriers, reviewing monthly reports of the local health officers covering their supervision of "Special A Raw" dairies, sanitary investigation of premises in connection with F.H.A. loans, operation of new provisions of the Sanitary Code specifying qualifications for water and sewage plant operators, coöperation with New York City in inspection of questionable water supplies of milk plants serving that city, addressing clubs and other gatherings on public health engineering subjects, and assisting in the conduct of extension courses for health officers.

Many of these important activities of course could not have been attempted without increased personnel, and the strategic locations of the engineers has helped materially in the successful accomplishment of these undertakings.

The public health engineering work

in New York State has progressed steadily, at least since 1921, and it is believed the establishment of the decentralized system has been the greatest factor in this progress and in providing increased service to the people of the state. The district engineers are as so many hands of the Director of the Division of Sanitation, with the fingers stretched into every community. The population at large is becoming more conscious of environmental public health work and is asking for more and more from the Division of Sanitation.

The Sanitary Code has placed additional responsibility on the local health officers, in many cases incompatible with the remuneration received. Many of these duties are of a non-medical nature, particularly those in connection with the control of milk and of the operation of camps and swimming pools. A majority of the part-time health officers feel these obligations too much of a burden and would like to be rid of them.

A logical extension or projection of public health engineering work in New York State, in the opinion of the writer, would be to relieve the part-time local health officers of some of their non-medical functions. With engineers working in small districts, this could be accomplished by providing additional personnel and by amending the Sanitary Code to provide for this control directly by the State Department and for permits to be issued by the Commissioner through his district representatives.

A Time-Study of Morbidity and Mortality in the United States Navy*

JOHN M. WHEELIS, JR., M.D.

*Lieutenant, Medical Corps, U. S. Navy, Washington, D. C.
In charge, Vital Statistics, Bureau of Medicine and Surgery,
Navy Department*

THIS paper is a preliminary report of research being done with morbidity and mortality records of the United States Navy. It deals principally with technic and basic data. The work is still in progress and only a partial report of results can be given at this time.

Unusual opportunities for research are offered by our data. The procedures for reporting sickness from the field are well defined and long established. The reports cover about 130,000 persons and come from all ships and stations of the Navy. When doing research in Washington, one may rightly consider that he has as field workers the 800 medical officers and a portion of the 3,700 hospital corpsmen of the Navy.

Regulations require that anyone not fit for duty at the time of morning sick call be placed on the sick list. Any disability of more than 24 hours' duration therefore becomes a matter of record and is reported directly to the Section of Vital Statistics in the Bureau of Medicine and Surgery.

These reports, though brief, contain all necessary data for complete identification of the individual and of his disability, including the number of sick days. These are known as Individual Statistical Report(s) of Patient(s). After having been edited and placed individually on tabulating cards, they become the most important single item in the medical statistics of the Navy. Although they are intended primarily for routine use, they are on file for past years and are available for research. They were used in the present study.

The purpose of this study is to determine what happens to persons as they enter the Navy and grow older in it. This defines *Length of Service* as the basic variable. To provide a more homogeneous group and greater statistical continuity, only the enlisted personnel of the Navy were studied. Naval officers, officers and men of the Marine Corps, nurses, midshipmen, and prisoners were excluded. The period of the study is the calendar years 1935 and 1936. About 175,000 person-years are represented.

Description of the population in terms of the basic variable involved considerable detail and some interesting methods.

In the Statistical Section of the Bureau of Navigation there is main-

Submitted concurrently to the *U. S. Naval Med. Bull.* for publication.

NOTE: The statements herein presented emanate from the author, not from the Navy Department.

tained a living file of naval personnel. It consists of a tabulating card for each man. At the end of each year these cards are checked individually with the annual census from the field. Annually the numbers of personnel, by 4 year length-of-service groups, are reported. For the purposes of this study, the 4 year group was considered satisfactory for those with 4 years' service and over. It was considered necessary, however, to split up the under 4 year group much more finely. This was done by a life table method as will be described.

A man enlisting in January, 1931, would just complete 4 years' service in January, 1935, the first month of this study. In order to describe the under 4 year group completely for the years 1935 and 1936, it was necessary to follow, during their first 4 years' service, all men enlisting from January, 1931, to December, 1936, inclusive. The number enlisting each month during this time was obtained. Since these were derived from daily reports as received in the mails, they were adjusted for an average, 5 day, postal lag. Each of these groups was then followed separately by identifying, in the dead files, the cards of those who failed to survive their first 4 years' service, that is, the cards of those who left the service within their first 4 years. This produced 72 different survivorship records, beginning with successive months of enlistment, and ending with completion of 4 years' service or with the end of the study. After aligning them in stairstep fashion so that contemporary groups were side by side, it was easy to combine in any monthly grouping desired, during any calendar month of the study. The counts so obtained were adjusted arithmetically to the 15th of each month.

Monthly population figures for each of the groups with over 4 years' service were computed arithmetically from the counts as reported annually. Then,

for each of the 24 months of the study, figures were recorded for 13 length-of-service groups, as follows: less than 1 month; 1 month; 2 months; 3-5 months; 6-11 months; 1 year; 2 years; 3 years; 4-7 years; 8-11 years; 12-15 years; 16-19 years; and 20 years and over. Then, by re-combining these groups, totals were obtained for comparison with known monthly totals supplied by the Bureau of Navigation. The latter had also to be adjusted for a 5 day postal lag and from the last to the 15th day of each month. The range of error in the 24 totals was from 0.03 to 0.67 per cent and the average error was 0.20 per cent. These errors were adjusted.

A man may be taken up on the sick list in the Navy in any one of 5 different ways. A (new admission); ACD (a first admission for a condition which complicates, or follows as a sequel of, a contributory disability); EPTE (a first admission for a disability which existed prior to entry into the service); RA (a readmission for a disability previously taken up by any one of the 3 preceding methods); or, REM (remaining from the previous year). The sum of the first 3, A, ACD, and EPTE, represents the total number of first admissions. All 5 must be considered to determine the number of sick days.

Among other things, length of service and date of admission are shown on each sickness card. Through mechanical sorting and tabulation the data were arranged for recording on basic tables, one for each disability, or group of disabilities, considered. The numbers of first admissions were recorded in each length-of-service group during each of the 24 months.

The numbers of sick days were also distributed along the length-of-service and time variables. The technic for this was rather complicated but the results should be interesting since the

numbers of sick days represent the actual time lost due to sickness and are, along with mortality rates, the final measure of the effect of sickness in terms of loss of man power.

This work is being done in phases. The first is the communicable diseases, the second the acute respiratory diseases. One would expect close relation of the first to environment. Information is greatly needed about the second.

This report deals with the communicable diseases. They are loosely defined here as the single attack, droplet-transmitted, acute, specific infections. There were 2,899 such cases distributed as shown in Table I.

As men come into the service they arrive from all parts of the country. Some are from cities and have had frequent and diverse contacts with other people. Some are from rural areas where their contact rate was low. During the period of this study about 1,200 new men entered the service each month.

These new men are placed in one of

TABLE I

Distribution of Cases

German measles	1,132

Ac. ant. poliomyelitis	3
Total	2,899

4 training stations for their first 3 months' service. They undergo a common experience and are together in groups nearly all of the time. Although their new environment is well controlled and healthful, they are, nevertheless, epidemiologically crowded. Most of them are more crowded than they had been in civilian life. Probably very few are any less crowded. Upon completion of 3 months' training most of them leave for other ships and stations. Some remain for further training. In addition to these new men there are a certain number of older

Fig. 1. COMMUNICABLE DISEASES, ENLISTED PERSONNEL, U.S. NAVY, 1935 & 1936.

men at the training stations who act as instructors. After leaving the training stations, the new men intermingle with men of all lengths of service and gradually, themselves, grow older in the service.

From the foregoing it can be seen that this study is concerned with more than just the military aspects of changing length of service. We might say that we have a fixed experiment in human epidemiology. Our "herd," so to speak, is the enlisted personnel of the Navy. There is a constant flow of individuals into and out of the "herd." The new ones are placed in a "cage," the training stations. A certain number remain for as long as 7 months but most of them leave the "cage" after 3 months to mingle with the main "herd." A smaller number of the older members of the main "herd" return to the "cage" and are in contact with the new individuals. Having exact data on these movements of in-

dividuals and on associated morbidity and mortality, we can study them closely from the experimental epidemiological viewpoint.

We find that, upon combining the 2 years' experience, the person-years were distributed as shown in Table II. The numbers of communicable diseases were as shown in the third column, and the annual rates in the last column resulted. When the rates are put in diagrammatic form they produce the picture shown in Figure I. The solid bars represent our rates and the cross-hatched ones show age-specific rates taken from the report by Collins¹ of the incidence among 9,000 white families in 18 states surveyed during 1928-1931. Exact comparison of these two sets of rates is not attempted. The civilian rates are included merely as a physical basis for associative comparison. The average age at enlistment was 20.01 years. Age and length of service are necessarily closely correlated.

On this basis the civilian rates for the ages of 20 to 25 were considered to cover ages of men with from 0 to 5 years of service.

TABLE II

Person-Years and Numbers of Cases According to Length of Service

Length of Service	No. Person Years	No. Cases	Ann. Rate per 1,000
Less than			
1 month	2,492	129	51.77
1 month	2,427	399	164.40
2 months	2,455	424	172.71
3-5 months	7,209	321	44.53
6-11 months	13,654	255	18.68
1 year	21,707	363	16.72
2 years	14,293	253	17.70
3 years	10,000	167	16.70
4-7 years	36,686	315	8.59
8-11 years	27,871	146	5.24
12-15 years	22,983	80	3.48
16-19 years	13,545	44	3.25
20 years and over	991	3	3.03
Total	176,313	2,899	16.44

During the first month the annual rate of communicable disease incidence

is 51.8 per 1,000. During the next 2 months it rises to 172.7. This peak rate, for a group of men slightly over 20 years of age, is the same as that observed by Collins among children $9\frac{1}{2}$ or 10 years of age. The initial rise of incidence is steep and the subsequent drop precipitous. Within 2 months it drops to one-fourth of the peak rate, within 6 months to one-eighth, and within a year to one-tenth. It would be difficult to assume that these rapid changes in incidence are due to changing calendar age. That they are associated with changing environment and adaptation to it seems much more likely.

Seasonal factors are important in the incidence of these diseases. The seasonal curve for the entire group is shown in Figure II. The peak is in February and the trough is in October. The peak rate is about 10 times the trough rate.

TABLE III

*Monthly Incidence of Communicable Diseases by Length-of-Service Groups, Enlisted Personnel, U. S. Navy, 1935 and 1936 Combined **
Annual Rates per 1,000

	0-2 Months' Service	3-5 Months' Service	6-11 Months' Service	1 Year's Service and Over	Totals
January	213.77	48.31	19.86	11.08	22.84
February	498.00	79.73	33.66	18.36	41.98
March	200.33	107.83	37.75	18.57	31.17
April	209.83	85.03	36.77	16.92	27.89
May	156.58	45.87	20.13	14.53	21.04
June	145.90	40.97	17.30	6.81	14.29
July	105.92	25.93	19.41	6.69	12.76
August	43.63	34.91	12.06	3.71	7.23
September	46.55	18.17	8.63	4.22	7.06
October	9.99	10.70	5.31	3.50	4.24
November	17.98	10.29	3.89	3.98	4.88
December	24.82	14.27	10.40	4.65	6.36
Totals	129.09	44.49	18.68	9.32	16.44

* January, for example, represents the combined experience of January, 1935, and January, 1936.

It becomes of interest to know how the different length-of-service groups react to seasonal influences.

For convenience of the diagram and because the groups shown in Figure III are representative, the 13 length-of-service groups were combined into 4 as follows: 0-2 mos., 3-5 mos., 6-11 mos., and 1 year and over. Just as was expected from Figure I, the groups with less service have the higher incidence. Only in two instances do any two curves meet, and these are at trough levels. Also, the seasonal peaks flatten

out as length of service increases. In order to get away from absolute numbers and to examine more closely the proportional variations of the lower curves, the same seasonal rates were plotted on an arithlog scale in Figure IV.

Eighteen months are shown in order to avoid breaking the seasonal cycles. Each month represents the combined, corresponding months of the 2 years. For example, the January rate shown here represents both January, 1935, and January, 1936. The rates are on an

Fig. 4. COMMUNICABLE DISEASES BY LENGTH OF SERVICE
ENLISTED PERSONNEL, U.S. NAVY, 1935 & 1936 COMBINED.

annual basis. On the arithlog scale the flattening of seasonal peaks is still apparent. The ratio of peak to trough decreases as length of service increases. In ascending order of the 4 length-of-service groups, the ratios are 50:1, 10.5:1, 9.9:1, and 5.3:1. As length of service increases the peak tends to come later in the season. In Figure IV the abscissal scale is shown somewhat out of proportion in order to bring out this point.

No attempt is being made at the present time to draw conclusions from the facts which have been presented. Many more approaches are planned. Cook² observed that men entering the service during the fall and winter months suffer a much higher incidence of cerebrospinal fever during their first year than those entering during the spring and summer. It will be of interest to know to what extent this holds true for any or all of the other

communicable diseases and to split up the phenomenon by single calendar months of enlistment. It will also be of interest from both epidemiological and military points of view to know whether these differences during the first year are equalized during later years.

Throughout all of this work the training station population and rates can be separated from the others for comparison. It will be of particular interest to know the results of application of these methods to the acute respiratory diseases. Sick days, mortality, and fatality will also be analyzed in the same way.

*Assistant Surgeon General, U. S. Public Health Service,
Washington, D. C.*

A WEEK seldom passes in which a request is not received by the Public Health Service from someone for a statement of progress made under the Social Security Act. As might be supposed, a large proportion of such inquiries come from members of the Congress; many come from students of sociology and government in colleges and universities, from women's study groups, research agencies, and magazines carrying both professional and popular articles.

It would seem a simple matter to write a report each year which could be printed and passed out in routine fashion that would serve current demands. Unfortunately this is not possible, since each request is more or less individualistic in the variety and combination of data for which it calls. With few exceptions, therefore, each inquiry must be handled from a separate viewpoint. Although the furnishing of this material in response to the various shades and varieties of demands becomes an irksome task, it is one which must be regarded rather in the light of an opportunity, since those who seek information become the mouthpieces

for spreading the message of accomplishment through the enlarged facilities which have been placed at our disposal.

A resumé of progress necessarily connotes a comparison of some kind. It would be fortunate indeed if there were some simple and reliable yardstick by which progress could be accurately gauged. Most desirable of all would be a precise measurement of the number of lives saved, the illness prevented, health and happiness promoted, and economic saving accomplished. It is believed, however, that the unequivocal answer to these questions will never be entirely satisfactorily determined on a quantitative basis. Failing in this, one turns next to a measurement of activities, extent of organization, enumeration of recruits to the public health personnel, and the amount of money spent in the extension of health service. Of this group of criteria the most significant is the activity record, though this is to a very large degree deceptive and unreliable as a means of evaluation of progress. In like manner the personnel employed and the health machinery established may be looked upon not as yardsticks of accomplishment, but as corroborative evidence only. Of all the indices of progress, the one most readily available and subject to accurate measurement is the amount of money

* Read before the Western Branch American Public Health Association at the Ninth Annual Meeting in Portland, Ore., June 6-8, 1938.

spent for public health work. The natural tendency, therefore, in estimating public health progress, is to resort to a listing of funds made available for health work, though in fact this is one of the least significant standards.

In an effort to portray the health progress made under the Social Security Act it will be understood that only the roughest sort of an estimation can be made by the use of any and all of the factors, whose limitations have been briefly pointed out. At best the tangible evidences of public health dividends are immediately discernible only in isolated instances. Occasionally some dramatic example of life saving or sickness prevention is observed. But public health expenditures must be looked upon as long term investments founded on faith in the efficacy of public health methods which are believed to be sound. Just as the horticulturist plants a tree knowing full well that he will have to wait several years for the harvest of fruit, so the public health worker must be reconciled to look for the full fruition of his labors within the next decade or possibly within the next generation. For the present, therefore, the report of progress must deal with evidences of means to the end rather than the end itself.

The Social Security Act is now well advanced on its third year of operation. Since the passage of the Social Security Act the maximum amount of money authorized has been appropriated each year. When it became effective in February, 1936, health organizations generally were at a low ebb. They had suffered heavily from reduction of funds in the economy wave associated with the general financial stringency. Many essential health services were crippled or discontinued because of the loss of personnel; and the morale of many of those who remained was sadly impaired as a result of drastic salary reductions.

The funds appropriated under Title VI of the Social Security Act brought welcome relief from these straitened conditions. A considerable portion of the Social Security funds was utilized to repair the breaches in the public health structure that had been created by the economic slump. After having done this, the state health authorities turned their attention next to expansion of existing health services and the addition of new activities.

One of the most significant outgrowths of the program under Title VI has been the movement toward higher standards for public health personnel. At the meeting of the State and Territorial Health Officers in 1936, qualification specifications were adopted with the view to eliminating the unfit from the ranks of public health service. Although these standards were not compulsory, they placed upon the state health officers a moral obligation to abide by them. The bane of the conscientious health administrator's hopes and ambitions has always been pressure from political influences for the employment of incompetent political favorites. Without recourse to qualification standards as a condition of employment the state health officers would have been hopelessly swamped with job seekers whose only claim for consideration was allegiance to some person or party. While this set of qualification standards was a life-saver to health administrators, it was also a two-edged sword. The state health officers found themselves suddenly in possession of greatly increased funds, and were confronted with the problem of how to use these funds in accordance with the personnel policy to which they had subscribed.

Trained personnel to fill new positions was almost wholly lacking. Although funds were made available for the training of personnel, it takes time to locate and select suitable trainees, and more time still to give the tech-

nical training. To meet this latter emergency, short or semester courses at training centers were instituted.

In both state and local health programs the personnel problem was a serious handicap in the beginning. In addition to this the local health program has been and continues to be in many localities retarded by the lack of local organization. It is generally conceded that local full-time health units wherever consistent with state laws and policies are the very backbone of a state-wide health program. Local health units, however, call for local appropriations to be pooled with funds from outside sources. It takes time, energy, and initiative to sell health units to local appropriating agencies. Even in those states where this work was vigorously undertaken, the time interval necessary for the consummation of local health budgets resulted in an accumulation of funds in state allotments which must remain unpaid until such time as budgets should be submitted for the operation of these projects.

The limitations which have been pointed out with respect to personnel and local programs account for the surpluses that accumulated during the initial stages of the operation of Title VI of the Social Security Act. At the end of the first 5 months, June 30, 1936, there was an accumulation of \$881,000 out of a total appropriation of \$3,333,000 for that period. At the end of the fiscal year 1937 (June 30), the surplus was \$1,116,000. The indications are that at the close of the fiscal year 1938 (June 30), the surplus will not exceed \$200,000. In each instance the surplus has been added to the appropriation for the ensuing fiscal year, and reallocated to the states. It is obvious from the foregoing that the expansion of health services has been stepped up to a level almost commensurate with the funds available. In fact, the machinery which has been de-

veloped now exceeds the facilities for maintenance at its present level, so that either more state and/or local funds will have to be secured in certain states, or activities will have to be curtailed.

As you probably know, the regulations governing the payment of funds from Title VI to the states specify certain matching requirements. Of special interest is the requirement which calls for the appropriation of new funds for public health work. The belief that this requirement has been effective in stimulating increased state and local appropriations is strongly supported by the figures indicating the excess of appropriations since the passage of the Social Security Act over the previous level. According to the latest data which were tabulated about a year ago this excess was estimated at that time to be at least \$7,500,000. Undoubtedly this figure has been materially augmented during the year following this tabulation.

How the states have invested the funds paid them from Title VI will be of interest as an indicator of the activities which are being most prominently featured. The following tabulation shows a general classification of purposes for which the sum of \$10,304,663.50 was budgeted by the states for the fiscal year 1938.

Prior to the inauguration of the Social Security program, 667 counties in the United States were listed as being served by full-time health officers. The number of counties so served as of December 31, 1937, was 1,166, from which it would appear that there has been an increase of 74.8 per cent in the number of counties under full-time direction, more or less directly as a result of aid extended through Title VI of the Social Security Act. There are 6 states completely covered by local full-time health service as compared with 3 on January 1, 1935. In spite of these highly encouraging facts, however,

PURPOSES FOR WHICH ALLOTMENTS TO STATES FROM FUNDS APPROPRIATED UNDER THE PROVISIONS OF SECTION 601, SOCIAL SECURITY ACT, FOR THE FISCAL YEAR 1938, WERE BUDGETED, TOGETHER WITH AMOUNTS THEREOF, AS OF JANUARY 1, 1938

<i>Purpose</i>	<i>No. of States</i>	<i>Amount</i>
Local Health Services	45	\$4,219,935.79
Training of Public Health Workers	51	1,485,467.29
Venereal Disease Control	43	827,325.56
Sanitary Engineering	44	539,559.52
Promotion and Supervision of Local Health Services	36	527,821.00
Laboratory Research	41	412,086.09
General Administrative Expenses	48	372,109.53
General Preventable Disease Activities	38	362,453.19
Industrial Hygiene	21	355,654.21
Tuberculosis Control	25	280,641.50
Vital Statistics	32	161,149.14
Public Health Nursing	21	144,370.00
Malaria Control	9	129,323.00
Health Education	23	112,613.00
Pneumonia Control	4	85,099.68
Dental Hygiene	8	70,615.00
Rodent Plague Control	5	58,748.00
Food and Drug Inspection	5	54,895.00
Trachoma Control	5	34,263.00
Cancer Control	5	29,614.00
Maternal and Child Health	7	25,540.00
Mental Hygiene	1	15,380.00
	Total *	\$10,304,663.50

* Includes unexpended balances

there are still 10 states which have no local health service corresponding to the generally accepted standards implied by this term.

The stimulation of a new interest in industrial hygiene activities in state health departments has been particularly noticeable—funds allotted to this work having increased from approximately \$30,000 prior to 1936 to well over \$300,000 for the current year, and the number of states engaged in this work has increased from 3 to 23.

There has also been evident in the South a renewed interest in state health department facilities for malaria control.

The tremendous wave of public interest and enthusiasm in the campaign against syphilis speaks for itself and needs little comment here.

One of the most interesting developments in the program has been the increase in public health nursing service.

Between 1931 and 1937 the total number of public health nurses employed by local and state health agencies in the United States increased from approximately 16,000 to 18,000. This represented an increase of 22.3 per cent in nurses employed by official agencies and a decrease of 7 per cent in the number employed by nonofficial organizations. The most significant change has been noted with respect to rural areas, where there has been an increase of 32 per cent in the number of nurses since 1931.

Most of you are familiar with the program for training state and local public health personnel which was inaugurated in 1936 under the provisions of Title VI of the Social Security Act. It may be of interest to you to know that nearly 3,000 individuals had been given special postgraduate training in public health work up to June 30, 1937, and that during the current fiscal year

PRESCHOOL HYGIENE		
Individuals admitted to medical service (E 8)	144,449
Individuals admitted to nursing service (E 9)	259,653
Visits to medical conferences (E 10)	191,959

the number receiving training will be in the neighborhood of 1,300. Among those who have received training are 651 medical officers, 162 engineers, 1,540 nurses, 451 sanitation officers, 88 laboratory workers, and 60 others. More than 200 medical officers will have received a full 1 year course in public health administration at the close of the current year, and 161 nurses will have been given a whole year of postgraduate work.

It is impossible to devise any reporting system that will accurately record all services performed by local health units. Even the most extensive report forms will not do this. It is, however, incumbent upon the Public Health Service to secure some record of activi-

ties carried on with Social Security funds. For this purpose an extremely abridged report consolidated for all local health services employing Title VI funds within a state is required quarterly, with the view to securing a representative cross-section of work performed. There is herewith presented the consolidated report from all the states for the fiscal year 1937, which will serve to convey some idea of the volume of local health work in progress.

It should be noted, of course, that this work is financed only in part (roughly 50 per cent) by Social Security funds.

If public health is to pursue a course of progress its program should be readily adjustable to varying needs and circumstances. Local problems are en-

countered in some states which are non-existent in others; problems common to all states require in some states a heavier weighting in the health program than is given in others. The advancement of basic scientific knowledge, changing public sentiment, and changing social conditions are ever introducing new problems to which the public health program must be adjusted. For these reasons a progressive public health program is flexible, and responsive to new ideas. In this connection I would invite your attention particularly to some of the broader phases of public health responsibility. In the address of Josephine Roche, Assistant Secretary of the Treasury, at the meeting of the American Public Health Association in New York, she clearly defined one of

the most urgent issues in the following language:

The challenge which confronts public health workers today is in essence the same as that which confronted the great leaders of the past when human life was wiped out by epidemics and infectious diseases. The objective for which they strove is identically the same as yours today—to save life, conserve health, to prevent death and disease. So, as I stated earlier, you take on no new function when you turn to new ways and means to meet this unchanging objective. You only face the fact that your battle in the laboratory to find and conquer the causes of destructive diseases, and in the field to apply this knowledge, must not only be continued but widened and extended to the social and economic front. Death and disease are no less your responsibility to prevent because the cause for them has shifted, demanding care of the individual by public means when that individual's economic status makes im-

possible his securing for himself medical care and facilities necessary for saving life or health.

An appraisal of progress in public health service under the Social Security Act must take into account the degree to which public health workers have attuned themselves to the opportunities

for life saving, by whatever means, in the future. This question can be answered only by each one of you individually. The future destiny of public health as a factor in our social structure will depend in a large way upon the intelligence and courage with which this challenge is met.

Annual Roll Call November 11-24, 1938

Fleas as Vectors of Plague*

C. R. ESKEY, M.D.

*Senior Surgeon, U. S. Public Health Service Laboratory,
San Francisco, Calif.*

IT is now well established that fleas are capable of transmitting plague from one host to another. Innumerable species of these parasites have been found on animals throughout the world. Over 80 species have been collected from wild rodents in our western states and new ones are being discovered every year.

As a rule one species of animal seldom acts as the natural host for more than 3 or 4 species of fleas in the same locality, and sometimes for only one. Some varieties of fleas may naturally infest several species of animals, but usually such hosts belong to the same generic group. A few, like the sand flea, appear to utilize almost any animal as their normal host. When different kinds of animals live in close association or come in contact with each other, fleas peculiar to one may be found on others that are not their usual hosts. That fleas may subsist for long periods on blood of animals foreign to them has been demonstrated in the laboratory by keeping many different wild rodent fleas alive for 2 to over 5 months when fed on guinea pigs.

Animals that continually live in the same nesting place, as is usually the case of those dwelling in burrows, harbor more fleas than those that use their nests only for rearing their young.

When ground squirrel nests are excavated during the summer, one may see enormous numbers of larvae wiggling about in them, and it is often possible to collect many adult fleas from the nests. Therefore, in determining the extent of the flea infestation of rodents, one must take into consideration the insects that are present in the nesting places as well as those found on the animals.

Climatic conditions play such an active part in determining the prevalence of fleas infesting domestic rodents that in some localities having unfavorable climates there are insufficient vectors to cause plague epizootics. The potential danger of plague becoming established among wild rodents of any region has little relationship to its climate, being chiefly dependent upon the kind of rodents present and the extent of their population, because wild rodent fleas are as acclimated to their environment as are their wild hosts.

Experimental transmission of plague by fleas—The usual procedure followed in testing the ability of fleas to transmit plague by placing them on an infected rodent, then, after its death, allowing the exposed parasites to infest another animal, provides very little information regarding plague infection of fleas. Positive results obtained from such experiments might be due to infected flea feces rather than to the bites of the insects.

* Read before the Western Branch American Public Health Association at the Ninth Annual Meeting in Portland, Ore., June 6-8, 1938.

During the past 2 years experiments have been conducted at the Public Health Service Laboratory in San Francisco in which approximately 1,200 fleas have been tested individually; that is, each flea has been kept in a test tube from the time it was collected until its death. This method provides exact knowledge regarding the time that fleas become plague infected; the period that elapses before they transmit the disease; the length of time the insects survive infection; and, the identity of each flea can be ascertained after its death. Plague infection of living fleas can be determined by inoculation of their feces, and of dead fleas by injecting their bodies into guinea pigs.

Infesting fleas with plague—From the literature on plague one might gain the impression that a flea which has fed at any time on an infected animal might transmit the disease. In reality there is only a short time before death from acute plague that there are sufficient organisms in the blood to infect fleas. The blood of guinea pigs has not been infectious to fleas earlier than 36 hours before death and it is probable that fleas are not infected by the blood of other rodents over a longer time. During this short interval before death the degree of septicemia varies greatly in different guinea pigs. *Pasturella pestis* may be found in every microscopic field of the blood smears of some acutely sick animals, while in others, blood cultures are required to demonstrate the organisms. As would be expected from the results of blood examinations, the percentage of fleas infected experimentally after feeding on different animals has varied greatly. In most cases only a very small number of fleas have been infected even when the blood examination demonstrated that it contained many organisms, and in no instance has it been possible to infect all fleas fed on one animal. In view of these observations it may be stated

that when plague infected animals are killed during the early stages of the disease, or before the development of septicemia, none of the fleas on the animal will have been infected by its blood. Furthermore, even when animals have died of plague, only a small percentage of the fleas on the dead hosts are liable to be plague infected, because only a portion of the fleas that have fed during the septicemic period will be infected, and some fleas do not feed often enough to have ingested blood at this time.

It is doubtful whether fleas ever become infected by feeding on sick animals that recover from acute illness, or that have mild sub-acute infections. In one instance during the experiments at San Francisco a large number of fleas were fed daily for 3 days on a guinea pig that appeared to be so ill each day that it would die in a few hours, and then it began to show signs of improvement which went on to complete recovery. None of the parasites that fed on this animal were infected and blood cultures made during the 3 days of acute illness remained sterile. This guinea pig was inoculated again with plague and recovered a second time.

Multiplication of Pasturella pestis in fleas—During the act of feeding, blood passes through the esophagus into the proventriculus, and then through a short tubular structure into the stomach proper. The blood is stored during digestion in both the proventriculus and stomach so that ingested bacteria may multiply and form clumps in either organ. More than one mass may be present in the stomach and remain discrete for a long time or coalesce with the formation of one large growth. The rapidity with which the masses grow varies greatly in different fleas. In some only small clumps are present after two or more months, while very rapid growth may occur with extension of the masses into the proventriculus.

In many instances the stomachs are greatly distorted in shape and size by the bacterial growths and have a rather characteristic appearance, being contracted into a more or less tubular form with jagged margins.

Bacterial growths in the proventriculus produce great enlargement of this structure and nearly always extend forward into the esophagus, causing it to be distorted and dilated. Whether or not the masses formed by *P. pestis* develop primarily in the proventriculus or invade it from the stomach, the end results are the same, leading eventually to partial, and then complete obstruction of the esophagus. This blockage has been observed to occur as early as 4 days after plague infection, or it may not develop until several months after ingestion of *P. pestis*. In the case of a number of fleas killed over 3 and 4 months after infection there were no visible masses in the proventriculus and only small bacterial growths were seen in their stomachs.

The dark brown masses formed by the multiplication of *P. pestis* in fleas are not solid clumps of viable organisms but are composed chiefly of colloidal-like material so adhesive that the masses can usually be dissected out intact, and require rough handling to tear them apart. In stained specimens coccobacilli are found in large numbers on the surface of the growths, on the adjacent membranes of the stomach, and in any fluid that may be present.

Transmission of plague by flea bites

—From such information as one may obtain from textbooks it would seem that when a host is bitten by a plague infected flea infection will naturally follow the bite. This idea is further from the truth than the belief that all fleas which have fed on an infected animal will be carriers of plague. In San Francisco over 300 fleas have been infected, and they have fed several thousand times and still their bites have

not been infectious. There were individual infected fleas that fed from 50 to 100 times on guinea pigs without transmitting plague. Less than 10 per cent of wild rodent fleas acted as vectors in the laboratory, indicating that in nature only a very small percentage of fleas which have fed on infected wild rodents will really infect other animals by their bites.

As long as the bacterial masses do not prevent the passage of ingested blood into the stomach the bites of plague infected fleas are harmless. It is only after development of obstruction to the flow of blood and regurgitation which carries the organisms into the wound occurs that the bites of fleas are infectious. In the course of experiments fleas have transmitted plague as early as 5 days and as late as 147 days after they had ingested *P. pestis*.

Normal fleas of nearly all species seldom insert their proboscides more than once and satisfy their hunger in less than 5 minutes, while the efforts of blocked fleas to feed are often characterized by prolonged exertions to secure blood in one place, or by shifting from one site to another, until they apparently become exhausted. Sometimes a tiny drop of regurgitated blood exudes from the proboscis of an obstructed flea when it is withdrawn from the skin. Many fleas with complete obstruction of the esophagus fail to transmit plague regardless of how prolonged their exertions to feed have been. This may be due to the fact that the blocked fleas are too weak for their efforts to cause regurgitation, or the organisms are not detached from the bacterial growths to be carried into the wounds. After death the obstruction of the esophagus is easily seen with the microscope and frequently fresh red blood is visible in the esophagus in front of the obstructing mass.

Period fleas are infectious—Very few infected fleas survived more than 24

to 48 hours after there were indications that there was an obstruction to the flow of the blood meal to the stomach, regardless of whether or not their attempts to feed were infectious. Of the 45 fleas which transmitted plague in the laboratory only about 20 per cent infected more than one animal, although some of those that failed to cause multiple transmissions attempted to feed after they had infected one guinea pig. Five fleas infected 3 to 5 guinea pigs and one infected 10 animals. This latter flea and one that infected 5 animals transmitted the infection for 5 and 10 days respectively. The infectious life of these 2 fleas was exceptionally long because most blocked fleas live only a short time and few of them are capable of infecting more than one host before they die.

Transmission by male and female fleas—Although many male fleas of different species were used in the laboratory experiments, only 2 of the 45 that transmitted plague were males, which is rather conclusive evidence that female fleas are much better vectors than males.

Plague infection of different species of fleas—During the experiments in San Francisco it has been possible to demonstrate plague infection of 20 different species of fleas, 15 of which were collected from wild rodents, 3 from domestic rats, and 2 miscellaneous fleas. Of the different species found to be plague infected only 11 transmitted the infection to guinea pigs. Domestic rats, prairie dogs, chipmunks, and several varieties of ground squirrels acted as the natural hosts of the fleas which were vectors of plague in the laboratory. Failure to obtain experimental transmission with certain species of fleas does not prove that they are incapable of acting as transmitting agents. In fact the results of laboratory investigation tend to indicate that any flea, regardless of species, that feeds on

septicemic blood may become plague infected, and later blockage of the esophagus may occur which would make the flea a potential vector.

Although there is a possibility that all fleas may act as transmitting agents of plague, epidemiological data and laboratory studies clearly demonstrate that the rat fleas, *Xenopsylla cheopis*, are much more active and dangerous vectors of plague than any others tested. A second species of rat fleas, *Nosopsyllus fasciatus*, was found to be as capable of transmitting plague as any of the wild rodent fleas. Some species of fleas seem to be very feeble vectors.

When compared with all other species studied, *Xenopsylla cheopis* are considered the most efficient transmitting agents because they are more readily infected when fed on septicemic blood, and they transmitted the disease to many more guinea pigs. They also tend to become blocked earlier and to remain infectious for a longer time than other fleas. Blocked cheopis are very persistent in their efforts to obtain blood and in many instances they produced 2 to 5 foci of infection on the abdomen of guinea pigs where they had made wounds in their attempts to feed. Some cheopis appear to be capable of infecting guinea pigs every time they insert their proboscides. Multiple foci of infection rarely followed the bites of any fleas except cheopis.

The average length of life of plague infected *Xenopsylla cheopis* is less than 1 month due to the early involvement of their proventriculus by the bacterial growth. Many cheopis did not survive infection 2 weeks, and the longest that any of them lived was about 50 days, while many infected fleas from wild rodents and the rat fleas *Nosopsyllus fasciatus* remained alive from 2 to over 4 months before they became blocked and died.

If different species of fleas do not have the same ability to transmit

plague, and if the infection persists much longer in some species than others, it may be assumed that the character of plague epizootics will vary according to the kinds of fleas involved in its dissemination. For instance, an epizootic in a community where *Xenopsylla cheopis* are prevalent should be much more severe and accompanied by a greater incidence of human infection than would be the case in a locality where the spread of the infection depended on one or more of the other species of fleas studied in the laboratory. On the other hand, in regions where cheopis are the only rodent fleas present to maintain an epizootic, and conditions arise which tend to cause the disease to subside in rodents, so that its continuation depends upon the persistence of the infection in fleas the epizootic would be more likely to disappear than would be the case if other fleas were present, such as *Nosopsyllus fasciatus*, which may remain infected for a much longer time than cheopis. Wild rodent fleas may remain infected for several months so that it is possible for plague infection to be carried over the hibernating period of wild rodents in fleas.

Plague infection of flea feces—Virulent plague bacilli can be demonstrated in the feces of nearly all plague infected fleas by inoculation into guinea pigs. Some species of fleas do not excrete virulent organisms as constantly as others. The length of time fleas have been infected does not affect the virulence of the bacteria in their feces. In some cases the inoculation of excreta collected at the time fleas have died has produced plague in guinea pigs when injection of the fleas gave negative results.

Since Bacot and Martin demonstrated that fleas transmit plague when feeding, the old idea that transmission followed rubbing infected feces into minute wounds has been more or less

discarded. However, it is possible that plague is disseminated among rodents much more frequently through the agency of infectious feces than is generally believed. It is difficult to understand how rodents escape infection in this manner when we consider that one or more infected fleas may live for several months on their hosts and during this time continually deposit large numbers of virulent plague organisms in the fur and on the skin of rodents which will cause infection if rubbed into minute abrasions. It is not necessary for the infectious feces to gain entrance to the hosts' bodies immediately after they have been deposited in order to induce infection because recent experiments conducted at San Francisco have shown that *P. pestis* may retain its virulence as long as 4 weeks in dried flea feces kept at room temperature.

It is unlikely that humans contract bubonic plague through the agency of flea feces because rodent fleas do not remain with human hosts for a very long time and there is slight chance for them to deposit feces on the skin of man. Fleas rarely defecate when feeding and the lesions of rodent fleas seldom cause itching.

Tendency of rodent fleas to attack man—It has been known for many years that domestic rat fleas often bite man, but there is little knowledge regarding the facility with which wild rodent fleas will attack humans. From the fact that 6 different species of sylvan fleas—or all that have been tested in sufficient numbers at the laboratory in San Francisco—have been found to feed on human blood, it may be assumed that many species of wild rodent fleas will bite man. In one instance 18 fleas were collected from a ground squirrel nest shipped to the laboratory and each flea as captured was placed on the arm of one of the workers with the result that 17 of them fed almost as soon as they touched the

skin. It has been possible to keep several kinds of wild rodent fleas alive for a number of days by feeding them on human blood, but others of the same species died of starvation before they would feed on man. Our observations have shown that all rodent fleas have to be starved to a greater extent before they will accept human blood than is required for them to feed on rodents that are not their natural hosts. Many fleas that have refused to bite man were found to feed at once when placed on rats or guinea pigs. From these findings it would appear that starved, blocked, plague infected fleas of wild rodents may attack man when they come in contact with the skin so that there is danger of humans contracting bubonic plague in all regions where wild rodents are infected.

CONCLUSION

Twenty different species of fleas have been infected with plague in the laboratory but only 11 species, 9 of which were collected from wild rodents, transmitted the disease to guinea pigs; only

a portion of fleas fed on plague infected guinea pigs a few hours before the animals died were infected, and of those infected only a small percentage transmitted plague to other guinea pigs. Flea bites are not infectious until the masses formed by *P. pestis* cause obstruction of the esophagus. This condition may develop in a few days or not for over 4 months. Few fleas ever infect more than one animal and blocked, infectious fleas generally die within 48 hours of the time there is evidence of obstruction to their stomachs.

Infected fleas are constantly excreting virulent coccobacilli in their feces which may survive for as long as 4 weeks in the dried excreta so that rodents are exposed to infection from the feces as well as the bites of fleas.

There is always a possibility of humans contracting bubonic plague from blocked fleas present on wild rodents in regions where sylvatic plague exists, but these fleas are not nearly so dangerous to man as the domestic rat fleas, *Xenopsylla cheopis*.

Tenure of Office for Health Officers*

JOSEPH W. MOUNTIN, M.D., F.A.P.H.A., AND
ELLIOTT H. PENNELL

*Senior Surgeon, and Associate Statistician, U. S. Public Health
Service, Washington, D. C.*

FROM groups concerned with health organization often come assertions to the effect that health officials as a class occupy positions where tenure is insecure and of short duration. If such statements be true and generally applicable, public health administration faces a serious problem. There is little hope of professionalizing a position where constant turn-over is the rule; neither can a community expect effective service from a health department that operates under shifting management. Strange as it may seem, these commonly held notions of instability with respect to tenure of office appear to have developed from limited observations or general impressions; a careful search of the literature failed to disclose any comprehensive analysis of the situation based on the actual employment records of persons who had served in the capacity of health officer. Under the circumstances it seemed appropriate to study in a quantitative way the experience of health officers, using as source material such recorded information as may be available.

The employment records used for this study are taken from the directories† of state, county, and city health officers published annually by the U. S. Public

Health Service. Supplemental information in respect to age and professional degrees was taken from directories of physicians published by the American Medical Association, and from lists of members published by the American Public Health Association. In the directories of health officers are enumerated all state health officers, health officers of cities containing 10,000 or more inhabitants, and officers in charge of county health departments. The names of village and township health officers and of county physicians are not included in these publications. Appearance or nonappearance of a name in the directories of health officers is accepted as the criterion of employment. This method introduces some degree of error because of the vagaries of reporting, but the resulting discrepancies do not distort the picture in any appreciable degree. It must be understood that disappearance of a name from the registers does not necessarily signify that the person has abandoned public health as a profession; he may continue to occupy some position other than administrative head of a tax supported health department listed in the specified directories. No doubt a few died in office, but information for correcting the data on this point was not readily avail-

* From Division of Public Health Methods, National Institute of Health. Read before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

† Periods covered by these directories are: State 1912-1935, city 1916-1935, county 1922-1935. County data for period 1908-1921 taken from *Public Health Bulletin* 222.

TABLE I

Distribution of Health Officers According to Total Full-time Employment Experience and Status at Close of Study (1935)

<i>Employment Status at Close of Study</i>	<i>Total Health Officers</i>	<i>Accumulated Years of Employment</i>	<i>Average Years of Employment</i>
Still employed	793	6,186	7.8
Out of office	1,591	5,730	3.6
Total	2,384	11,916	5.0

able; here too it is believed that the inherent error is of little moment.

Part-time service has been excluded from the more detailed analyses since data on individuals so employed are rather fragmentary; furthermore, progress in public health organization is believed to be more intimately tied up with the fate of full-time employees than of those who regard health administration as a subordinate occupation. It was also deemed advisable to exclude from consideration persons whose names appeared only in the health officer directories for the last year of study. These health officers, though on active duty, had not completed a full year of service; hence their experience was not adapted to the categories used for this analysis.

In the data presented through this report are represented the employment histories of 2,384 full-time health officers who by health jurisdictions are distributed as follows: state 127, city

982, county 967, and 308 who served in more than one type of jurisdiction. The total employment period may be expressed as 11,916 health-officer years, and the average period as 5 years (see Table I). At the close of 1935, the last year of study, 1,591 health officers were no longer in office, while 793 still retained their positions. For the former group the average period of employment was 3.6 years, and for the latter it was 7.8. Among the discontinued group about 50 per cent had completed their experience in 2 years or less, and nearly 75 per cent served less than 5 years (Table II). For the group in office at the close of the study the corresponding percentages were much better, being roughly 12 and 33. In the zone of long-term employment periods the relative performance of the two groups is very similar; about 10 per cent of the group with completed experience served 9 years or more, while 35 per cent of those in office at the close of the study had been there for a similar period. The same material is presented graphically in Figure I by means of the median and interquartile range.

For the group no longer in office at the close of the study the employment period, as expressed by a median, is 2.4, and for those still employed it is 6.7. The configuration of the curves and the range of the middle 50 per

cent also serve to illustrate the differences in employment pattern of the two groups. This behavior suggests a high rate of discontinuance early in the employment history of health officers, while those who weather the elimination process tend to continue as chief administrators for a considerable period of time. There is no way from our basic data of determining the extent to which early separation is voluntary and how much is due to failure of the person to secure reemployment.

To measure completed service is a rather simple matter since the dates of entrance on duty and of termination of employment are known. On the other hand, there is no basis for predicting how long a person employed at the end of the study period might continue to fill the office. In order that all health administrators may be judged on a comparable basis with respect to their retention of position, a period extending

from the date of entrance on duty into the last year of study (1935) was taken to represent the available period of employment. Health officers were then classified on the ratio of their actual years of employment to the total available period. For example, a person who became health officer in 1929- might have continued for 6 years; if he remained 3 years he would have completed only 50 per cent of the available period. Stability of positions expressed as the ratio of actual to available years of service (Table III) is presented graphically in Figure II. Taken together health officers classed as having from 2 to 4 years of available employment served during more than 70 per cent of it; those with from 5 to 8 years of available employment were in office nearly 60 per cent of the period, while the ones that had 9 or more years during which they might be employed actually were reported in office less than

FIGURE II—Distribution of health officers according to available years of full-time service and the proportion of available years served by health officers in the several groups

45 per cent of the available period. It is to be expected, of course, that the proportion of actual to available years of employment should grow less as the period of possible service lengthens. However, the relatively good showing made by the small group who took up full-time work early, clearly demonstrates that discontinuance is not a simple straight line function of length of employment. In this connection it is well to recall the data presented in Table II; there it was shown that there is a tendency for health officers either to drop out of the directories after a short period of service or to continue in the capacity of chief executive over a considerable span of years.

The period of part-time employment was recorded for 311 health officers who also had full-time service. By adding the two periods, the average employment experience of the in-service group having both full- and part-time health officer service would be increased by 67 per cent; and for the discontinued group the corresponding percentage increase would be 80.

From the foregoing data and other points that might readily be adduced it becomes apparent that health officers

behave quite differently with respect to their period of employment. This suggests the possibility that some factors common to a significant number of individuals may account for these differences in employment pattern. The information at hand, though fragmentary, covers such points as date of birth, age when first appointed, and professional degrees of the health officer; while relative to place of employment source material pertains to type of health jurisdiction and its geographic location. Even though the findings are not altogether conclusive, there are associations between different circum-

* Information on age of health officers was limited to physicians whose ages were listed in American Medical Directory.

stances that appear worthy of presentation. In this connection it should be recalled that full-time service is a relatively new departure in most health jurisdictions. At the close of the study only a small proportion of what promises to be a stable group of officials had completed their employment experience; hence the effect of this group on the mass is obscured when the years of service for health officers in various categories are reduced to a mathematical expression.

While it is true that persons in office at the close of the study period show much better performance with respect to total years of employment and proportion of actual to available years, yet the two groups react quite similarly to the influences on employment that have been selected for study. Because of this circumstance and the necessity for simplicity in presentation, both groups have been combined and their behavior is reviewed from the standpoint of length of employment. This period is expressed by the use of a median and the range of the middle 50 per cent. The factors under consideration are divided into two classes: those listed in Table IV are inherent characteristics of health officers, and those in Table V pertain to the jurisdictions where the health officers are employed.

The health officers whose manner of listing in the directories would indicate special training that led to a professional degree present employment records of duration considerably below those without such attainments; the median for the former group being 3.4 and for the latter 4.1. While the figures are impressive, this difference may have little meaning since difficulty was encountered in classifying training from the information at hand; furthermore there is reason to believe that the directories were both deficient and inconsistent on this point.

Age was studied for its possible effect on length of employment. By using 45 years as the critical point, it was found that those above showed a median period of 3.9 years, and those below, 3.4. This small difference is hardly sufficient to suggest that age is any great factor. The slightly better showing of those in the older group may be due to their having had an opportunity to accumulate more years of full-time service than those who were unable to qualify for positions until recent years. Clearly, persons who accept positions in two or more health jurisdictions are likely to accumulate additional years of employment above those who remain in one place. The median years of employment for the migratory health officers

TABLE V

Median Years and Interquartile Range in Full-time Employment for Health Officers Serving Jurisdictions Having Different Characteristics

<i>Characteristics of Jurisdictions</i>	<i>Total Health Officers</i>	<i>Years of Experience</i>	
		<i>Median</i>	<i>Interquartile Range</i>
Type of jurisdiction			
State	127	4.3	2.4- 8.1
County	967	3.0	1.4- 5.6
City	982	3.0	1.5- 6.5
Combinations	308	6.8	3.8-11.3
Location			
New England, Middle Atlantic	490	3.6	2.0- 8.8
South Atlantic, E. South Central, W. South Central	1,115	3.5	1.5- 6.5
East North Central, West North Central	544	3.4	1.5- 6.5
Mountain, Pacific	235	3.1	1.4- 6.3

is 6.0 and for the stationary ones it is 2.9. Migration, however, is not an outstanding characteristic of health officers as a class since only 431 moved, while 1,953 completed their recorded experience in one place. Most of this limited experience was reported by county health officers.

The region where a health officer is employed seems to exert as much if not more influence on his tenure as do those personal qualities which are discernible from data that describe the group under consideration. In studying the possible effect of circumstances surrounding employment, one finds slight geographic differences. Health officers employed in the Mountain and Pacific areas show a period of employment shorter than is the case for other sections of the country. The median years of employment in the areas used for this study are as follows: New England-Middle Atlantic 3.6; South Atlantic-East South Central-West South Central 3.5; East North Central-West North Central 3.4; Mountain-Pacific 3.1. The difference in performance between the Mountain-

Pacific group and the remainder of the country, while of a low order, may be accepted as having some statistical significance.

Health officers of cities and counties show the shortest period of employment with a median of 3.0 years. The position of state health officer is somewhat more stable and represents a median period of 4.3 years, or more than 1 full year above that reported for county and city health officers. Health officers who secure successive employment in more than one type of health jurisdiction lengthen their period of service to a median of 6.8 years. This longer experience is in accord with the observation previously noted that health officers who change their location thereby increase their years of employment.

It is entirely possible that opportunity for accumulating years of full-time service in jurisdictions of one type as contrasted with another may explain differences in periods of employment. The establishment of full-time positions for health officers in a sig-

nificant proportion of counties is a rather recent innovation; cities seem to have been slow in changing from part- to full-time service, while the position of state health officer has in most instances been on a full-time basis for a number of years.

When health officers as incumbents in jurisdictions of different governmental types are distributed according to years of employment (Table VI), one finds an unusually high proportion of city and county incumbents that served 1 or 2 years. If appraised on this criterion, state health officers do much better; yet one-fourth of them fail to serve more than 2 years. On using 5 years as a critical point it was found that the percentages of health officers by type of jurisdiction who served 5 years or more are as follows: states 47, counties 33, cities 35. Only 12 per cent of the health officers who shift from one type of jurisdiction to another serve less than 3 years, while 68 per cent serve more than 4 years.

Within their respective categories health jurisdictions behave differently in the security accorded to those who occupy the position of health officer. In some places there is little turn-over among the incumbents, while in others a change of health officers is made every few years. An analysis of the behavior of jurisdictions as expressed by their employment policy is not within

the scope of this study, *Ohio* possession, *paper*. Data in our that *jurisdictions* however, show very clearly *vidis* jurisdictions are essentially *indiv*ualistic in this respect. It would seem that traditions of government, coupled perhaps with chance, influence the treatment of health officers much more than any clear-cut employment policy.

SUMMARY

Data presented in the foregoing article substantiate in considerable measure the prevailing impression that full-time health officers as a class pursue this type of work for relatively short periods of time. A generalization which expresses average experience, however, cannot be applied to all health officers. There is an unstable group constituting about 40 per cent of the total who are discontinued as full-time employees within 2 years from their first listing in the directories. After this critical period is passed the performance of those who remain is very much better. Particularly significant is the point that nearly 40 per cent of health officers had 5 or more years of full-time service while 18 per cent remained in office for 9 years or more. A very large proportion of the longer term health officers were on duty at the close of the study period, hence have the opportunity for improving still further their employment record.

Longer periods of service are reported for health officers who accept positions in two or more jurisdictions than for those who complete their experience where first employed. Neither personal factors such as age and technical training, nor geographic location of the health jurisdiction seemed to affect in any great measure the period of employment. State health officers presented somewhat better records than

did those of other jurisdictions, but this performance is probably due to the fact that states preceded both cities and counties in establishing a high proportion of full-time positions.

Taken as a whole the outlook for reasonable tenure of position for full-time health officers is not all that may be desired; yet the situation is much better than it is commonly alleged to be.

Population Growth—Its Vital Statistics and Public Health Aspects*

WARREN S. THOMPSON

Scripps Foundation, Miami University, Oxford, Ohio

THE facts regarding the present growth of population in the United States are too well known to this group to need much elaboration here. The birth rate has been declining for a number of decades, but as long as the death rate declined almost as fast—in fact at times even faster—the slackening of the birth rate did not attract a great deal of attention because the rate of natural increase was not greatly affected. Then, too, except for relatively short periods at different times, the large inflow of the foreign born added materially to our increase decade by decade, both because of the net gain through immigration itself and because of the relatively high birth rates of these foreign born. Furthermore, it is not unlikely that the very size of our decennial increase in numbers since 1900—13 to 17 millions—led us to overlook the fact that the rate of natural increase was declining rather rapidly.

In any event, within a little more than a decade there has been a marked enhancement of interest in the natural increase of our population and a growing realization that changes of far-

reaching significance are taking place. It is common knowledge today that even though there is still a considerable excess of births over deaths (800,000 to 900,000) each year, this excess persists only by virtue of the favorable age composition which is a heritage of the large natural increase of the not distant past. Because we had an increasing number of births each year until 1921–1925, we will have more persons in the child-bearing ages for some years yet than we had in the past, so that even with declining specific rates the total number of births will remain higher than the number of deaths for perhaps two decades. This same age make-up is also favorable to a low death rate and a relatively small total number of deaths. When, however, this favorable age make-up has passed, the crude birth rate will decline significantly even though specific birth rates should remain as they now are, and crude death rates will rise until they approach or even surpass those of a life table population. With specific rates for both births and deaths as they are now, we will have an actual excess of deaths over births and a declining population within about three decades. Further decline in specific birth rates will, of course, hasten the approach of the time when deaths will exceed births.

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

It is to be expected that death rates will decline somewhat in the future; but even if the expectation of life should rise to 70 years, which is 8 or 9 years higher than it now is, the death rate of a life table population would be 14.3 per 1,000, which is about 30 per cent above the present crude rate and only about one-sixth below the present crude birth rate.

From the standpoint of our interest here, it is the age changes which are taking place as our population growth declines that are of primary importance. The Scripps Foundation has calculated what our future age composition will be, if specific birth rates and death rates decline certain given amounts in the future, and if there is no appreciable immigration. It will not be possible here to do more than cite the main changes which would take place on the basis of what we regard as the most probable movements in vital rates.

The one thing that is reasonably certain is that the age changes indicated will not be exactly realized. On the other hand, it seems reasonably certain that the proportions of the population actually in the different age groups will not depart so greatly from these calculations that general conclusions derived from them will be useless.

In 1930 the persons under 20 constituted 39.2 per cent of our total population; by 1960, only 22 years hence, they will make up only 29.3 per cent. This is a decline of almost one-fourth. The group in the childbearing ages (20-44), on the other hand, will change but little during this period—from 38.1 per cent in 1930 to 37.4 per cent in 1960. The proportion at the ages 35-44 will, however, increase while that of the younger ages, when women are most fertile, will decrease. Thus the 35-44 group will increase from 13.9 per cent of the total population in 1930 to 15.4 per cent in 1960, while

those 20-29 will decrease from 16.8 per cent in 1930 to 14.3 per cent in 1960. This change in the age of the childbearing population is even more striking if we consider only the women 20-44. In 1930 the women 20-29 constituted 44.8 per cent of all women 20-44, but by 1960 they will constitute only 38.0 per cent of this group. On the other hand, the women 35-44 will increase from 35.7 per cent in 1930 to 41.5 per cent in 1960. Clearly, with the same specific birth rates in 1960 as in 1930, there will be a marked decline in the crude birth rates. There will also be a marked decline in the total number of births. This is the most important effect of the foreseeable changes in the age make-up of the group 20-44.

The increase in the proportion of the population at ages over 45 is of special interest because of its effects on the general death rate and because of the changes in public health work needed to adapt it to serve these older groups adequately. In 1930, the middle-aged—45 to 64—constituted 17.4 per cent of our people; in 1960 they will make up 23.3 per cent. The numerical increase in this age group between 1930 and 1960 will be about three-fifths while the total population will increase by only one-fifth. It is in the group 65 and over, however, that the most striking increase will take place. In 1930 this group constituted only 5.4 per cent of our total population, but in 1960 it will constitute 10.0 per cent. In actual numbers it will increase from about 6.5 millions to about 14.5 millions.

It would indeed be carrying coals to Newcastle to dwell at any length upon the effects of such age changes on the general death rate. Only a very great drop in the death rates at the older ages can prevent a rise of 40 per cent or more in the present crude rate, *i.e.*, a rise from the present rate of about 11 to 15 or 16 as our actual age com-

position approaches that of a life table population.*

Perhaps it will assist us to appreciate the public health problems involved in attempting to keep the general death rate from rising more than 25 or 30 per cent above the present level if we will study the changes in the expectation of life as shown in the life tables of some of the more progressive countries during the last century. These life tables without exception show a large and gratifying rise in the expectation of life at time of birth. In the United States, we can get a pretty good notion of the changes in the expectation of life in the period since 1789 if we use the life tables for Massachusetts.

In 1789 in Massachusetts a new-born boy had an expectation of life of 34.5 years. This rose rather slowly for about a century, and in 1890 was 42.5 years. From then on it rose rapidly and in 1930 was about 59 years. At age 20, on the other hand, the increase in expectation of life during this 140 year period was only about 11 or 12 years, and most of this apparently took place before 1890, although since 1900 about 4 years have been added to the expectation of life of males aged 20. This may be compared with the 12 or 13 years that have been added to that of new-born boys since the latter date. At age 40 the expectation of life of males has changed only from 25.2 years in 1789 to 29.0 in 1930—a gain of only a little over 3 years. At age 60 there

has not only been no gain, but there has actually been a slight decrease—from 14.8 to 14.3.

In England and Wales there has been much the same change although the period for which data are available is not so long. In 1838–1854 the expectation of life of boys at birth was 39.9 and this rose to 58.7 in 1930–1932. At age 20 the figures are 39.5 and 46.8 respectively; at age 40 they are 26.1 and 29.6, and at age 60 they are 13.5 and 14.4.

In the Scandinavian countries, the pattern of change is the same as in the United States and England, but at the older ages, the expectation of life has improved more than in most other lands—for example, in Sweden it rose from 12.1 years for males at age 60 in 1816–1840 to 16.5 years in 1926–1930.

In New Zealand, where the expectation of life is the highest of any country in the world, the increase for males between 1896–1903 and 1931 was 10.6 years at birth but only 1.3 years at age 60. Thus it appears that there has been only a relatively small increase in the expectation of life at ages of 40 and over even when we can go back a century or more, while there has been a very large increase at birth and up to age 20.

These facts show beyond doubt that all the great advances in medicine and in public health work during the last century have had but small effect in prolonging the life of the mature adult. They have, however, done much for the new-born infant and for young children.

It is possible that the very success of health work in saving the lives of infants and children is one of the reasons it has not accomplished more for the adult. It may be that the survivors to adulthood today are not, on the average, as tough, not as resistant to organic ailments, as the survivors in a population having more rigorous selection at the younger ages. So far as

* It should be pointed out that the only figure of much doubt in the above calculations is that for persons under 20. These persons are not yet born and the birth rates used in calculating their numbers may vary more or less from those actually realized. I may say that the birth rates used here seem likely to give a larger number of births than the actual rather than the reverse. As for the other ages, all persons who will be over 22 in 1960 are already born. There may be large fluctuations in the death rates from which survivors are calculated, but since this is not very likely, we can be reasonably sure of the numbers at these ages. The proportions at the different ages would of course be affected by a larger or smaller number of births than that calculated.

I can see there is no means of testing the validity of such a hypothesis because one cannot tell who among those now 40 or over would have survived under the health conditions prevailing a century ago. However, the most important reason for the failure to effect any considerable increase in the expectation of life of the mature adult undoubtedly lies in the difference in the nature of the ailments to which children and adults are subject. Children are subject to germ diseases rather than to organic diseases. Their organs have not had time to go astray or to fail in their proper functioning, but the introduction of alien organisms—germs—catches their bodies unaware, so to speak, and easily overcomes their feeble resistance. Hence the development of sanitary living conditions and the protection against a few of the more virulent germ diseases have wrought wonders in reducing infant and child mortality.

But these measures do not suffice to prolong to anything like the same extent the lives of those who have survived childhood. The body apparently builds up a certain amount of resistance to these germ diseases if it survives their early attacks, but this does not in any way insure against the wearing out of our vital organs. There is a limit beyond which our bodies cannot be kept in good working order. There is little reason to think that we have already reached this limit in the United States since in New Zealand and in Sweden the expectation of life at age 40 was about 3 years greater in 1931 than it was in the United States, and at age 60 was about 1.5 years greater.

Due to the differences in the types of diseases which cause death among infants and children and older people, the improvement of the expectation of life among the latter will probably be much more difficult. The category of diseases labeled infectious and para-

sitic cause, about one-sixth of all the deaths of children under 5 years of age but only about one-twenty-fourth of the deaths in the slightly smaller group of persons 60 and over. On the other hand, cancers and other tumors are negligible as causes of death among children under 5, but account for nearly 13 per cent of all deaths among people over 60. Diseases of the circulatory system are also of small moment among children but cause almost 40 per cent of all deaths at over 60 years of age. Diseases of the nervous system also take a heavy toll among old people but are of little moment among children. Diseases of the respiratory system and of the digestive system take a heavy toll among both young and old but especially among the young.

This very brief statement shows clearly that in general the diseases which account for a large part of the deaths among the older people are those arising from or associated with the wearing out of the vital organs. In the very nature of the case these diseases have no such uniform and simple causes as have typhoid, diphtheria, enteritis, measles, etc. Sanitation, care to avoid exposure, and antitoxin inoculation will not ward off many of the diseases of later middle age and old age. Their causes are far more complicated than the causes of diseases which claim the lives of infants and children. Also they are probably highly individual so that treatment that will prevent heart ailment in one person may not prevent it in another. Then, too, social conditions very difficult of amelioration probably more often lie at the root of organic diseases than of the more acute infectious diseases. Thus the conditions of one's living and of one's work, which are very intimately bound up with the entire social and economic structure, may be the underlying causes of the breakdown of the heart, the kidneys, the liver, or the develop-

ment of nervous troubles rather than any specific bodily condition or infection. It is very difficult, indeed it is almost impossible in most cases, to establish any demonstrable nexus between the immediate cause of death and the conditions of life which may have induced this particular ailment. Furthermore, even when it is known that a particular organic disease is likely to result from a given manner of life, this knowledge does not throw any significant light on how to apply effective means of prevention in this and similar cases since it may be quite impossible for the victim to comply with the conditions essential to his health because of economic or social conditions over which neither he nor his physician has any appreciable control.

Only a much more extended community control over economic and social conditions than we now have, coupled with an enlarged and more adequately organized public health service, can make available to everyone the full benefits of our growing medical knowledge. But since these organic ailments do not seem to endanger the entire community like a contaminated water supply or the spread of smallpox and diphtheria, they are not now generally considered matters of public concern except by a small minority of those practising medicine and a few persons whose work leads them to appreciate the difficulties the average person has in securing adequate health service. I venture to predict, however, that there will be a very rapid extension of public health work within the next two or three decades and that the diseases of later middle life and old age will receive a much larger share of attention in the future than in the past. But we should not expect too much in the way of prolonged life from better health service. The human organism has its limits and must wear out. What we may expect is that life will be made

more comfortable and more pleasant for older people by keeping them in reasonably good health until near the end of life.

By way of summary I would again call attention to two points which stand out clearly from a study of present-day death rates and the trends in mortality: (a) there is need of a greater concentration on the study of organic diseases in the medical schools and research organizations than in the past, and (b) it seems highly probable that medical men will have to join forces with sociologists, economists, and the government much more than in the past if they are to search out all the causes of the ailments of adults and find the means for their prevention and cure—for example, even more than in the prevention of infectious diseases, it may be necessary to exercise control over the general conditions of life if organic ailments are to be prevented from taking an unnecessary toll.

As officials interested in public health work, you have never believed that health was solely or even primarily a private matter which could be left to physician and patient. You are fully aware that securing a sanitary water supply is quite beyond the means of an individual in any densely settled community. Just so it seems that taking care of organic troubles is very frequently beyond the power of physician and patient alone. The community must provide the social and economic conditions in which physician and patient can coöperate effectively. In other words, public health organization must be extended into new fields to bring the full benefits of medical discovery into play for our aging population, just as it was necessary to create an effective public health service in the past century to apply the knowledge of medicine and sanitation which had been accumulating but which could not become effective in reducing human misery

until it was organized by the community. If such an extension of public health service as is envisaged here is objected to on the ground that it encroaches on the freedom of medical practice and the right of the individual to determine what he will do with his own health, the answer is that long ago the community determined that no one had a right to spread smallpox or diphtheria or certain other diseases; indeed in some communities one has no right to have these diseases at all but must be immunized against them. Today we are on the verge of saying, as they have already done in Sweden, that no one has a right to have venereal disease and certainly no one has a right to marry and have children as long as there is danger of transmission. Tomorrow we may come to prize more highly the right to proper medical examination and diagnosis looking to the prevention and early cure of organic ailments than the right to have circulatory troubles, nephritis, or diabetes if we want to.

If the extension of public health service to the point where everyone has adequate health service curtails freedom in certain respects it will, on the other hand, create a far more valuable freedom, namely, the freedom from crippling and lethal organic ailments in an increasing portion of our population, and this surely is a consummation devoutly to be wished for.

Every great advance in human welfare has been regarded as revolutionary by those whose interests were adversely affected, but once the step has been taken and the benefit realized, future generations wonder why their forebears were so stupid as not to have done it sooner. So it will be with the extension of public health service and the economic changes necessary to make advancing medical knowledge fully effective for human welfare. But such an extension of health service will come and it will be organized to care for the older part of our population much more adequately than in the past.

Practical Experience with the Scharer Rapid Field Test for Pasteurization*

D. M. ROGER

Borden's Farm Products, New York, N. Y.

THE efforts expended by workers in Public Health and commercial dairy laboratories in the control of the pasteurization of dairy products together with recent improvements in equipment and effective Board of Health regulations have considerably increased the efficiency of pasteurization. Unfortunately frailties, human and mechanical, still exist causing the slight inefficiencies in pasteurization that would be almost impossible to detect had the phosphatase test not been developed.

As is generally known by workers in this field, the enzyme phosphatase which is present in mixed supplies of cows' milk, has the ability to hydrolize disodium phenyl phosphate liberating free phenol, a quantitative determination of the phenol liberated being a measure of the activity of the enzyme. When milk is held at pasteurizing temperatures phosphatase is almost completely inactivated by the end of the holding period. It has been demonstrated by Kay and Graham³ and others²⁻⁷ that a measurement of the phosphatase activity of pasteurized milk is an index of the efficiency of pasteurization.

Gilcreas and Davis² in their investigation of the Kay and Graham test not only demonstrated the value of the

test but also awoke a nation-wide interest in the subject. While the Kay and Graham method is suitable for use in a well equipped laboratory it does not lend itself to routine plant control and field work.

The ideal test for plant control must embody simplicity, rapidity, and reasonable accuracy. For plant control it is not necessary to measure the exact degree of under-pasteurization—it is sufficient to know if a sample will or will not pass as being efficiently pasteurized.

Fortunately for those of us employed in the control of pasteurization plants, Scharer⁴ of the New York City Department of Health has developed two modifications of the Kay and Graham test, one for laboratory work involving an incubation period of 1 hour and the other a rapid field test requiring only 10 minutes' incubation. The reagents for this rapid test may be made up according to directions given by Scharer⁵ or they may be purchased on the market in tablet form, which is very convenient for control and field work.

EXPERIENCE WITH THE TEST IN PLANT CONTROL

About a year ago it became evident that the best method of controlling pasteurization by means of the phosphatase test was to equip each plant so that the milk could be tested at

* Read at a Joint Session of the Laboratory, Public Health Engineering and Food and Nutrition Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October, 28, 1938.

regular intervals during the run. The Scharer Field Test filled most of the requirements previously mentioned and preliminary tests indicated that it would detect at least 0.5 per cent added raw mixed milk. Knowing that this test was new and not fully tried out we installed it in 14 pasteurizing plants and awaited further developments. During the past year, in these plants and the laboratory, we have performed more than 18,000 tests by this method or a slight modification of it. While these findings have not the same value that tests on samples pasteurized under laboratory conditions would, certain observations may be made:

1. No cases were encountered where interfering substances in the milk itself gave false positive tests.
2. Duplicate tests checked accurately where reasonable care was observed.
3. It has been possible to detect the addition of 0.1 per cent of raw mixed milk to milk pasteurized commercially at 143° F. Such tests were made frequently to check the reagents. (In plant work we have always used a 30 minute incubation period for the test.)
4. When samples from these plants were run side by side in the laboratory and one or two plants consistently gave higher readings than the others it seemed safe to assume that unless there were interfering substances in the milk, this was an indication of some fault in the pasteurizing process rather than an error in the test. Follow-up inspections of these plants have usually revealed the reason for these higher tests, but the intermittent occurrence of only slightly abnormal tests is not so easily explained, but if these intermittent tests are confined to one plant it is again safe to assume that the pasteurizing is at fault and not the test.
5. If accurate work is to be done the precautions given by Scharer⁵ regarding the storage, preparation and checking of the reagents must be strictly adhered to.

SOME CAUSES OF FALSE AND ERRATIC TESTS ENCOUNTERED

Scharer has listed certain causes for false tests in his article.⁵

The most common causes of false positive tests that we encountered were:

1. The equipment used for sampling had been contaminated with raw milk.
2. The tablets used for preparing the test solutions were too old or had not been kept under refrigeration.
3. The test equipment had not been properly cleaned.

Some less common causes were:

1. One case was found where someone had dipped a pipette contaminated with raw milk, into the bottle of distilled water used for making up the substrate.
2. Some reagent bottle closures have been encountered that liberated phenol.
3. In another case someone had contaminated the distilled water, with sulphuric acid from a storage battery hydrometer. While this did not cause a positive test it did interfere by retarding the development of the indophenol blue.

Some causes of erratic tests:

1. Insufficient mixing of the milk with the substrate at the start of the test.
2. Insufficient shaking after the B. Q. C. indicator has been added.
3. Not waiting full 5 minutes after the B. Q. C. indicator has been added.
4. Insufficient shaking when extracting with the butyl alcohol.

Most of the work that we have done has involved the use of amyl alcohol* (boiling range 126—132° C.) as a solvent in place of normal butyl alcohol. While the amyl alcohol does not extract quite so much of the indophenol blue it has the advantage of not extracting so much of the yellow color from high color milk and cream. This yellow color does interfere with tests on slightly under-pasteurized products. However, for most practical purposes butyl alcohol is satisfactory.

Since many of our plant testers work by artificial light it is important to develop a distinct color contrast between a pasteurized milk test and a test on a sample that is slightly under-pasteur-

* Different color standards are required when amyl alcohol is used.

ized. To accomplish this we have equipped our plants with small water bath incubators and have increased the time of incubation from 10 to 30 minutes. Table I indicates the color gain achieved by this increased incubation.

TABLE I

Holding Time and Temperature		Incubation	
Minutes	Degrees F.	10 Minutes	30 Minutes
25	142	B	B
30	142	5+	5++
35	142	2+	5+
25	143	2+	5+
30	143	2—	2—
35	143	2—	2—

The color standards used are those described by Scharer.⁵ Normal butyl alcohol was used for extraction.
B indicates that a blue color was easily detected without extraction. (With experience one is able to pick out even smaller discrepancies without the alcoholic extraction.)

It will be noted in Table I that, fortunately, pasteurized samples show little increase in color due to increased incubation but slightly under-pasteurized samples show considerable gain.
Table II shows the results of tests on some samples of "B" Raw milk pasteurized under laboratory conditions.

TABLE II

Time of Holding	Temperature of Holding $\pm 0.2^{\circ}$ F.				
Minutes	141° F.	142° F.	143° F.	144° F.	145° F.
20	B	B	B	5	2—
25	B	B	5+	2	2—
30	B	5++	2—	2—	2—
35	B	5+	2—	2—	2—
40	B	5	2—	2—	2—

These samples were incubated 30 minutes at 37° C. The same color standards were used as in Table I. Normal butyl alcohol was used for extraction.
Table III indicates that there is little or no benefit to be gained by incubating 30 minutes at 47°C. instead of 37°C. In our plant control work we incubate our samples in small insulated water baths which are filled with water at

44°C. at the end of 30 minutes the temperature is still above 37°C. Table III indicates that this range of temperature should not interfere with the test.

TABLE III

A Comparison of Duplicate Tests Incubated at 37° and 47° C. for 30 Minutes

Sample	Reading After 30 Mins. Incubation			
	At 37° C.		At 47° C.	
1	2	2	2	2
2	2—	2—	2—	2—
3	5	5	5	5
4	5+	5+	5+	5+
5	2	2	2+	2+

Normal butyl alcohol was used for extraction and Scharer⁵ color standards were used to obtain the readings in this table.

SUMMARY

A year's experience with the Scharer Rapid Field Test has shown that this method is simple, and when performed with care its accuracy closely approaches that of the longer laboratory tests.
A 30 minute incubation period was found to aid in the detection of slightly under-pasteurized samples.
When this test is used as a routine control the milk and cream can be checked before leaving the plant.

Health Maintenance in Industry*

CLARENCE D. SELBY, M.D., F.A.P.H.A.

Medical Consultant, General Motors Corporation, Detroit, Mich.

THE workman in industry is employed about 25 per cent of his time. It is only in this respect and to that extent that his life differs from that which is common to his community and the position he occupies in it. The causes of sickness and injury may originate at any time during the 24 hour cycle of each day. Some are definitely occupational, some are definitely non-occupational, and in some, the origin may be doubtful.

The definitely occupational are responsible for about 6 per cent of the workman's total annual disability from sickness and injury. In other words, 25 per cent of his time, or his occupation, accounts for only 6 per cent of his annual disablement. This clearly places the major problem of maintaining employee health in the employee himself and his community rather than in the plant, and it immediately brings up the question—What can the plant physician do about it?

He can do this. He already has a well organized health maintenance program which experience is proving to be effective in so far as the occupational disablements are concerned. He can extend this program to include studies of non-occupational sickness. He can act as a case finding agency for the local private physicians who care for the workman, and he can act as an aid to the local health officer.

It is doubtless unnecessary to discuss the plant physician's health maintenance program which is now fairly well established and rather well known, but as a basis for consideration of these newer responsibilities, it should at least be outlined.

OCCUPATIONAL DISABLEMENTS

The treatment of industrial injuries and occupational diseases is assumed in any industrial medical program. Every well organized plant medical service has ample provisions for that. It can be said, however, that the modern plant physician is coming to depend more and more upon specialists for services of that nature. He is himself a specialist in a field which is gradually merging into preventive medicine, and he recognizes the value of specialized attention in the treatment of injuries and uses it.

Unfortunately this is the only service that the employees of about 85 per cent of the industrial establishments of the United States receive and it involves about 60 per cent of the employed population. To render adequate service, comparable with the best practices of industrial medicine, to this group, is a problem of the private practitioner in medicine who serves industry on-call or on a part-time basis, and its solution lies in their training for industrial practice.

In connection with the handling of the occupational disabilities, the plant doctor is occasionally faced with the necessity of passing upon the validity

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

of claims for compensation. His decisions, whether large or small amounts are involved, are always important because of their possible influence upon employee relations. He must not, however, be influenced by this fact or by the fact that he is employed by the management. A partisan plant doctor cannot for long hold the confidence of either management or the employee group.

The treatment of occupational disabilities is still a major function of industrial medicine, and in many places it is the dominant function. If partisanship is pursued to the point where the doctor becomes known for his bias, he is seldom competent to protect either his company or the health of the workmen. An effective health maintenance program in particular is built up on confidence. The plant physician is always on sound ground when he gives his employee patients the consideration he would if they were private patients, and in this all they ask is that he be fair.

With the exception of the treatment of occupational disabilities, all functions of industrial medicine point up toward health maintenance. A logical beginning is in studies of the working environment.

ENVIRONMENT

Theoretically a physician is able to determine the effects of environment upon health, but practically only those can do so who are familiar with the plants in which they serve, and then only by studies of the various operations and workroom environments, by special examinations of the workmen, and the coördination of all findings. This is a task of magnitude, especially with regard to studies out in the plant.

To assist him in these, the doctor now has a valuable ally in the industrial hygienist. Ability to interpret his findings is essential and capacity to obtain

corrective measures is desirable. Otherwise the doctor may fail in the correlation of physical findings in the employees with conditions in the plant and the correction of conditions that prove to be harmful. Industrial hygiene properly belongs in the medical department.

SAFE PLACEMENT

Having become familiar with working environments and conditions, the doctor is able to advise in the safe placement of new workmen. In order that new workmen may be assigned to occupations for which they are suited and can safely perform, a knowledge of their physical conditions is necessary. To obtain this knowledge is the purpose of the preemployment examination. Certainly it must be sufficiently thorough to enable the doctor to advise intelligently as to placement. As this is only the beginning of the workman's plant life, the examination must also serve as a source of information to guide the doctor in his subsequent efforts in behalf of the workman's health and his continuing safe employment.

The examination should be a reasonably complete physical study, supplemented by roentgenograms of the lungs and such other procedures and tests as the doctor considers to be essential. This examination is the doctor's introduction to the workman. If he impresses him as being an able physician, honestly interested in employee health, he has gone far toward building up the employee's confidence and good will, which are so necessary to health maintenance. A doctor cannot well serve an employee who has little or no confidence in him.

PHYSICAL SUPERVISION

Important though it is, the preemployment examination must always be considered as a preliminary in the plant physician's subsequent physical

supervision of the employee. It brings out information which he needs for comparison with the findings obtained by periodical examinations.

These periodical examinations are to secure early diagnosis of preventable diseases and adjustments in occupation if necessary. They are essential to the control of occupational diseases. They should be as complete as the doctor requires for a conclusion, and they should be made often enough to give the workman health protection, but not less frequently than annually.

A workman being transferred from one department to another should receive such examinations as may be necessary to safe placement in the department to which he is being transferred.

Reëtrance examinations should be made after absence from illness or injury. They are to protect workmen against a too early return to usual work or to effect changes in occupation if indicated. These need not be more extensive than in the judgment of the physician is required to safeguard the workman and the employer.

It is only natural that the workmen consult the doctor from time to time about personal matters and, although he will not attempt to treat them, for that properly belongs in the field of private practice, he will take advantage of the opportunity to consult and advise. In order to do this, it is essential that an examination be made. This examination is such as any doctor might make for diagnosis and counsel.

HEALTH INSTRUCTION

The best of health instruction is that which follows physical examinations or accompanies consultations. This is personalized instruction and as such is very effective. Every visit of every employee to the medical department, and these frequently equal 100 per cent of the total number of the employees

monthly, makes an opportunity for health instruction.

RECORDS

These should show the results of all physical examinations and consultations and will include particularly detailed reports on injuries and illness, descriptions of physical findings, treatments, estimated periods of disability, end results, and all other information pertinent to cases or required by statute for Workmen's Compensation claims or other purposes. In short, records should be sufficiently complete to permit the making of statistical studies.

CASE FINDING

In the course of preëmployment and periodical examinations and in connection with consultations, the physician will discover conditions that require treatment. This case finding function of industrial medicine has far reaching consequences in the field of health maintenance. It is very apt to uncover and encourage treatment of a great variety of pathological conditions and diseases which, under ordinary circumstances, will not receive attention until farther advanced.

Needless to say, employees found to be suffering with correctable conditions are referred to their family physicians. This phase of industrial medicine serves as an important agency for the general profession and the public health authorities. This is particularly true with reference to tuberculosis, syphilis, the cardiorenal diseases, vascular diseases, and many others which need not be mentioned.

STUDIES OF SICKNESS

It is seen from the foregoing that the plant physician has a splendid opportunity to accumulate data relative to the instance of non-occupational sickness and injuries as well as the occupational. Although not a responsi-

bility of industry, their prevention and control is preëminently desirable. As a means toward this end, the plant physician collects and analyzes statistics concerning sickness relating to occupation, sex, age, and other facts that may involve, or be involved, in the health of the workmen.

At the moment, industry, generally speaking, has little or no knowledge of the losses which accrue to the employees because of non-occupational sickness nor have they any knowledge as to the losses which accrue to industry. Statistical studies will divulge this knowledge, will enable industry to contribute its share toward a disease prevention program, and will serve as a basis for the definition of the responsibility of the general medical profession, public health authorities, and the community, in relation to employee health.

COÖPERATION WITH THE MEDICAL PROFESSION

By this time it has become apparent that the plant physician is dependent, to a large degree, upon the local medical profession, and that the local profession is, in reality, an element in the plant medical service. It is desirable, therefore, that the industrial physician make it clear to the local profession that although he is in a sense an uninvited consultant, he is at the same time a very valuable ally. He should attend medical meetings, mingle with the local hospital groups, and take a place in local medical circles appropriate to the position which he occupies and commensurate with his opportunities for service, not only to industry but to the community itself. He must never assume the rôle of the private physician.

COÖPERATION WITH OFFICIAL AND NON-OFFICIAL AGENCIES

Industrial medicine is coming to realize more than ever before its opportunities for service in the public health field.

It is the only organized point for attack against the preventable diseases in the employed group, which is, in reality, a definite age group. Industrial medicine may serve in the public health field for this group in a manner much as has already been done in relation to infants, children, and adolescents. This opportunity becomes increasingly evident as the control programs for tuberculosis and syphilis develop.

Plant studies of non-occupational sickness are obviously supplemental to the community studies of sickness, the so-called vital statistics, and epidemiological studies in the plants, a brilliant conception of J. J. Bloomfield, have the same import with respect to the health of the employed group as epidemiological studies of the community itself.

Details as to methods for coöperation with municipal and state health departments and nonofficial agencies are not needed. All physicians are familiar with the routines. It should, however, be made clear to these departments and agencies that in industry is a valuable ally in promotion of community health.

CONCLUSIONS

By virtue of his place in industry, his responsibilities, facilities, and contacts, the industrial physician is able to contribute substantially to the health of his community, and in so doing is able to further very considerably his own health maintenance program. In addition to the now accepted procedures of environmental plant studies, preëmployment and periodic examinations, consultations, and health instructions, he sees even greater possibilities in extensions into the broad field of public health by statistical studies of non-occupational sicknesses in the employed population, epidemiological studies of those groups that show a high incidence of disease, and a well coördinated plan of coöperation with medical and public health agencies.

PATENT MEDICINES AND ADVERTISERS

THE nostrum evil flourishes in most parts of the world. The Scandinavian countries, Czechoslovakia, Switzerland, and a few others are better protected in this regard than the United States, Great Britain, France, and many South American countries.

The fight against patent medicines has been a long and sickening one in this country, and only recently have we succeeded in getting a law passed which has raised expectations for better things. It is too much to hope that the fight is over and that the victory is complete or permanent.

Reports from England indicate that the trade in quack medicines has been growing enormously, so much so that Lord Horder has been led to take up the matter in the House of Lords. He has pointed out in a masterly way the evils of the business and the inconsistency of allowing it to grow and flourish at a time when the government is making nation-wide efforts to improve the national fitness. It is stated that in England the patent medicine trade takes from the public between 125 and 150 million dollars a year, which is about the same amount as spent on hospital services. This money comes largely from that part of the public which can least afford it. Where the government spends \$500 for health for the public, the patent medicine industry pays \$5,000 to make them disease conscious. For the medicines recommended for nervous and digestive disorders alone approximately 5 million dollars will be spent in advertisements during the coming year. Lord Horder pointed out that when he proposed to take up the fight against the patent medicine evil he was warned that he would arouse against him the great advertising interests and would have to fight the proprietors of the newspapers. It was evident in England, as in this country, that the advertising interest is the chief obstacle to be overcome in any attempt to improve matters. Efforts to improve the laws regarding foods and drugs have always been met by a well organized lobby of advertisers, supported by highly paid legal lights. Practically all that he said is an old story in this country, where it is said that the national advertising expenses amount to about a billion and a half dollars a year, of which newspapers get approximately 700 million, mail advertising 400 million, magazines 210 million, and billboards 75 million, press and trade papers about the same amount, in addition to which are

the radio, premiums, special programs, street car cards, etc.¹ At least five patent medicine concerns have each paid more than a million dollars a year for newspaper advertising. In 1933, twelve corporations spent more than a million each for magazine advertising and the total cost of magazine advertising for 150 corporations was \$93,987,970 for the year 1933.¹ In England, as in this country, advertising is a specialized profession. The manufacturers of a nostrum hand their material over to a specialist who plans the campaign and places the advertisements. Lord Horder believes that the advertisements have become a greater danger even than the remedies since they play on the fears of people, and the healthy as well as the sick are swindled.

In England, as here, while some proprietary remedies are fairly good in themselves and the claims made for them fairly reasonable, not infrequently preparations are sold that do definite harm. This applies not only to medicines for internal use but also to those for external application, and especially to cosmetics. Our recent experience in this country with the Elixir of sulphanilamide is an example of what has been possible here, and seems to be possible in England now. The patent medicine interests and the advertising specialists are more quick to catch on to new ideas than the medical profession. No sooner is a discovery made and published than the advertising specialists take hold of it and exploit it. In England this is shown particularly by the change from advertisements of cancer and hernia cures to those directed against rheumatism, which is coincident with the many studies and great interest which that disease is now attracting in that country.

The radio has brought to us an entirely new problem and we have recently reviewed in these columns a book devoted to the abuses of radio advertising of patent medicines. The matter has very properly attracted considerable attention. The broadcasts reach an enormous audience. In 1935, the drug manufacturers spent \$15,986,507 on radio advertisements.² That they can afford to spend such vast sums shows the profits derived from the business.

A number of books have been written, chiefly by laymen, on the drug evil, and some by medical men. The Massachusetts Agricultural Experiment Station, *Bulletin 342*, has given one of the best expositions which have come to our attention. This *Bulletin* of 30 pages covers the subject in a masterly way and ends by giving a list of 10 articles and books which can well be studied. Other books, like *The Traffic in Health*, written by a physician, have appeared. The matter is one of the greatest interest and importance. The public health and medical professions owe it to the governmental agencies and to the public to give support to such laws as exist and to make every effort to aid in their efficient administration.

"We may be perfectly certain, as these lines are being read, that groups of shrewd men, here and there around our fair land, are busy sharpening their wits to try to find loopholes in the new Food, Drug, and Cosmetic Act that will let them continue to thimblorig, bamboozle, dupe, dope and poison innocent sufferers, and make millions out of it. Are these gentry going to reform and turn into plaster saints just because Congress has passed a law? Not unless human nature has had a total transmogrification."³

BOVINE TUBERCULOSIS IN CHILDREN

WE have commented before on the work being done on this subject at the University of Toronto under the National Research Council of Canada. Another report covering 13 years has been issued.¹

Toronto is a particularly good place in which to make such an investigation since the pasteurization of milk is compulsory and the laws have been rigidly enforced since 1915; hence we have the comparison between the children who live in Toronto and those brought in from the outside. Through private physicians and sanatoria a number of tuberculous children from the Province of Ontario have been seen.

In a series of 500 tuberculous children, in 9.6 per cent of extrapulmonary tuberculosis the bovine type was found to be the infecting organism. Bovine bacilli have been recovered from bones, joints, glands, kidneys, meninges, serous surfaces, tonsils, adenoid tissue, and skin. With the exception of primary tuberculosis of the lung it has been found that no organ or tissue of the human body is immune to infection with the bovine type of organism.

The children in whom the bovine tubercle bacillus was found have come to Toronto for treatment from Ontario, some other Provinces, and some other countries, in all of which the milk supply was not pasteurized. In every case it was found that the tuberculous children had been fed raw milk. In three instances it was possible to obtain a sample of the milk used and to study it by guinea pig inoculation, and in three cases the disease was actually traced to the responsible animal.

It is interesting to note that since 1926, when this investigation was begun, much progress has been made in Ontario in the control of bovine tuberculosis and its eradication. Among 850,000 animals tested, 12.8 per cent of those found to be reactors have been removed and pasteurization has been introduced into many municipalities, 50 having adopted compulsory pasteurization in 1938. In 75 others a large part of the market milk is pasteurized. The present report shows that the incidence of bovine tuberculosis in children has fallen from 13.5 per cent in 1935 to 9.6 per cent at present, which is attributed both to the control of cattle tuberculosis in Ontario and to the greater use of pasteurized milk. No better proof of the value of pasteurization could be given. It seems strange that any opposition still exists.

THE FEAR OF AIR RAIDS

IF there are any who do not realize how fortunate we are to be living in the United States in spite of all the many things which make us apprehensive and perhaps unhappy, even a casual perusal of the general feeling in England, for example, toward air raids will make us appreciate the advantage of life here over that abroad.

We have already called attention to the manufacture of some 45 million gas masks and the drills in their use which are carried out even down to school children. That this constant apprehension must have some decided effect on

character and health goes without saying, but there is another aspect which demands attention—in some ways a more practical one.

At the recent Portsmouth Health Congress, a conference on Air Raid Precautions was held under the Presidency of the Lord Mayor of Portsmouth.¹ The Lord Mayor, in his opening address, said it was a sad reflection that at a time when local authorities were engaged in increasing and improving the social services of the country they are forced to prepare to meet a menace from the air. The isolation and safety which Britishers have felt for hundreds of years, owing to their insular position, existed no longer and that at least the early part of the next war would be waged literally on their very door steps. In view of this, the government has placed upon the local authorities the duty of passive air defense. It was an entirely new departure for local authorities which raised many problems never thought of.

A series of set discussions by six officers of the City Council followed—the Town Clerk, the Medical Officer of Health, the Chief Constable, the City Engineer, the Engineer and Manager, Portsmouth Electricity Undertaking, and the Transport and Cleansing Superintendent, upon all of whom special duties and responsibilities would fall.

There has been issued a 76 page "Air Raid Precaution Handbook (Provisional)." In July, 1937, combined coast defense exercises were carried out by the three defense services, including a complete "blackout" of the Portsmouth naval area, and more extensive exercises took place in March, 1938.

More important to us is the public health aspect presented by Dr. A. B. Williamson, Medical Officer of Health. He said that the energies of health officers are already fully absorbed in expanding health services necessary to keep pace with the great amount of recent public health legislation, and yet a new responsibility had been placed upon them which certainly requires increased personnel and a greatly increased expenditure. Except for the wonderful invention of the Wright Brothers in America, this problem would not exist today, but it is here to stay and the Air Raid Precaution Casualty Service must be a permanent organization, as man will continue to increase the speed, range, and effectiveness of the plane as a weapon of war.

The layout of the modern health department is not unsuitable as a nucleus of a casualty service. The ordinary duties are militant, the organization built up to fight against an unseen enemy—disease germs. Sanitary inspectors, disinfecting staff, health visitors, and tuberculosis nurses may be termed advance troops attempting to destroy the enemy on the outskirts. They are now called upon to build up a casualty service for those who may become victims of another kind of enemy—airplanes. The casualty service has always played an important part in war. The precautions advised and now being taken would have a very important part in preserving the morale and building up confidence that casualties would be dealt with rapidly and efficiently. The Medical Officer of Health is the man who must be responsible for an efficient emergency service; consequently, an Air Raid Precaution Casualty Service Section should be created within the health department, and in large local authorities of strategic importance there should be a medical officer for air raid precautions with an office, the assistance of a whole time senior clerk and stenographic service.

In addition, there should be in every exposed city a large model first aid post, centrally located immediately available at the outbreak of hostilities. The plan and description of the one for Portsmouth, designed by the City Architect,

is given. Among other necessities is a "Mustard Laundry," in order to handle clothing which had come in contact with poisonous gases. This is better situated at the infectious disease hospital where laundries for infected clothing, which can be easily adapted to the new uses, are already located.

From the public health standpoint, perhaps equal in importance to the health officer is the city engineer, under whose care comes the maintenance of roads and communications, repairs and maintenance of sewers, sewage pumping stations, sewage disposal works, the protection of such buildings as schools, hospitals and institutions, shelters for the public, protection of gas, electrical, and water supplies, training of personnel, and rescue of persons from buildings damaged in a raid. Of course, all of these things require tools, plant and other equipment, including facilities for transport, special vehicles, etc. Precautions must be taken against high-explosive bombs, incendiary bombs and gas bombs. Indeed, it is impossible to enumerate here all the different responsibilities which must fall upon the engineer. In addition to the maintenance of the water supply, precautions must be taken for decontamination. Reservoirs which have been polluted during air raids must be cleansed and made fit. In Portsmouth, the City Council has already included 60,000 pounds (normally \$300,000) for 1938-1939 as a first installment for expenses of the Air Raid Precaution Program. Portsmouth is an important place and would perhaps be one of the first objects of an air raid by an enemy, but the program already under way there and the huge expenditure as the first installment will give an idea of how the people in the exposed parts of the British Isles are feeling.

As during all the years of our existence as a country, so now we should still feel thankful for the Atlantic Ocean which lies between us and the countries in which so much unrest and bitterness are evident. In spite of the prediction of what man will do with implements of war in increasing their destructiveness and range, we indulge the hope that we may never be called upon to take such precautions as England feels to be necessary, and never be under the mental strain which is so evident there and in other European countries.

AN UNUSUAL SUICIDE

CURIOUS and unusual methods of suicide are occasionally reported, but as far as we are aware the instance here recorded¹ is the only one brought about by the injection of virulent tubercle bacilli into the veins.

The subject was a medical man 29 years old who had a family history of tuberculosis and who had probably suffered himself from a pulmonary lesion. Two days after the injection, fever began and persisted until his death at the end of 3 months. Nine days after the injection a radiograph showed normal lung fields, but one taken 23 days later gave a typical picture of miliary tuberculosis, and one taken 12 days before death showed confluence of the shadows. Enlargement of the spleen was observed within a few days, but there was neither cough, dyspnea, nor sputum until shortly before death, which was due to meningitis. Most interesting were the blood findings on repeated examination. At first there was a relative mononucleosis with 53 per cent neutrophils, and then

a gradual increase of this type up to 90 per cent. Eosinophils were absent throughout the case.

Ten days after the injection no culture of tubercle bacilli could be isolated from the blood either by Loewenstein's method or by animal inoculation. These results confirm the experiments made by Nocard in 1888 and by Bang in 1891.² The report states that while it is practically certain that bacilli reached other organs in the body, clinical lesions were found only in the lungs and meninges. Another point is that this case appears to prove that under some circumstances exogenous reinfection may overcome immunity acquired from previous clinical disease. It must be remembered, however, that the dose here was overwhelming and we have always taught that immunity was to a large extent relative and can be overcome by various adverse circumstances or a combination of them.

PUBLIC HEALTH EDUCATION*

Syndicated Health Education—
The "Annual Directory of Syndicated Features" lists the following writers of health columns:

Dr. George W. Crane, Dr. A. Markowitz, John C. Kraus, Dr. Herman N. Bundesen, Dr. Lewis Haney, Dr. Morris Fishbein, Dr. I. S. Cutter, A. J. Balkins, M.D., Stanley Miller, Dr. Frank McCoy, Dorothy Ducas and Elizabeth Gordon, Dr. Iago Galdston, Artie McGovern, Jane Stafford, Dr. William Brady, Dr. James Barton, Dr. W. E. Aughinbaugh, John C. Kraus, Josephine Lowman, Dr. C. N. Chrisman, Dr. Claud N. Crisman, Dr. Logan Clendening, Royal S. Copeland, M.D.

The Directory is included with the Sept. 24, 1938, issue of *Editor and Publisher*, Times Bldg., New York, N. Y. 10 cents.

Exhibits All the Year Round—
At a session of Natl. Conference of Tuberculosis Secretaries, Raymond H. Greenman of Rochester presented "The Use of Exhibits in Mass and Group Education."

Here are selected paragraphs:

We use our exhibit—little stages, pictorial statistics, shaded maps, poster drawings—to arouse interest in a particular need or service; and as we were interested in more than one need, the number of our exhibits has increased.

We find that pictures of real persons are more effective than drawings. We cut up and mounted the figures on billboard posters which we bought from the National Association and our progressive State Committee, and we noted the reactions of our own committee members to the reading of X-ray pictures and posters illustrating approved modern methods of finding and treating early tuberculosis.

We wanted our exhibit material to be in use all the time. We were able to set up a

health teaching center in a vacant home next door to our building. Last October, this center was officially opened, intended especially for the information of professional groups not primarily for the general public. To this center have come doctors, nurses, social workers, health education teachers, in groups of from 20 to 100—more than 1,000 of them. At this center our Board and all our Committees meet—300 representative citizens. Here we show sound motion pictures and here we not only show exhibits but we submit our material to critical analysis. We analyze our points of contact and we follow out the constructive suggestions of our friendly critics. . . .

Now our exhibit service is functioning 12 months of the year instead of only at the time of an exposition or a county fair, or a convention. The sizes of our exhibits vary from 2 feet square to 15 feet by 10, the larger ones carried by a trailer. All our exhibit material is framed and in good condition, and has the specific approval of our medical advisers.

Fifteen years ago we spent \$800 for a "Healthy House" exhibit during Labor Day Week at the Rochester Exposition. This past year we spent \$500 for the maintenance of our teaching center and 10 exhibits which were carried to all parts of our county.

Next year in the new home of the Rochester Academy of Medicine an exhibit space is being provided on the first floor for a modern "Museum of Health." We are committed to assist in providing exhibit material dealing with modern methods of health preservation. These are intended to be of special interest to doctors' wives who are important people in the community.

How about Staff Conferences?—
We don't know how general are staff conferences outside the nursing groups. As training on the job they ought to serve more groups than nurses only. As a builder of a better working staff they should be of general service.

Our Nurse, City of New York Dept. of Health (June, 1938) answers "Why have staff conferences?" from the viewpoint of nurses:

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

This question was recently put before a group of newly promoted Health Department supervisory nurses. From their own experiences they contributed many and varied reasons. Among them were: to improve services; to discuss a common problem; to present new material; to explain new procedures; to analyze a case history; to encourage staff participation; to raise morale; to plan for the future; to interpret vital statistics; to become better acquainted with each other; to learn the needs of the staff; and to take time out to think what one is doing.

Then here are some of the questions which face those who undertake staff conferences:

How to prepare material for staff conference? how to organize the physical set-up for a staff conference? how to lead the meetings? how to present material? how to summarize? how to meet individual needs? how to get group participation in staff conference? what can be done with a person who dominates? how to bring out silent members? what to do if the group becomes restless and how to stimulate interest?

Exhibits and Museums—The interest of the American Assn. for Health and Physical Education is explained by Agnes Wayman in "Educational Exhibits and a Permanent Historical Museum," in *Journal of Health and Physical Education*, 311 Maynard St., Ann Arbor, Mich. May, 1938. 35 cents.

On the one hand our national organization is encouraging educational exhibits in connection with state, district, and national conventions, and on the other hand it is locating material which might have significance historically in relation to the development not only of our organization but of value in connection with the evaluation of our whole field of education. It is doing this with the hope that eventually we shall have somewhere a permanent historical museum for health and physical education. Before expanding that idea, it might be well to discuss further the first type of educational exhibit mentioned.

With the increased emphasis upon visual education material, some of us realized that as an organization we were missing a big opportunity educationally as well as promotionally, so about 1934 we began to expand this idea of exhibits at conventions for various reasons:

1. As teaching aids they are very suggestive.
2. They help to create interest in the field.
3. They may present material of value historically, physiologically, etc.

4. They serve as propaganda in the promotion of the various phases of our field among (a) our own profession, (b) schoolmen and the more academic side of education, (c) the layman (business and professional men and women, the clergy, clubs, etc.), and thus help to create an interest and a better understanding of our aims and objectives. . . .

It is to be hoped not only that valuable material may be developed which can later be used as museum material but that through these exhibits a greater interest will be developed in actually working out projects for such use. There is, in addition, no doubt that much of value educationally is being destroyed or lost first because we fail to realize its historical significance and secondly because of lack of space. A permanent museum would make it possible to preserve such material for posterity. . . .

Mimeography Need Not Look Dull—It's partly the choice of paper; partly the making of stencils, the use of special tools offered by the manufacturers, and the running of the stencils. But it is also the use of layout devices in the arrangement of material on the page, spacing, titling, capitalization. In other words, good mimeographing calls for attention to detail, understanding the job, giving time and skill in making the most of each job. *If you don't know all of the answers please ask questions and this department will try to supply the answers.*

Remember that there can be little excuse for sloppy, dull looking, hard to read mimeograph work.

MUCH WANTED

We did not have an answer for this letter. What would you write in reply? It is a fairly common request which comes from different parts of the country. Incidentally, it might have helped if the date of the fair had been mentioned. The date helps when one is trying to answer most letters about materials for a specific use.

I am interested in putting on an exhibit at our county fair and I am interested particularly in electrical exhibits, etc., that will teach a lesson in public health, and at the same time attract attention. Something mechanical—or electrical novelty.

Please advise me where I can obtain such material, or rent same, giving prices, etc.

REPORTING

"Annual Report" of Hygienic Institute, La Salle, Ill., helps the eye of the reader of "Comment on Activities of the Institute." There are no sub-headings, but each activity or administrative unit mentioned is brought out in black face type.

COMMENT ON HEALTH CONDITIONS

Analyzing the vital records for the year 1937, there is found some improvement over the previous year, in fact, the deaths are fewer than any year since 1933. During the year 1937 there were 270 official deaths* in the Tri-Cities, which gives an official death rate of 10.2 (per 1,000 population). However, when the figures are adjusted to include residents only it is found that there were actually only 252 deaths to citizens of our community. This gives us a true death rate of only 9.5. This rate compares very favorably with the rate for the state of Illinois, as a whole, which was 11.1 for the same year. In other words, if the state rate had applied in this community for the year 1937 we would have had 42 more deaths. If a human life is valued at \$10,000, this represents a saving of \$420,000. By way of contrast the health department spent during the year \$26,952, and claims some credit for the above saving.

However, many other factors enter into the saving of human life, which are beyond the control of health departments. For instance in 1936 there were 16 deaths from heat stroke alone and not a single one in 1937, and from all violent and accidental causes there were in 1937 only 17 deaths against 50 for 1936. The year just closed showed increases in deaths from heart disease, apoplexy and tuberculosis, but fewer from cancer, external causes, pneumonia, nephritis and diabetes. For comparison and details of life loss see tables Nos. 25, 26 and 34.

The infant death rate for the year showed a decided improvement. There were 13 deaths recorded against 17 for the year before. This gives an official rate for the year of 29.5 (per 1,000 live births) against 40.7 for the year before. When the figures are corrected for residence it is found that there were only 10 infant deaths (corrected births also less), which gives a true infant death rate of 30.7. This compares very favorably with the state rate of 43.0 for the same year.

Two maternal deaths occurred during the year, which gives an official rate of 4.4 per 1,000 births. Unfortunately these deaths occurred to citizens of our own community, so that the true maternal death rate for the year becomes 6.1. For 1936 there was not a single maternal death in the entire community, and therefore the rate was 0.0. La Salle and Oglesby has not had a maternal death for two years. The state for the same year had a rate 3.7, which is the best in its history. If we averaged our rate for the two years, in an attempt to smooth out the great fluctuation that can occur in small populations, the rate becomes 3.1.

The number of tuberculosis deaths increased from 4 in 1936 to 8 in 1937, thereby doubling the official death rate from 15.1 to 30.2 (per 100,000 population). However, some of our deaths occur in the county sanatorium, and when these are

*All deaths occurring in Tri-Cities without respect to residence

From Hygiene Institute Report

"Annual Report" of New Haven, Conn., Dept. of Health is lightened by two picture diagrams. If many of the capital letters had been changed to lower case, quicker reading would

follow. The 2 page report on "Public Health Instruction" includes the statement that

A total of 184 news articles aggregating 2,668 inches of space appeared in the two newspapers of New Haven directly concerning the department and most of them prepared by the department. In addition, considerable other health promotion material was printed covering the work of other health agencies.

"Annual Report" of Massachusetts Society for Social Hygiene, 1937-1938, gives 20 mimeographed pages to addresses at the annual meeting, and a page to the business session. Such a report would be given added interest by having more than 3 headings in 20 pages. The reader would be helped by the inclusion of a "contents" page, especially if it took the form of a concise description of what followed.

The "Health" section of "Annual Report" of Council of Social Agencies, Los Angeles, Calif., is a reminder of the grouping of health agencies as a section of a general council in many cities. In not a few of these cities wise leadership has resulted in more and better health education.

"Milestones along New Haven's Highway of Health" reproduce a series of 8 murals offered by the city Dept. of Health to the local Tercentenary Exposition. In *Health*, New Haven Dept. of Health, May, 1938. Striking portrayal of problems and practices from then to now.

"New, Reestablished, and Reorganized Services of the Dept. of Health: 1935-1938." State Dept. of Health, Harrisburg, Pa.

"Health Week Report" number of *National Negro Health News*, U. S. Public Health Service, Washington, D. C. July-September, 1938. Free.

"A Quarter Century of Nursing Service. Annual report of Visiting Nurse Assn., Stamford, Conn. "Twenty-Five Years Ago" is the record of a day's

service by the one nurse first engaged, with a full page picture of the first nurse astride her bicycle. This record is balanced by "A Day in the District—1937."

"Report Mimeographed by Marian Galizanske" appears on the page after the title page of "Annual Report" of Dept. of Health, Racine, Wis. Mimeographed on one side of the sheet, 45 pages, an index, no mention of health education, 2 simply done picture diagrams, a "Forward" section (lost in the back part of the volume), and a pleasing printed cover page.

To get a picture of the educational-publicity activities of a large city health agency—see "Public Relations Department" in the annual report issue of *Quarterly Review*, New York City Cancer Committee, 130 E. 66th St.

MOTION PICTURES

"Selected Motion Pictures." Catalogue of 16mm silent and sound pictures, free and rental. Includes a few health pictures, and many other educational and diversion pictures for use in clinic waiting rooms, sanatoria, etc. Motion Picture Bureau, Y.M.C.A., 347 Madison Ave., New York, N. Y., or 19 S. La Salle St., Chicago, Ill.

"Visual Review—1938," by M. M. Witham, is an annual issued especially for school people. Of special value to any health worker who wishes to collaborate in visual education in the class room or the general assembly. Includes chapters on the high school newsreel, the use of filmstrips, and the miniature camera. Society for Visual Education, 327 S. La Salle St., Chicago, Ill. *Free*.

New pictures are announced by Health and Cleanliness Council, 5, Tavistock Square, London, W.C.1, England.

The old favorite "Giro the Germ" is to be seen in new adventures in the Council's new cartoon film "Giro Fast and Loose" which is to be issued in the early autumn. Two other new films are also in preparation—

one deals with the homes of mankind from the Garden of Eden to Nisbet House, Hackney, with its up-to-date electric equipment; the other is intended for housewives.

Offered by state and local tuberculosis associations (produced by Natl. Tuberculosis Assn.):

Rex Ingram, who played the part of "De Lawd" in "Green Pastures," plays a leading rôle in "Let My People Live." The picture will run 20 minutes. With an all-Negro cast, it dramatizes facts of tuberculosis as it affects the colored race. "Let My People Live" was filmed entirely at Tuskegee Institute, Alabama, and among its features is the Tuskegee choir of 100 voices, under the direction of William L. Dawson. The Federal Theater Project granted Ingram leave of absence from the WPA stage production, "Haiti" to make "Let My People Live." Other persons in the cast include Peggy Howard and Erastine Coles.

"Diagnostic Procedures in Tuberculosis" is the title of a new 15 minute film prepared for medical societies, public health groups, medical students and nurses. The four eminent specialists who take part in the film are Dr. Kendall Emerson, Managing Director of the National Tuberculosis Association, Dr. Ralph S. Muckenfuss, Director of the Bureau of Laboratories, New York City Department of Health, Dr. Esmond R. Long, Director of the Henry Phipps Institute and Dr. Edgar Mayer, Assistant Professor of Medicine at Cornell Medical School and formerly on the staff of Trudeau Sanatorium.

RADIO

"The Health Hunters," New York State Dept. broadcast over Station WGY, has been moved from 5:00 p.m., Saturdays, to 11 a.m.

If you have use for a list of broadcast stations, ask Federal Communications Commission, Washington, D. C., for a free copy of "List of Radio Broadcast Stations, By State and City."

"Let's Take The Air: A Manual on Radio Production," by John E. Kieffer (with Philadelphia Health Council and Tuberculosis Committee), Pennsylvania Tuberculosis Society, 311 S. Juniper St., Philadelphia, Pa. 25 cents. This will supplement the *Scholastic Magazine*.

BOOKS AND REPORTS

Occupational Diseases in Ohio: Annual Report for 1937—By *Kenneth D. Smith, M.D., and John B. Kistler, M.D.* Columbus, Ohio: Ohio Department of Health, 1938. 52 pp., mimeographed.

Following the general style of the brief annual reports published by the department in previous years, the current report adds 31 tables to the customary summarizing table of Compensable Occupational Diseases, which now covers 10 years (1928–1937 inclusive). A copy of the law covering Compensable Occupational Diseases in Ohio includes the last one to be added—silicosis—which extends the list to 22 named diseases or injuries.

From the date of the first report to the department of an occupational disease, made May 15, 1913, to the end of the year 1937, 22,027 reports were received. About nine-tenths of those reported have been on the compensable list since compensation for this class of diseases began in 1921. It should not be inferred, however, that the compensation list is nine-tenths perfect since physicians are more prone to report afflictions which are compensable.

During 1937, 1,693 reports were received of which 1,390 (82.1 per cent) were males and 299 (17.4 per cent), females—the sex not being learned for 4. The reports were made by 753 physicians, or 8.2 per cent of the approximately 9,200 physicians in the state. The workers were employed by 926 different employers.

As in past years, infection and inflammation of the skin (dermatitis), consequent upon exposures chiefly to irritants, made up about two-thirds (66.1 per cent) of the total cases, and

68.5 per cent of the compensable cases. Of these, 826 (80.4 per cent) were males and 207 (19.3 per cent) were females.

Constitutional poisonings comprised 218 cases of which 195 were lead poisonings.

Wrist-strain (tenosynovitis) affected 155, and "housemaid's knee" (prepatellar bursitis), 26. Of the latter, only 2 were females, however. Ulcers of the nose and skin, due to inhaling chromium compounds, made up 68 cases—11 less than the preceding year.

Silicosis, the last disease to be added to the Compensation Schedule (92nd General Assembly, 1937), was responsible for 40 reported cases, 19 of which were reported before the Act became effective on July 31, 1937. Silicosis cases are only entitled to a maximum of \$3,000, or less than one-half of the \$6,500 permitted for other types of occupational diseases and injuries.

The customary annual inquiry of the 21 tuberculosis sanatoria in the state was not made for the year 1937, but such inquiry has yielded only a comparatively few cases in past years, some of the larger sanatoria reporting no occurrence of silicosis cases. From this it may be assumed that few of these cases gravitate to sanatoria, or are really infected with tuberculosis.

Of the 107 non-compensable reports, 89 were males and 18 females. This group incurred all manner of physical injuries such as heat, cold, friction, pressure, repetitive motions, strains, etc., but included numerous irritants, poisons, and infections not on the Compensation Schedule.

The summarizing tables will be of

particular interest to those concerned with the various afflictions reported. In general, a gradual increase has been noted in the decade, 1928-1937. The report does not go into the matter of premium costs and disbursements, nor does it cover the number of fatal cases—these being matters within the jurisdiction of the Industrial Commission, which publishes monthly and annual summaries separately.

EMERY R. HAYHURST

Osler's Principles and Practice of Medicine—By *Sir William Osler, M.D., (13th ed.)* Revision by *Henry A. Christian, M.D., LL.D.* New York: Appleton-Century, 1938. 1424 pp. Price, \$9.00.

Only an intrepid author would undertake to reëdit the single volume edition of Osler's classic text. This Thirteenth Edition is the work of Henry A. Christian, M.D., Hersey Professor of the Theory and Practice of Physic at Harvard, who succeeds the late Thomas McCrae, M.D., as reviser. Dr. Christian has prepared the revision without the assistance of other experts. In this respect the edition resembles the first, of 1892, which was Osler's own; yet a volume which has had such a profound effect on the practice of medicine amply deserves periodic revision. Readers of the present generation may not remember that it was an early edition of this work which, when called to the attention of Mr. Rockefeller, resulted in very liberal gifts for the promotion of medical science, including the establishment of the Rockefeller Institute for Medical Research.

It is illuminating to compare this 1938 text with the Eighth Edition published in 1916, which was the last revision in which Sir William participated. Although the number of pages has been increased during this 22 year interval by only 16 per cent, the topics have become proportionately more

numerous and they reflect many of the changes in medical knowledge. Topically the volume carries most of the subjects included in the larger systems of medicine.

It is because of this convenient accessibility that the volume is important as a quick reference text readily available to public health workers. On the whole this edition is to be commended on the inclusion of statements consistent with accepted epidemiologic data, but it would be desirable if the statements on incubation time, duration of infection, and recommended periods of isolation were made consistent with the consensus of experts in this field as expressed in the A.P.H.A. report on the *Control of Communicable Diseases*. However, the present edition is much improved in this respect over earlier ones.

The critical reader will recognize modern concepts of the epidemiology of tuberculosis, syphilis, yellow fever, and the diseases of the rickettsia group. He will have to seek the documentation of the evidence elsewhere, and each specialist will doubtless discover areas in which his own opinion differs from the text. He may even wonder whether the time has passed when any person can be expected to take responsibility for all the contents of such a comprehensive volume, much of which of necessity must be other than first-hand knowledge.

Yet the impartial reader will be satisfied that the revision has been the work of as able an author as Dr. Christian and will rejoice that the oncoming generations of medical students may have access to so worthy an edition of William Osler's masterpiece.

REGINALD M. ATWATER

Vitamin B₁ (Thiamin) and Its Use in Medicine—By *Robert R. Williams, Sc.D., and Tom D. Spies, M.D.* New York: Macmillan, 1938. 411 pp. Price, \$5.00.

Vitamins were discovered only about a quarter of a century ago, although clues to the existence of these accessory food factors had been developed by scientists at the beginning of the present century. So rapid has been the progress in vitamin research, however, that now we have an entire book of some 400 pages devoted to only one of the dozen or more vitamins now recognized, catalogued, and synthesized.

The book, one of the medical monograph series edited by Dr. George R. Minot, is an excellent one in every respect. Not only does it give the complete story of thiamin, or vitamin B₁, in relation to food deficiency states and their clinical treatment, but it offers valuable material on the history, the chemical nature, and the physiological applications of this important substance. The book is written in a lucid style by leading authorities, and it is well printed, with a good index.

This treatise is a valuable contribution to the scientific literature on human nutrition. It should be indispensable to all persons who are concerned with the diet of man, a subject which continues to merit serious concern.

JAMES A. TOBEY

Technics for the Bacteriological Examination of Drinking Glasses—
Published in "Health Officers News Digest" by The Public Health Committee of the Cup and Container Institute, 30 Rockefeller Plaza, New York, N. Y., 1938.

This fine collection of laboratory procedures clearly indicates that we have passed far beyond the pioneering stage in the bacteriological examination of eating and drinking utensils. The fact that no two of the technics used in 15 different cities are identical might seem at first thought a fatal objection to the whole procedure. This is actually about as far from the truth as it could possibly be. As a matter of fact, in the

sanitation of eating and drinking lishments, the rôle of the labora a comparatively simple and minor one. By any of these procedures clear differentiation can be made between cleanliness and filth. Therefore they are all good methods. The sole possible objection lies in the fact that their results are not comparable. The Sub-Committee of the American Public Health Association on Standard Methods for the Examination of Dishwashing Devices has not claimed that its proposed technic is the best possible method. What can be claimed for it is that it is actually in use. The laboratory technicians and the sanitary inspectors working with Cumming in Washington, D. C., through information gained by this method have made their city a safe place in which to eat and drink—soda water.

The proposed technic permits not more than 500 organisms per utensil surface area examined. Is this too liberal? Purveyors of food and drink in Washington who have paid fines and lost their licenses do not think so. In practice this method has produced the desired results. It is a good method, however, chiefly because it has been and is being used.

We know now that the methods which have been in common use for the bacteriological examination of milk during several years past are comparatively crude. Even so, their application has brought about the production of milk far cleaner than that commonly purveyed prior to the widespread use of the plate count.

The eating and drinking utensil examination is a parallel case. It is time to stop calling attention to minor differences in technic. Let a uniform method be adopted, one proved in practice to be a *good* method. Then let us have reported the results of its application. What was the average count per beer parlor at the beginning of this

year, and what is it now? How do your sanitary inspectors operate and coöperate to give the health officer the information which leads to successful prosecution of malefactors. We know all we need to know about the laboratory technic—we want to know more about the field and the court technic.

Fundamentally (and within natural limits): the most useful technic is the most used technic.

Let us therefore adopt one good procedure as a comparable method, then we can all know what we mean when we say we permit not more than 500 organisms per utensil surface area examined.

The most useful is that which is the most used—*ceteris paribus*.

A. P. HITCHENS

Macleod's Physiology in Modern Medicine—*Edited by Philip Bard, with the collaboration of Henry C. Bazett, George R. Cowgill, Harry Eagle, Chalmers L. Gemmill, Magnus I. Gregersen, Roy C. Hoskins, J. M. D. Olmsted and Carl F. Schmidt. (8th ed.) St. Louis: Mosby, 1938. 1051 pp. Price, \$8.50.*

After defining physiology as "an application of the known laws and facts of physics and chemistry to explain the functions of living matter," Professor Macleod in the first edition of his book *Physiology and Biochemistry in Modern Medicine* argued for the wider use of this science in clinical medicine. By recourse to its methodology and factual material in the study and interpretation of disease, he reasoned, diagnosis would become a science as well as an art. In putting physiology forward as an applied science, he laid out his book accordingly to include only those topics with a practical bearing. Later editions, shorn of the biochemical title and of much biochemical material which had by that time asserted its own place in medicine, reached out into the entire physiological domain regardless of any

immediate practical considerations. If the form thus took on a broader gauge, it did not violate the original spirit of interest in applicability.

The latest edition of *Macleod's Physiology in Modern Medicine*, the first since Professor Macleod's death, is a collaborative work of nine physiologists. Continuing the book's trend, they have carried further its topical expansion. This is a sound design, for usually what may seem at the moment to be a matter of purely academic interest is ultimately found to have its practical turn. This new edition is, therefore, a worthy successor. To designate outstanding features in a book that is of such uniformly high caliber would be a factitious gesture. It is, however, a gratifying commentary on progress in physiology that the section on the neuromuscular system has come to occupy 20 per cent of the space in the present edition.

With the aim at present toward early diagnosis of disease, an aim that often oversteps the range of sensitivity of the usual clinical technic, the desideratum for precise procedures is constantly bringing biochemical and physiological methods into use. To those desiring to keep abreast of developments in physiology, it should be said that this book bears the stamp of authority. It is likewise appropriately designed as a textbook for medical students.

H. D. KRUSE

Cause and Prevention of Disease—*By William Harvey Perkins, M.D. Philadelphia: Lea & Febiger, 1938. 713 pp. Price, \$7.50.*

This book most certainly presents a novel viewpoint of preventive medicine. It appears to be more of a textbook of philosophy than of medicine. It is an original concept that the body of man is a "falsely isolated interference pattern" and just what that means is not clear to the reviewer.

The entire work is based on Six Categories of the Cause of Disease. No one can object to the classification since it includes all known causes of disease. The categories are: I—Inherited Factors; II—Defects of Nutritive Elements; III—Exogenous Chemical Agents; IV—Physical Forces and Energies; V—Vital Activity of Invading Organisms; and VI—Psychobiologic and Bio-social Influences. Under these various categories there is an immense amount of information packed in a relatively small volume.

About 70 pages are devoted to food and nutrition, 175 to poisons, 85 to mechanical forces and energies, 200 to invading organisms, and 65 to psychobiologic factors. There is an excellent chapter on sex hygiene. Less than a page each is devoted to pneumonia, syphilis, and cancer, all of which are important problems. More space is given to brass founder's ague than to syphilis, more space given to carbon disulphide poisoning than to pneumonia, and three times as much space given to carbon monoxide poisoning as is given to cancer. However, the book is not intended as a textbook on public health administration and it is probably true that the preventive aspects of syphilis, pneumonia, and cancer can be summed up in a few words. Brevity is often an asset in a textbook.

This book would be a difficult one for most students to cover in the time usually allotted for courses in preventive medicine, even if they could understand it. Many of the definitions are not clear. For example, (page 21) "Health is a state of relative equilibrium of body form and function which results from its (sic) successful dynamic adjustment to forces tending to disturb it," and (page 489) Immunity is defined "as a state of resistance and antagonism toward invading organisms due to particular qualities aroused in the tissues of the host in response to particular qualities

possessed by the pathogen." The book would be more readable and more easily understood if fewer and simpler words were used. As it is, much of it is polysyllabic to an extreme.

There are a number of errors which should be corrected in future editions. On page 420, we are told, "The thermal death time of a species of bacteria is the time required to kill the organism at a given temperature or range of temperature. . . . For example, milk is readily sterilized by pasteurization at 63° C. (145° F.) for thirty minutes, its thermal death time at this temperature." This language makes milk a species of bacteria. Sterilization and pasteurization are not synonymous, and most pasteurized milk is not sterile. Again, (page 498) "In rural areas this is most frequently the homestead with its stream, spring, well, or cistern. All of these sources can be readily contaminated the most common coming from circumstances which permit the entrance of human and animal excreta." To what does "the most common" refer? The success of botulinus antitoxin in combating botulism after it has developed is open to question. No mention is made of the use of magnesium oxide for treatment of drinking water containing fluorine.

As a catalog of all the possible ills to which the human being is subject, mentally, physically, and morally, the book is unique. We do not believe the relative amount of space given to different subjects is wise. The author correctly says, "In no other field of preventive practice is there more hope of success than in the science of nutrition"; yet only some 70 pages are given to it against 175 to poisons.

The author has compressed an enormous amount of information into this volume and deserves credit for a refreshing viewpoint in writing what is probably the most difficult book there is to write—a textbook of preventive medicine.

The printing and make-up are excellent, though some misspellings have escaped the proof reader. The index is good.

F. L. ROBERTS

A Textbook of General Bacteriology—By Edwin O. Jordan. Revised by William Burrows. (12th ed.) Philadelphia: Saunders, 1938. 808 pp. Price, \$6.00.

The 11th edition of this well known text appeared in 1935. Since then we have had to mourn the death of the author, and the revision for the 12th edition, which is just off the press, has been made by the Assistant Professor of Bacteriology at the University of Chicago.

Several sections have been entirely rewritten. Owing to the great interest which attaches to the virus diseases and the amount of study given to them, the most extensive revision has been made in the chapter concerning them. Another disease of great importance and on which much work has been done since the last edition, is poliomyelitis, so the section on this disease has been entirely rewritten. The chapter on influenza has been moved into the virus disease section and extended to include the recent work on the identification of the virus. The many new discoveries in regard to yellow fever have required that this subject be considerably amplified. All through there are evidences of careful revision in order to bring the book up to date.

There are, however, still some parts which cannot be regarded as up to the minute. An enormous amount of work has been done on the so-called coliaerogenes group. There is no standard nomenclature for the various related organisms included in this group. The term "coliform" has been proposed by Breed and Norton and is being used in England to a considerable extent. The text still clings to, and quotes at length, the 6th edition of the Report

on Standard Methods of the A. P. H. A., 1925. The Standard Methods of the A. P. H. A. is the only authoritative publication on the subject, but the edition quoted is 13 years old and cannot be regarded as entirely satisfactory in light of the knowledge gained in the meantime. We do not understand why the 8th edition published in 1936 was not quoted. This whole subject is of especial significance in regard to the examination of water and of milk. The text does not even mention the phosphatase test to determine the efficiency of pasteurization.

The volume contains practically the same number of pages of text as the 11th edition. The Index is longer but the total size of the book is nearly 20 pages less, since the Index of Authors given in the 11th edition has been omitted.

The printing and make-up of the book are excellent. The first edition appeared exactly 30 years ago, and since that time it has been a standard. All bacteriologists and teachers have looked forward to the successive editions and have not been disappointed. We welcome the present revision which enables the book to keep the place of usefulness it has held for so long, and keeps before us the name of an honored teacher.

MAZYCK P. RAVENEL

Pasteur: Knight of the Laboratory—By Francis E. Benz. New York: Dodd, Mead, 1938. 232 pp. Price, \$2.00.

This life of Pasteur was written for older boys and girls, and by an author who knew how to do it well. Pasteur's life was dramatic from the time he left by bus from his home village for Paris through all the years of maturity during which he achieved many things for the benefit of mankind. Pasteur was versatile. He started with chemistry and wound up in biology. Occasionally he got into knock-down fights

with real and pseudoscientists. He had a simple Christian faith and was devoted to his family. Tragedy struck him several times. He was finally honored by governments in many countries. All these happenings were amply recorded at the time in documents and letters to give joy and enthusiasm to later authors fired by a zeal to keep Pasteur's light burning brightly in succeeding generations. This is the kind of book which should be in the library of every school and every public health worker who needs well written source material to pass on to the public to make his own local work better understood and kept on the upgrade. W. W. PETER

The Laboratory Diagnosis of Syphilis—By *Harry Eagle, M.D.* St. Louis: Mosby, 1937. 440 pp. Price, \$5.00.

No other tests performed in public health and clinical laboratories are subject to so many ramifications—including technics with their inherent difficulties, opinions of laboratory workers, personal idiosyncrasies—as those used in attempting to aid physicians in the diagnosis of syphilis. Experts will disagree on every phase of the laboratory work, methods as well as interpretation of results. The author has rendered a real service in presenting an extensive discussion of the more important laboratory tests and the theoretical bases for them. Although the book can be read intelligently only by well trained and experienced laboratory workers, it should be placed in the hands of all those engaged in serological laboratory diagnosis. If no other purpose is served than to confuse the inexperienced or inadequately trained laboratory technician, of whom we suspect there are altogether too many, to the point where tests for diagnosis of syphilis will be discontinued, the author's effort will not have been entirely in vain.

It is not possible even to mention many of the very excellent discussions, in our opinion the best now available. Much time and care on the author's part are evident in all of them. The Wassermann reaction is thoroughly discussed both from a theoretical and a practical standpoint, including a summary of commonly encountered difficulties. Three modified Wassermann procedures are described. One is the author's own technic, the second is the Kolmer method, and the third a procedure using human cells. The value of including this last is doubtful because of the admitted difficulties involved but is justified by the author on the basis of possible non-availability of sheep cells.

The mechanism of the various flocculation tests and the factors influencing the results are discussed in considerable detail in an effective and clear manner from the standpoint of colloidal chemistry. The basic reaction in both the flocculation and Wassermann tests is regarded as identical. The "reagin" of syphilitic serum is regarded as a "specifically reactive globulin which is deposited on the surface of the antigen particles." This film acts as a protein sensitizing agent in the flocculation test. The summary of requirements for a satisfactory flocculation test should be read by those interested in choosing one of the various methods in vogue. Seven flocculation technics are described: Eagle, Hinton, Kahn, Kline, Meinicke, Müller-Bollengs and Sach-Georgi-Witelesky. The author apparently prefers those tests which depend on "clarification" (Eagle, Hinton) as against those dependent on "opacification" (Kahn). It must not be inferred, however, that other than a broad view has been taken. The chapter dealing with comparison of serologic technics, including a discussion of the relative methods of Wassermann and flocculation tests is particularly to be

commended. The author recognizes that there is something more to be considered in choosing a test than sensitivity and reliability, *i.e.*, "technical simplicity" and "reproducibility" under the conditions of work.

The discussions of the interpretation of the results of serologic tests are recommended for consideration of laboratory workers and of those for whom the tests are made, physicians.

The book leaves the reader with respect for the author's opinions and admiration for his ability in accomplishing so well such a difficult task.

JOHN F. NORTON

Dynamic Causes of Juvenile Crime—By *Nathaniel D. M. Hirsch, Ph.D.* Cambridge, Mass.: *Sci-Art Publishers*, 1937. 245 pp. Price, \$3.25, plus 15¢ postage.

This is a challenging book. It is based upon a wide experience as a clinical psychologist and a detailed study of 1,000 case histories of delinquent children, a number of typical individual case reports being summarized. The author classifies the causes of juvenile crime under 4 main headings, 2 of which are not usually considered in similar studies. To heredity and environment Dr. Hirsch has added "accidental causation" which he has "defined negatively as that causation which has social effect but is beyond environmental control; is independent of hereditary functioning and also relatively unrelated to the social causation inaugurated by genius." "Genius," he feels, while "an elusive and only mediate cause of juvenile delinquency," has an enormous influence upon "the spirit of the nation, community, age." "When there is a dearth of geniuses, or when the dice of the times are too heavily loaded against them, second and third rate 'leaders' occupy positions of first rate responsibility. The spirit of the nation and of

the age reflects these leaders and, not merely bread and circuses, but kidnappings and mutilations become the demand and ideals of the day."

According to the author, juvenile crime is a symptom complex resulting from pluralistic causation and forming a *gestalt* which may be considered under one or more of the following: (1) Defective intelligence, (2) General instability, (3) Hyper-suggestibility, (4) General immaturity, (5) Home conditions, and (6) Neighborhood. The author challenges the generally accepted view that broken homes and a poor milieu are highly significant factors in the production of juvenile delinquency. As contributing factors he mentions: (1) Psychopathic Personality, (2) Constitutional Inferiority, (3) Adolescent Paranoid types, (4) Endocrine Disturbances, (5) Emotional Conflicts, and (6) Inferiority Complexes. The stand is taken that delinquency is grounded in many causes and that no one cause is usually responsible for juvenile crime. These causes are well analyzed and discussed and data tabulated to substantiate the conclusions reached.

In the Summary and Suggestions Dr. Hirsch gives us a clear picture of the results of his study. His philosophic deductions are thoroughly pessimistic and hold very little hope for the immediate future. Only through the miracle of spontaneous generation of a galaxy of men and women of genius can we be saved from the corrosion of crime!

We are applying only ineffective palliatives today. "No solution of any of the myriad of major problems is possible without the sudden appearance of men of Genius—men with kingly chromosomes, of philosophical mold, of far-reaching vision. Without such a miracle there is no salvation for the Western World of 1936. But perhaps the gods are again interested in our

planet and will create a bevy of philosophical, kingly geniuses by the sowing of dragons' teeth."

L'homme propose, et Dieu dispose!
RICHARD A. BOLT

Social Agency Boards and How to Make Them Effective — *By Clarence King. New York: Harper, 1938. 102 pp. Price, \$1.25.*

The thesis of this small volume is that social work in any one community cannot long remain at a level above that wanted by a majority of the citizens, and that a good board is the best medium yet found for interpreting social work to the public as well as the community's wishes to the agency staff.

Pointing out the advantages and disadvantages of boards, the author gives practical and concrete advice as to how to make good ones, taking up the problem from the viewpoint of both the private and the public agency. He discusses who should be members, how much authority they should exercise, and what the relationship of the board to the community and to the executive of the agency should be.

The book should be profitable reading for all who are or plan to be board members, as well as to the members of staffs of agencies that have boards or are considering having them. It should certainly be read by anyone who is considering taking a position that will include dealing with an agency board.

CATHERINE GROVES PEELE

Fearfully and Wonderfully Made: The Human Organism in the Light of Modern Science—*By Renée von Eulenburg-Wiener. New York: Macmillan, 1938. 472 pp. Price, \$3.50.*

This book contains 32 chapters, an appendix, bibliography, index, and covers an astonishing variety of topics. These include the physico-chemical

properties of the cell, cell division, fertilization of the ovum, chromasomes, genes, embryology. Some of the other major topics are the structure, function, and mechanisms of the various tissues and organs; the digestion and absorption of carbohydrates, fats, proteins, and mineral salts; the intermediary metabolism of the various nutrients, and the end products of their metabolism including energy; chemical asymmetry; ductless glands and hormones; vitamins.

The final chapter is, "The Human Organism as a Whole," and the diversity of its content may be indicated by a few of the subjects discussed. These include: "The genes as electromagnetic fields. Death as an organismic phenomenon. Memory as a function of living substance. Bio-electric phenomena. The new physics and the biologists' interpretation of life."

The wide variety of material throughout the book is indicated by a few selected minor topics. These are: "Emulsification; physical forces of surfaces, surface tension, and division of liquids into drops. Physico-chemical structure of water. Physico-chemical laws of gas exchange: diffusion, solution, partial pressure, and density. Electron, proton, neutron and positron. The rôle of electrolytes in physiological functions. Methods of expressing hydrogen-ion concentrations."

Needless to say most of the content will sound more familiar to the lay reader than the topics listed above. For the most part it is a straightforward account of established facts, with definite acknowledgment of the limitations of our present knowledge. The citations to the literature end with the year 1936. As suggested by the title, and appropriately in this type of book, there is also considerable of hypothesis, and of speculation. These are necessary if the frontiers of our present knowledge are to be expanded.

Much of the content of this book is outside of the reviewer's training and experience, but he is convinced that the author is a serious and conscientious student, and that with minor exceptions the factual content is authentic. There are some lapses however in the portions of the book which the reviewer feels able to read critically; so it is assumed that they occur in the other portions also. For that reason the reviewer believes that when reading this book any student who is attempting to become a specialist in any phase of biological science should be on guard. For the lay reader who wishes to satisfy his curiosity as to the structure and mechanisms of the body these errors are probably of no consequence.

The book is written in textbook style, with no effort at embellishment, and no attempt to introduce so-called human interest features. The book was not written for entertainment, but to supply a broad outline of the structures of the body, and of the mechanisms by which its functions are performed. It is sketchy, of necessity, but it was written for those who want a composite picture of all phases of human biology, showing the important facts in their relations to each other.

Some scientific equipment is necessary to read the book with any understanding, and the minimum prerequisites would seem to be zoölogy and organic chemistry. It is impossible to make easy the understanding of a complicated and difficult subject. As indicated previously a few errors have crept into the text, examples of which are listed below.

Page 43, "if milk sugar is ingested . . . it is practically left intact." This is not in accord with experimental evidence. Page 58, "ammonium" is used as a noun. Current usage would make it read ammonium hydroxide. Page 133, "obviously the representatives of life do not follow the second law

of thermo-dynamics." This would deny that the earth receives energy from the sun. Page 147, "The exact composition of the fat is a characteristic for each species." This statement is usually true, but it does not apply to swine. Page 179, "The addition of charcoal (to water) may bring about a reduction in total volume of as much as 25 per cent." The reviewer was unable to verify this statement. Page 193, "Air contains approximately 140 gamma of iodine per liter." The reviewer believes such an amount would be distinctly visible, and highly toxic. The statement could not be verified. Page 219, "The neutral sodium phosphate, Na_2HPO_4 . . ." The titration curve of a 0.1 M solution of phosphoric acid indicates that the pH of the di-sodium salt is over 9, decidedly alkaline. Page 271, the discussion of vitamin D contains no intimation that ergosterol is not the only provitamin D.

In connection with the discussion of obesity on page 132, the author deprecates attempts to remedy the condition before the cause is established. Everyday experience indicates that it may be inadvisable to wait that long.

A. G. HOGAN

American Foundations for Social Welfare—Compiled by Russell Sage Foundation Library, Bertha F. Hulsemann, Librarian. New York: Russell Sage Foundation, 1938. 66 pp. Price, \$.50.

This pamphlet lists 157 foundations interested in promoting social welfare, giving information as to how they came to be established, the amount of money involved, the purposes they are designed to serve, and the names of executive officers. In addition 31 community trusts are listed. The foundations are listed alphabetically and according to their principal interest. The pamphlet has been revised as of April, 1938, and should be of value to anybody interested in a particular foundation as well as to those who wish to find out what foundations are active in any special field, such as regional planning or eugenics.

CATHERINE GROVES PEELE

Das Leben der Frau—By Bruno Gebhard, M.D. Stuttgart: Union Deutsche Verlagsgesellschaft, 1937. 232 pp., 107 ill.. Price, \$5.00.

From the pen of a well recognized leader of those who are attempting to guide the public through the maze of modern scientific knowledge it is not surprising that this volume is an unusually straightforward, readable, and simple account of the problems of women from puberty to old age. Dr. Gebhard, known chiefly to American public health workers for his contributions to the German Hygiene Museum in Dresden and now as a consultant to the New York World's Fair Committee, has proved himself to be proficient in presenting facts by the printed word as well as by the exhibit. His use of the visual method has nevertheless added greatly to the attractiveness of the present volume in supplying 107 graphs, diagrams, photographs, and drawings—a most interesting collection.

The subject material covered is varied—anatomy, physiology, psychology, sociology, religious attitudes, political movements and how they may influence the development, status and rôle of the woman of today. Courtship, marriage, divorce, menstruation, pregnancy, motherhood, care of children, menopause, the unmarried woman—all are discussed frankly and simply—in terms which any woman should understand and from a point of view which does not isolate her but links her effectively to all phases of modern life.

The author has chosen from the many theories of the day a sensible one which will satisfy the needs of the woman who wishes to know what modern science seems to know about her.

The scientific reader will probably wish that Dr. Gebhard had somewhere tucked in a bibliography—or at least given the sources for some of his interesting statistics—but let him be content to learn how to state his facts

lucidly and, if his German is not very fluent, be happy that Dr. Gebhard has not written that language in a style which is difficult for English readers.

LEONA BAUMGARTNER

Successful Living—By W. Béran Wolfe. New York: Farrar & Rinehart, 1938. 180 pp. Price, \$2.00.

Human beings, contends Dr. Wolfe, may be the "captains of their souls" so far as happiness is concerned; even the blows of destiny are alleviated through a correct psychological approach to the problems involved. By means of an ingenious illustration termed the "Wheel of Life," one quickly learns (or suspects) that he is infantile, adolescent, or mature in outlook; average or superior in intelligence. Then, through the author's stimulating suggestions, one can work out his own problems which may involve social maturity, leisure time, sex, education, health, religion, dress, politics, culture, vital philosophy, self esteem, marital and family relationships, failure, etc. The result may convince one that what is laid to cruel and heartless destiny, may originate in one's own ignorance and lack of coöperation.

Thus, we may either "muddle through," which for the author is a matter of accepting life as it is—suffering when it is hard, enjoying it when it is pleasant, meeting or evading difficulties when they appear—or we may become more objective in our relationships. He grants that a completely objective human being does not exist, except as a really great hero, but this, of course, is no excuse for attempting to evade the adjustments forced on us by the compulsion of intelligence.

This book is to be recommended as a good investment, at least as an adjunct for mental pruning equipment, and it is of a high degree of useability for men and women in active life.

N. M. GRIER

Swimming and Diving—By *American Red Cross*. Philadelphia: Blakiston's, 1938. 271 pp. Price, \$.60.

Following a brief history of swimming and the development of different styles of swimming, this text discusses in turn learning how to swim, covering such factors as floating, turning, and stroking, and then takes up the elements of swimming, discussing the technics of various styles and strokes. Each type of stroke is described in

considerable detail. About one-third of the text is devoted to the history, style, and technic of diving.

This is an excellent text. The various procedures are carefully described in an interesting manner. Numerous illustrations add to its value. It might well be a part of the library of any instructor in physical education whether or not actually engaged in the teaching of swimming.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

State Medicine Bogey Interred—Editorializing upon the twenty-five year progress of health insurance in Great Britain, the gains in people covered and stability of finances are enumerated. Another important step is the provision of postgraduate training of insurance doctors. Despite the fear that health insurance would degrade medical practice, experience has shown it to have the opposite effect. Increase in drug prescribing is decried.

ANON. *The Progress in Health Insurance.* *Lancet.* 2, 8:439 (Aug. 20), 1938.

Why Women Worry—If we are to believe the picture drawn by this British gynecologist, the average woman's life must be pretty dreadful. In adolescence she suffers from fears and disappointments; her business career may be difficult and unhygienic; her childbearing may leave impaired sex organs because postnatal supervision is often neglected or superficial; menopause brings new grief: infirmities of old age close this gloomy picture.

BOURNE, A. *Influences Which Undermine the Health of Women.* *J. Roy. San. Inst.* 1, 12:705 (Sept.), 1938.

Cheers for Engineers—After recounting the contributions of the engineer to public health in the usual fields of accident prevention, public sanitation, housing and nutrition, the author points to the still greater contributions that engineers may make. Worry, he says, has wrecked more lives than tuberculosis has. Economic insecurity is the great cause of worry. More stable industry, which engineers will some day effect, will cure the condition.

DAVIS, H. N. *Engineering and Health.* *Sci. Month.* Oct., 1938, p. 328.

Mind Over Matter Department—These researchers gave some "cold-susceptible" students cold vaccines; to others they gave injections of saline, but let them think they were getting vaccine. You have guessed it! Both groups were helped greatly and about equally. Some who received the saline were helped so much, in fact, that they went the next season to the family physician for repeat "vaccine" treatments.

DIEHL, H. S., *et al.* *Cold Vaccines.* *J.A.M.A.* 111, 13:1168 (Sept. 24), 1938.

For the First Time, a National Health Program—Good reporting that catches the spirit of the recent National Health Conference held in Washington, which found public health services grossly insufficient, institutional facilities inadequate, a third of the population receiving little or no medical care, and even more Americans suffering from burdens created by illness.

HALL, H., and KELLOGG, P. *The Unserved Millions.* *Survey Graphic.* 27, 9:437 (Sept.), 1938.

Drinking Drivers Cause Accidents—Interesting research is reported in the field of drinking and driving. If you are carrying the equivalent of 0.5 parts of alcohol per thousand or less in your blood, you are not more likely to cause an accident than if you had not had a drink. Greater concentration of alcohol increases your liability to driving accidents. Most drinking-driving occurs in the wee small hours, especially at the

week-end, and alcohol is a major cause of automobile accidents.

HOLCOMB, R. L. Alcohol in Relation to Traffic Accidents. J.A.M.A. 111, 12:1076 (Sept. 17), 1938.

Milk for Premies—How 4,000 quarts of breast milk were procured, pasteurized, preserved, and dispensed in New York City. Statistics about the other nine municipal milk stations are given. If human milk were everywhere available, it is suggested that most premature baby deaths could be prevented.

LAWS, C. H., and SKELLEY, E. G. A Maternal Milk Laboratory. Am. J. Nurs. 38, 8:859 (Aug.), 1938.

Toward the Control of Cancer—Evidence of the value of the Massachusetts cancer program is found in the reduction of the adjusted cancer death rate for women which has taken place since the project started; in the lessening of the average time between first symptoms and the institution of treatment, and the marked increase in the number of physicians using the diagnostic services.

MACDONALD, E. J. The Evolution of Cancer Control in Massachusetts. Med. Woman's J. 65, 9:264 (Sept.), 1938.

Pediatricians Please Note—If cow's milk disagrees with the baby, try adding dehydrated apple to the formula; less hydrochloric acid is needed and a soft curd is assured.

REITHEL, F. J., and MANVILLE, I. A. Adv-

vantages of Adding Apple to Milk Formulas. Am. J. Dis. Child. 56, 2:235 (Aug.), 1938.

When Pregnancy Complicates Tuberculosis—At least 30,000 tuberculous women become pregnant every year. What to do about them? Mostly it depends upon the condition of the mother, the facilities for prenatal care, the disposition of the baby. The prospect isn't a pretty picture, for a third of the mothers die within a year of delivery: good obstetrical care, or therapeutic abortion could improve the situation.

SKILLER, J., and BOCES, E. Pregnancy and Tuberculosis. J.A.M.A. 111, 13:1153 (Sept. 24), 1938.

Neonatal Deaths—Reviewing the cause of death of all the children who died among those born in New York State in 1936, it was found that the first-born and those high in order of birth had a higher neonatal mortality than the "in-betweens." More than half the neonatal deaths were among "premies," the rate being twenty-five times as high as among full-term infants. Boy babies had a higher neonatal mortality than girls, and very young or old mothers had more trouble in this regard and in the matter of stillbirths than those between twenty and thirty years. The age of the father, too, influenced neonatal mortality. Conclusion jumpers will find this article much to their liking.

YERUSHALMY, J. Neonatal Mortality by Order of Birth and Age of Parents. Am. J. Hyg. 28, 2:244 (Sept.), 1938.

ASSOCIATION NEWS

OFFICERS, 1938-1939

President, ABEL WOLMAN, DR.ENG., Baltimore, Md.

President-elect, EDWARD S. GODFREY, JR., M.D., Albany, N. Y.

First Vice-President, A. GRANT FLEMING, M.D., D.P.H., Montreal, Que., Canada

Second Vice-President, LEONIDES ANDREU ALMAZAN, M.D., Mexico City, D. F., Mexico

Third Vice-President, EDWIN H. SCHORER, M.D., DR.P.H., Kansas City, Mo.

Treasurer, LOUIS I. DUBLIN, PH.D., New York, N. Y.

Chairman of Executive Board, JOHN A. FERRELL, M.D., DR.P.H., New York, N. Y.

The Annual Meeting in 1939 will be held in
Pittsburgh, Pa.

Sedgwick Memorial Medal Awarded Wade Hampton Frost, M.D.

ON behalf of the Sedgwick Memorial Medal Committee, the following announcement was made by Dr. Haven Emerson at a General Session of the American Public Health Association meeting at Kansas City on October 25.

"The Sedgwick Memorial Medal, awarded in 1938 to Dr. Wade Hampton Frost, was given to him in Baltimore on April 11 through the hands of his wife. Swift and irreparable disease which soon after took Dr. Frost upon his last journey deprived us of that opportunity to express in his presence the full measure of our respect and affection for him, to which this moment in our proceedings is devoted.

"Born as it were in the midst of medical practice, and fortunate in the foundations in his chosen profession, his gifts of character and intellect combined with the instincts of the scholar to mark his work and influence with distinction.

Wade Hampton Frost, M.D.

"His rigorous honesty of approach and a fine scorn for any other facts than those of enduring worth, drew to him students and colleagues who cherished

the gentle persuasiveness and the judicious encouragement of his helpful criticism. His readiness to lose himself in looking through and beyond the problems of all who came seeking the generosity of his attention was notable.

"While his illuminating contributions in the fields of poliomyelitis, influenza, diphtheria, and tuberculosis stand high among the classics of epidemiology, perhaps his planning, direction, and scientific guidance of the stream pollution laboratory at Cincinnati will prove to have been his most abundant legacy to the expanding fields of the theory and practice of public health.

"And yet the breadth of influence which was his can be measured best by other products than his publications or his administrative services, pregnant as these were with creations of his thought and industry.

"As the spirit of Sedgwick carries along now in the second generation a strong current of pure biology and applied sanitation through the lives of his former students and their disciples, so we have here among us, and know in many a foreign land, of the army of young men and women whose thoughts have been made broader, yet more precise, and whose hearts have been

touched by the warm nobility, and their lives by the distinctive superiorities of mind and manner of Wade Hampton Frost.

"He all but created for this country, and our generation of servants of the public health, the scientific discipline and the productive study of epidemiology. He inevitably, and all but unconsciously, put every member and Fellow of our Association under permanent obligation for the clarity of his thought and the beautiful simplicity and directness of expression with which he clothed the studies he made and the conclusions he wisely drew from them.

"We should each add honor to our respective profession and keep alive among our successors at least part of the lives of Sedgwick and Frost if we could capture and use in our own days' work some of their rare and precious qualities.

"Integrity of purpose and method in all his work, intellectual power of rare and extensive scope, a pervading courtesy in every human relationship—for these alone of his many fine qualities Dr. Frost will be remembered with enduring affection by all who knew him personally or only by his written words."

Statement of Dr. Leonides Andreu Almazan, Director of Public Health, Federal Department of Health, Mexico City, D. F.,
for presentation at the Second General Session of the
Sixty-seventh Annual Meeting of the A. P. H. A.,
October 27, 1938

IT is indeed a great honor for the public health authorities of Mexico to have received the gracious invitation of the American Public Health Association to attend this convention, and I beg to convey to you the cordial greetings of President Lazaro Cardenas and of my colleagues and collaborators of the Public Health Services of Mexico.

One of my collaborators will explain to you in detail, at some opportune moment, the different activities and advancements made in public health and sanitation in Mexico by the Federal Health Department under my direction.

For the moment, I wish to report our grateful appreciation of the helpful co-operation which the Rockefeller Foun-

dation has extended to Mexico in public health problems and in granting fellowships in the universities of the United States for the training of health personnel—health officers, sanitary engineers, and public health nurses—as well as in detailing to Mexico its representatives, Drs. Bailey and Earle, to coöperate with the Mexican Government in dealing with its health problems. I wish to express my sincere and grateful appreciation and also that of my government to this philanthropic Foundation for its valuable coöperation in improving the well-being and prosperity of my country.

As to the most important activities of our program for the coming year, I might mention

1. The improvement of existing potable water supply systems and creation of new systems in as many rural areas as possible, aiming to reduce the mortality due to water-borne diseases.

2. Increasing the campaign for the relief and control of malaria, a disease which causes a great deal of illness in Mexico, and for which there will be appropriated the sum of three million pesos.

3. Creating a tuberculosis consciousness in the entire country and intensifying and coördinating our activities for the relief of this plague. Organizing a committee to solicit private coöperation to aid the official agencies.

4. We are giving consideration and sympathetic aid to this great country in the campaign for the control of narcotics and addicts and in preventing criminal activities resulting from smuggling of narcotics into the United States.

In conclusion, I wish to convey to the American Public Health Association my sincere hope that this convention may be most successful in its efforts for the benefit of mankind the world over.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Robert J. Alexander, M.D., 2033 S. State St., Salt Lake City, Utah, County Physician
Norman G. Angstadt, M.D., New Martinsville, W. Va., Director, Wetzel County Health Dept.
Charles H. Bondurant, M.D., Wytheville, Va., Wythe County Health Officer
A. Frank Brewer, M.D., C.P.H., Solano County Health Dept., Fairfield, Calif., Director
Watkins A. Broyles, M.D., Bethany, Mo., Deputy State Commissioner of Health
Wallace E. Childs, M.D., M.P.H., 226 W. Broadway, Princeton, Ind., Director, District Health Dept. No. 1, State Board of Health
James O. Hood, M.D., 420 E. Keith, Norman, Okla., Director, Cleveland County Public Health Unit
William C. Hunsicker, M.D., 1625 Race, Philadelphia, Pa., Director, Dept. of Public Health

Samuel B. Johnson, M.D., Box A, Franklin, W. Va., Pendleton County Health Officer
Henry W. Kassel, M.D., City Hall, Kansas City, Kans., Assistant Director of Health
E. E. McDaniel, D.O., Cassville, Mo., County Physician
Carlos M. Patterne, Dept. de Sanidad, Mayaguez, P. R., Chief Inspector
Elihu F. Sloan, M.D., Columbiana, Ala., Shelby County Health Officer
Lawrence C. Snow, M.D., Medical Arts Bldg., Salt Lake City, Utah, Assistant County Physician
Thomas G. Ward, M.D., St. Joseph, La., Director, Tensas Parish Health Unit
Burton L. Zinnamon, M.D., Sonoma County Health Dept., Santa Rosa, Calif., Health Officer

Laboratory Section

Alonzo T. Barrett, 2534 Brinker Ave., Ogden, Utah, City Bacteriologist
Parker R. Beamer, 362 Chemistry Building,

Urbana, Ill., Bacteriology teacher, University of Illinois

Thelma E. DeShazo, 412 E. 5th, Austin, Tex., Field technician, State Dept. of Health

Justus Goslau, M.D., Cedar Grove, N. J., Chemist and Bacteriologist, Division of Water (Newark)

Gertrude McGrath, 1030 Rowland Ave., Kansas City, Kans., City technician

William M. Moody, M.D., 2109 Clifton Ave., Cincinnati, O., Bacteriologist, Health Dept.

Hildrus A. Poindexter, M.D., Ph.D., Howard University, School of Med., Washington, D. C., Professor of Bacteriology, Preventive Medicine and Public Health

Dorothy Rodgers, 410 E. Capital Ave., Jefferson City, Mo., Laboratory technician, State Dept. of Health

Lila E. Suiter, Santa Maria Hospital, Santa Maria, Calif., Bacteriologist and Laboratory technician

Vital Statistics Section

Henry W. Gibbons, M.D., 930 J St., Sacramento, Calif., Medical Director, California Western States Life Ins. Co.

Claud C. Ham, 603 Decatur N.W., Washington, D. C., Associate Statistician, Social Security Board

Elizabeth H. Pitney, Yale School of Medicine, New Haven, Conn., Graduate Student, Dept. of Public Health

David M. Wolfe, M.D., C.P.H., State Dept. of Health, Atlanta, Ga., Assistant Director, Bureau of Vital Statistics

Public Health Engineering Section

Frederick A. Brown, Los Lunas, N. Mex., District Sanitarian, State Dept. of Public Health

Paul D. Haney, State Board of Health, Lawrence, Kans., Chemical Engineer, Div. of Sanitation

George K. Hendrix, Box 161, Carbondale, Ill., Sanitary Engineer, State Dept. of Public Health

Arthur D. Jackson, Jr., Lee County Health Dept., Jonesville, Va., Sanitation Officer

James M. Jarrett, State Board of Health, Raleigh, N. C., Consultant in Sanitary Engineering

Benedict A. Lacombe, Echo, La., Sanitary Inspector, Desota Health Unit

Paul Lange, 812 Grove St., Emporia, Kans., Sanitarian, Lyon County Health Dept.

Maurice LeBosquet, Jr., 516 New Post Office Building, Chicago, Ill., Associate Public Health Engineer, U. S. Public Health Service

Felix C. Pickron, P. O. Box 88, Damascus,

Ga., Assistant District Supervisor, U. S. Public Health Service

Blucher A. Poole, 201 State House Annex, Indianapolis, Ind., Chief Engineer, State Board of Health

Abram Pratt, 823 McVicar Ave., Topeka, Kans., District Supervisor, U. S. Public Health Service

Clement L. Richardson, State Board of Health, Jacksonville, Fla., State Shellfish Inspector

Milo R. Simmonds, Antlers, Okla., Assistant Sanitary Engineer, State Dept. of Health

Industrial Hygiene Section

Beatrice Mintz, M.D., 27 W. 96 St., New York, N. Y., Associate Industrial Hygiene Physician, Division of Women in Industry, New York State Labor Dept.

Kenneth M. Morse, 1800 Fillmore, Chicago, Ill., Industrial Hygiene Engineer, State Dept. of Public Health

Harold H. Steinberg, M.D., 3907 W. Gladys Ave., Chicago, Ill., Industrial Hygiene Physician, State Dept. of Public Health

Food and Nutrition Section

Glenn E. Merrill, Dept. of Public Welfare, Wichita, Kans., Chief Milk Inspector

Child Hygiene Section

Gertrude E. Cromwell, Room 10, City Hall, Des Moines, Ia., Supervisor, Health Education and School Nursing, Public Schools

Bess W. LeFevre, 132 E. Como St., Columbus, O., Nursing Consultant, State Dept. of Health

Vernon W. Lippard, M.D., 303 Ninth Ave., New York, N. Y., Director, Commission for Study of Crippled Children

Roland H. Loder, M.D., 1003 State Capitol Bldg., Lincoln, Nebr., Director, Division of Maternal and Child Health, State Dept. of Health

Katherine M. Schweikart, Cambrian Hotel, Jackson, O., Field Nursing Consultant, State Dept. of Health

Howard Workman, M.D., Hermann, Mo.

CORRECTED IDENTIFICATION OF MOSQUITO IN CHINA CLIPPER

IN our issue of September, 1938, page 1117, we stated that "In August, 1937, a living *Anopheles maculipennis* was found in a Chinese Clipper arriving at Honolulu from Alameda, Calif." This was taken from an official report by Surgeon General Hugh S. Cumming to the Permanent Committee of the Office International d'Hygiene Publique

in March, 1938. We have just received a letter from Harold Farnsworth Gray, Engineer and Executive Officer of the Alameda County Mosquito Abatement District, Oakland, Calif., saying that this specimen was sent to the National Museum in Washington, D. C., and authoritatively identified as being *Theobaldia incidens*.

PUBLICATION NEEDED

THE Association stock of the January, 1938, issue of the *American Journal of Public Health* is exhausted. The Association office will gladly

pay postage on any copies which members or subscribers can supply. Address: 50 West 50th Street, New York, N. Y.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Nurse Placement Service, 8 South Michigan Avenue, Chicago, Ill., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS WANTED

HEALTH OFFICERS

Physician, M.D., Class A medical school; M.P.H., Harvard School of Public Health; extensive experience in pediatrics and school medical services; also background of county health administration and teaching in medical school, will consider expanded opportunity in teaching or research. A302

Physician, with Dr.P.H. degree from Yale, now employed by state department of health, will consider position in general health administration, in infant welfare or in epidemiology. A300

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, M.D., University of Virginia; excellent background, seeks position as health officer in well organized health department. A388

Physician, M.D., Class A medical school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer, seeks full-time administrative position in city or county. A367

Physician, experienced in health administration of cities and states, will consider attractive opening in maternal and child health or health education. A343

Well qualified physician, with C.P.H. from Johns Hopkins; experienced as school physician and in college teaching, will consider city or county administrative position or teaching and student health service. A383

Physician, M.D., University of Cincinnati; with post-graduate training in venereal disease control, Johns Hopkins; now employed, is available as venereal disease control officer. A363

Physician, M.D., C.P.H., two years' experience as district health officer; anxious to

do venereal disease control work or epidemiology. A345

Physician, M.D., A.B., 30 years city health department. Administrative, educational and research experience; also familiar with venereal disease work. A295

Physician, age 34; M.D., University of Wisconsin; M.P.H., Harvard; specializing in industrial hygiene, will consider general administration. A342

Physician with Dr.P.H. degree, experienced as a local health officer, in present position since 1929, will consider opening. A386

HEALTH EDUCATION

Well qualified woman in health education wishes position as health coördinator or health counselor. Has wide experience, and Ph.D. from New York University. H236

Young woman, M.A., Health Education, Teachers College, Columbia University; with splendid international experience, seeks position as director of health education with preference for New York City. H369

Young woman, M.S.P.H., University of Michigan, experienced in laboratory research and health education, is available for research or investigative work. H303

Woman, M.D., Boston University; special work Columbia and Massachusetts Institute of Technology; one year's experience in state hospital; interested in psychiatry, desires position in the east in hospital for mental diseases or industrial school. H247

MATERNAL AND CHILD HEALTH

Woman physician, graduate of University of Iowa, who has directed state bureau of maternal and child health, now employed, will consider another position. C318

Woman physician, with excellent medical training and background of public health nursing experience, seeks position in maternity and infancy work. C376

(Continued on page 1364)

LABORATORY

Bacteriologist and pathologist with wide administrative experience; Ph.D., Brown University; will consider leading position in this field. L371

Experienced laboratory director with background of dairy products manufacture and research in control methods; University of Wisconsin, M.S. and Ph.D.; desires administrative position with food manufacturing or processing industry, or association with health department doing routine and research work in food control. L381

Capable research worker, Ph.D., trained at University of Southern California, seeks position directing laboratory, in research work or field investigation. Has taught bacteriology, directed state hygienic laboratory and hospital laboratories. L315

Young woman, A.B., Bates College; several years' experience in various state laboratories, desires position as bacteriologist. L253

Bacteriologist with training at C. C. N. Y., N. Y. U. and Cornell Medical College, wishes laboratory position in bacteriology; east or southwest. M351

Young woman, A.B., major in bacteriology; nine years' experience; now employed in a clinical laboratory; desires position in bacteriology or serology in a health department laboratory or in research. L382

Laboratory technician; B.Sc. degree; with experience in Army, state public health laboratory, and U. S. Public Health Service field laboratory, seeks position in medical school or university. L379

Bacteriologist and serologist, A.B., University of Kansas; at present bacteriologist in charge, public health laboratory; will consider another position. L390

SANITARY ENGINEERING

Graduate sanitary engineer with service under U.S.P.H.S. and state departments of health, especially interested in filtration plant design and operation and shellfish sanitation, seeks employment. E356

Sanitary Engineer, courses at Rutgers University, with 17 years' experience in design, research and construction of water and sewage plants, as well as aerial pollution surveys, desires position, preferably research. E321

Public health engineer, B.S. in Sanitary Engineering from Massachusetts Institute of Technology, experienced in Massachusetts, Connecticut and Kentucky, seeks position as sanitary or public health engineer with health department. E380

Experienced sanitary engineer, graduate of Massachusetts Institute of Technology, seeks responsible position. E372

MISCELLANEOUS

Young man, age 27, S.B., Massachusetts Institute of Technology; A.M., Boston University; M.S. in Biochemistry, University of Michigan; 2 years' graduate work in public health; experienced in chemical, bacteriological and biochemical research; teaching experience in college hygiene, desires a position in a food industry involving research or control. M374

Physician, graduate of Johns Hopkins Medical School, and well qualified in medicine and tuberculosis, will consider a clinical position in the medical field. M377

Experienced teacher in bacteriology and public health, Ph.D., Cornell; now professor in Grade A medical school, will consider teaching, executive or administrative position. M327

Young woman, B.S. in Education, University of Pennsylvania; four years' experience in medical and vital statistical research; knowledge of typing and shorthand, desires position as statistical research assistant. Excellent references. S389

Dentist, graduate of Temple University, with excellent post-graduate experience, desires position in administrative aspects of dental hygiene. M352

Experienced public health nurse executive, Fellow A.P.H.A., is available for responsible position. N384

NEWS FROM THE FIELD

PUBLIC HEALTH FELLOWSHIP FOR WOMEN

THE American Association of University Women announces a public health fellowship for women.

The Mary Pemberton Nourse Memorial Fellowship in Public Health, of the value of \$1,250, will be awarded for the academic year 1939-1940. Applications for this fellowship are due on December 15, 1938.

Women applying for the fellowship must possess a bachelor's degree or its equivalent. They must also have completed a minimum of either two years of graduate study tending toward public health work (for instance in such subjects as biology, chemistry, the medical sciences, economics, sociology), or two years of practical work in the field of public health. Preference will be given to those candidates who have completed two years of residence work for the doctorate or who have already received the degree.

The fellowship may be used for any work along the lines of public health work which shall be approved by the committee.

In the letter of application, the applicant for this fellowship must explain fully her conception of public health work. Correspondence should be addressed to: Secretary, Committee on Fellowship Awards, American Association of University Women, 1634 I Street, N.W., Washington, D. C.

NURSING INFORMATION BUREAU

THE Nursing Information Bureau of the American Nurses' Association, 50 West 50th Street, New York, N. Y., has issued two folders entitled "Wanted—A Real Nurse, an R.N.," and "Safe Nursing Care and Where

To Ask for it." They discuss briefly the significance of the term "Registered Nurse" and suggest how to secure professional or other types of nursing service when needed. Any one may secure these folders from the Nursing Information Bureau.

NEW DEPARTMENT IN LOYOLA

EARL E. Kleinschmidt, M.D., Dr.P.H., the Director of the Department of Preventive Medicine, Public Health and Bacteriology at Loyola University School of Medicine, Chicago, has announced the establishment of a new Department offering courses leading to the Certificate and Bachelor of Science degree in Public Health Nursing, the Master's degree in Public Health for graduate students, courses in Preventive Medicine for medical students, and advanced Bacteriology. Associated with Dr. Kleinschmidt in the department will be John H. Bailey, M.D., recently with the University of Illinois Medical School; Dr. Klimek from the University of Michigan; Dr. Robert Lee, Associate in charge of Student Health Service; Margaret Cleary, and Mrs. M. Roessler, in charge of Public Health Nursing.

VOLUNTEER BLOOD DONORS BUREAU

THE Baltimore Red Cross has undertaken the establishment of a Transfusion Bureau aimed to supplement other facilities in the community and to supply the deficit in the transfusion requirements through the volunteer services of donors.

An outline of the provisions set up for Baltimore can be secured from Charles C. W. Judd, Director of the Blood Transfusion Bureau, 202 Guilford Avenue, Baltimore, Md.

PERSONALS

Central States

HARRY V. GIBSON, M.D.,† Health of the Eau Claire, Wis., County Health Unit, has been appointed Health Officer of Great Falls and Cascade County, Mont.

MINA B. GLASIER, M.D.,† of Bloomington, Wis., recently resigned as a member of the Wisconsin State Board of Health after 14 years of service. She served as President of the Board in 1935 and as Vice-President in 1937.

PERCY L. HARRIS, M.D.,† of Columbus, Ohio, a member of the staff of the Ohio State Department of Health, has been appointed Health Commissioner of Portage County, succeeding DR. ROLLIN D. WORDEN, resigned.

MILTON E. PARKER,* of the Beatrice Creamery Company, Chicago, Ill., has been appointed Director of the American Dairy Science Association for 3 years.

DR. HERMAN M. SOLOWAY, of Chicago, has been appointed Venereal Disease Control Officer of the Illinois State Department of Health. The newly created post was made possible by funds allotted to the state by the U. S. Public Health Service.

DR. ROLLIN D. WORDEN, of Ravenna, Ohio, resigned September 1 as Health Commissioner of Portage County.

Eastern States

THOMAS FRANCIS, JR., M.D.,† of the International Health Division of the Rockefeller Foundation in charge of research on influenza, has been appointed Professor of Bacteriology in the New York University College of Medicine.

DR. WILLIAM SHERMAN RANDALL has been appointed Health Officer of Shelton, Conn., to complete the un-

expired term of the late DR. J. EUGENE BLACK.

Southern States

CHARLES H. BONDURANT, M.D.,† of Wytheville, Va., has been made Health Officer of Wythe County.

DR. LUTHER A. BRENDLE, of Clinton, Tenn., has been appointed Health Officer of Dodge County, succeeding DR. JOHNNIE L. GALLEMORE, of Eastman, resigned.

EDWIN CAMERON, M.D.,† of Baltimore, Md., has been appointed Health Officer of Monongalia County.

ROBERT L. CHERRY, M.D., C.P.H.,† of Kaufman, Tex., Director of the District 3 Health Unit of the Texas State Department of Health, has been appointed Health Officer of the Tyler-Smith County Health Unit, to succeed AUSTIN E. HILL, M.D.,† of Tyler.

CHADWICK W. CHRISTINE, M.D.,† of Louisville, Ky., has been appointed Health Officer of Mason County to succeed OLLIE M. GOODLOE, M.D., C.P.H.,† resigned.

ROBERT P. COOKE, M.D.,† of Lexington, Va., continues as Health Officer in the health unit formed as a result of the recent separation of Rockbridge County from the Alleghany-Botetourt-Rockbridge Health District to be joined in one unit with the City of Lexington.

DR. DAVID M. COWGILL,* of Madisonville, Tenn., Health Officer of Monroe County, has been appointed Director of the Giles County Health Unit, succeeding J. W. ERWIN, M.D.,† of Pulaski, who has been appointed in Washington County.

JAMES NICHOLAS DUDLEY, M.D.,† formerly of Eastville, Va., has been appointed Health Officer for the Farmville district, made up of Prince

* Fellow A.P.H.A.

† Member A.P.H.A.

Edward, Buckingham, and Nottoway Counties.

WILLIAM Y. GARRETT, M.D.,† of Raven, Va., has succeeded JAMES NICHOLAS DUDLEY, M.D.,† as Health Officer of Northampton County.

OLLIE M. GOODLOE, M.D., C.P.H.,† of Maysville, Ky., has resigned as Health Officer of Mason County, to become Field Director of the State Board of Health for Eastern Kentucky, with headquarters in Lexington.

JAMES H. GORDON, M.D.,† of Covington, Va., has been appointed Health Officer of the new district of Alleghany and Botetourt Counties.

DR. FERDINAND R. HASSLER, JR., formerly of Oklahoma City, Okla., has been appointed Director of a new city and county health unit in Muskogee and Muskogee County.

AUSTIN E. HILL, M.D.,† of Tyler, Tex., has been appointed Director of Communicable Diseases, Epidemiology, and Maternal and Child Health in the Health Department of Houston.

JAMES O. HOOD, M.D.,† of Norman, Okla., has been appointed Health Officer of Cleveland County to succeed GUY H. WILLIAMS, M.D.

ROBERT L. HUNTER, M.D.,† of Whitesville, W. Va., Health Officer of Boone County, has been placed in charge of a new Coal River District that includes Boone and Lincoln Counties.

DR. ROBERT R. KING, of Boone, N. C., has been appointed District Health Officer in a new district made up of Ashe, Alleghany, and Watauga Counties.

BOLIVAR J. LLOYD, M.D.,† of Washington, D. C., Medical Director, U. S. Public Health Service, retired, has been appointed Director of a recently organized health unit for Austin, and Travis County, Tex.

OTIS R. LYNCH, M.D.,† of Brandenburg, Ky., has resigned as Health

Officer of Meade County, to enter private practice in Marengo, Ind.

HUGH C. McREE, M.D.,† formerly Health Officer of Lee County and recently engaged in special work under the supervision of the Bureau of Preventable Diseases of the Alabama State Department of Health, has been appointed Health Officer of Marion County, effective September 15, succeeding THOMAS L. OWINGS, M.D., of Hamilton, resigned.

BENJAMIN O. MORRISON, M.D.,† of Abbeville, La., has been appointed Health Officer of Acadia Parish.

DR. WILLIAM BRUCE NELSON, of Fairfield, Ala., has been appointed Health Officer of Baldwin County, to succeed DR. ARTHUR J. VANDERGRIND, of Bay Minette, who has resigned to accept a commission in the U. S. Army Medical Corps.

BENJAMIN M. PRIMER, M.D.,* recently Health Officer of Amarillo, and Potter County, Tex., has been made Assistant to the Director of a recently organized health unit for Austin, and Travis County.

DR. EUGENE BOWIE SHEPHERD, of Baltimore, Md., has been appointed Assistant Health Officer of Pittsylvania County, Va.

DR. CLARENCE H. WHITE, of Burnsville, N. C., District Health Officer for Avery, Watauga, Yancey and Mitchell Counties, has been appointed Health Officer of a new unit in Catawba County.

Western States

DR. JACKSON L. SADLER, of Denver, Colo., Assistant Director of the Maternal and Child Health Division of the Colorado State Board of Health, has resigned to enter private practice in Fort Collins.

* Fellow A.P.H.A.

† Member A.P.H.A.

Canada

DR. RANDOLPH J. GIBBONS, formerly Assistant to the Director of the Connaught Laboratories, University of British Columbia, Vancouver, has been appointed Chief Bacteriologist to the Laboratory of Hygiene, Department of Pensions and National Health.

DR. PIO H. LAPORTE, of Edmundston, has been appointed Minister of Health and Labor in the Government of New Brunswick.

DR. JOHN W. McINTOSH,† Medical Officer of Health of Vancouver, B. C., retired from that position September 30.

Puerto Rico

EDUARDO GARRIDO-MORALES, M.D., DR.P.H.,* of San Juan, has been re-appointed Commissioner of Health of Puerto Rico for a term of 4 years.

DEATHS

HENRY MARTYN BRACKEN, M.D., Secretary and Executive Officer of the Minnesota State Board of Health from January 12, 1897, to September 1, 1919, died September 25, 1938, at his home in Claremont, Calif., in his 85th year. Upon retirement as State Health Officer, in 1919, Dr. Bracken was commissioned in the Reserve Corps of the U. S. Public Health Service as Surgeon, with rank equivalent to that of Lieutenant Colonel in the Army, and assigned to the Veterans' Bureau. In 1923 he resigned and moved to California, where he was actively engaged in public health work in Los Angeles City and County.

FRANK W. LAIDLAW, M.D.,* of Middletown, N. Y., District Health Director and Dean of the New York State Department of Health field personnel, died September 20. For over 20 years, Dr. Laidlaw was District

Health Officer with jurisdiction over the Middletown district involving general supervision of the work of more than 70 health officers. At the time of his death, he had direct supervision of Sullivan, Orange, and Rockland Counties and of the sub-district composed of Ulster and Greene Counties. Since 1936, when he was promoted to the position of District Health Director, he had had in addition general supervisory jurisdiction over the districts in the eastern upstate area.

ERNEST COLEMAN LEVY, M.D.,* of Richmond, Va., died September 29, at the age of 70. Dr. Levy was formerly Chief Health Officer, and later Director of Public Welfare, of Richmond. For 3 years he was Health Officer of Tampa, Fla. Dr. Levy served as House Physician at Mount Sinai Hospital in New York from 1890 to 1892, and from 1897 to 1900 was a Professor at the Medical College of Virginia. At the same time he was Editor of *The Medical Register*. In 1925 he returned to the Medical College of Virginia to teach preventive medicine. During the World War he made original investigations in the origin of Southern typhoid fever, and was known for his study of the breeding and control of the house-fly, which resulted in the invention in 1911 of the maggot trap. He had also conducted research in infantile diarrhea. He was President of the American Public Health Association in 1923.

RICHARD M. OLIN,* Director of Health Service, Michigan State College, East Lansing, Mich., died October 4. He became a member of the American Public Health Association in 1915, and a Charter Fellow in 1922.

A Century in Arrears*

ABEL WOLMAN, DR.ENG., F.A.P.H.A.

President, American Public Health Association; Professor of Sanitary Engineering, Johns Hopkins University, Baltimore, Md.

EXACTLY one hundred years ago the Poor Law Commissioners of England recommended that the Poor Law Act should be so amended as to provide for expenses which resulted from disease by which the poor were reduced to destitution. The Commissioners stated: "In general, all epidemics and all infectious diseases are attended with charges, immediate and ultimate, on the poor rates. Laborers are suddenly thrown by infectious diseases into a state of destitution, for which immediate relief must be given." They further recognized that "The amount of burdens thus produced is frequently so great as to render it good economy on the part of the administrators of the poor laws to incur charges for *preventing* the evils . . ."

Thus a century ago, as Sir John Simon accurately phrased it, "Health necessarily began to take rank as an object of practical politics." No one reading the history of English sanitary

institutions can escape the conclusion, however, that the practical acceptance of this axiom was beset with continuing difficulties. During the past century of public health progress in England and in this country the same heated contests have always been waged, as to the pace at which and the method by which the public health should be conserved. Tacit acceptance of principles has rarely if ever been paralleled with equally prompt initiation of action. The "How" and the "How Fast" of all public health procedures have always been the stumbling blocks in providing people with the full benefits of available scientific knowledge.

Since these two controlling brakes upon public and private activity characterize all advances in the public health field, it appeared profitable to your incoming President to evaluate the "friction" possibilities of these brakes in the various fields of public health activity during the next few years. How successful these devices for slowing up fruitful application of science have been during the past 100 years is probably already known to most of you. In July, 1938, the United States Govern-

* Presidential Address presented before the American Public Health Association at the Sixty-seventh Annual Meeting at Kansas City, Mo., October 23, 1938.

ment semi-officially and tentatively recognized and gave position to the ancient axiom that without health there is no wealth. Although the truism is approximately centuries old, its rediscovery in this country 100 years after its revival of recognition in England is important if it will carry us over "the ridge of the hill" to successful initiation of universal public health service. If, however, the rediscovery of an old and accepted principle is to lead to crimination and recrimination, to emphasis upon terminology, to confused battling about communism, local autonomy, dictatorships, local and central responsibility, and other important but not always relevant symbols of the times, then another century may pass before true and realistic acceptance of the principles of 1838 is to bear fruit.

Competent political scientists will no doubt point out that 100 years represent a short time in the evolution of technics of government. And if we use the historians' device of compressing the time scale perhaps a million fold, then it was only an hour ago that the Poor Law Commissioners emphasized the economic importance of disease and insisted that provision be made in the poor laws for the recognition of this fact. It was less than a second ago, too, that one of our most authoritative national associations gave official recognition to similar axiomatic principles.

To those impatient to provide the indigent and the middle class with adequate medical service and satisfactory hospitalization, and communities an opportunity to attain a reasonable level of public health service, the answer that the concept, without health there is no wealth, was recognized geologically only a few minutes ago, offers little solace and really no practical advantage. Philosophically we may believe that time will cure all evils, but in current operations "When" and "How" must become controlling issues for all of us.

THE FIELDS OF ACTION

It is generally agreed that the nation's health is in an unsatisfactory condition. It is probably further agreed that the primary causes of this unsatisfactory situation may be encompassed in something like the following four major defects:

1. The poor environment in which the great mass of the population is living and the inadequate control, even at this date, of the physical environment of the people
2. A relatively incomplete dietary
3. Defects in the organization of public health and medical services
4. Gaps in the knowledge of the causation and prevention of disease, and imperfect application of such knowledge as is available

The elimination or correction of the defects enumerated above by the sudden arrival of an economic millennium appeals to the imagination only at first thought. A keen observer of the American scene remarked at the National Health Conference in Washington, that "the fundamental needs of mankind are food, fuel, clothing, shelter, and a job, and medical care and dental care must always be subservient to those main human needs. Let us concern ourselves first with that question of food, fuel, clothing, shelter, and a job with adequate wages." He was stating only a half truth in the enthusiasm of the attack of the moment. No one doubts that the abolition of poverty and the complete institution of sanitary methods and immunization will still leave much ill health and disease with the rich and with the poor. Economic improvement is devoutly to be prayed for. It may be prophesied, however, that there will still be with us the malignant tumors, the appendicitises, the gastric ulcers, the chronic rheumatisms, the diseases of the cardiovascular system and of the kidneys, the diabetes, and others, which will continue to plague mankind, rich or poor, and will still demand public health and

hospital service and the family doctor in the future as at present.

Since the economic millennium is still around the corner and is not due for imminent arrival, much still remains for the public health officer and physician to do. Let us review briefly the fields of action which must confront the country during the next few years. In which of these should our maximum efforts be concentrated, and to which can this Association make its most valuable and prompt contribution?

ENVIRONMENT AND FOOD SUPPLY

Fortunately no one seriously controverts the desirability of maintaining and developing the environmental protective services directed toward general sanitation, pure water and food supply, good housing, and the control of infectious diseases. Great amounts of work remain to be done in the entire field of environmental sanitation. Millions of homes of inadequate character must be replaced. Little if anything has been done to deal with the evils of atmospheric smoke pollution. Noise increases while knowledge regarding its correction and its effects remains limited. Although thousands of bodies, official and private, exist for the control and distribution of supplies of water and the elimination of sewage, no national plan of comprehensive character has yet been completely formulated. In the field of industrial hygiene opportunities of incalculable extent lie untouched for the engineer, the physician, the nurse, and the chemist.

Man accepts the importance of these activities, however, because upon their successful accomplishment civilization rests. Argument may continue as to method and as to cost, but few if any are ready to eliminate or to fail to extend those services without which no modern community can survive. I give little time to it this evening, not because of its lesser importance, but because of

its universal and better recognition by both professional and layman.

Similar reflections may properly be made with respect to raising the level of food consumption and of improving dietary deficiencies of the population both young and old. Here, too, debate has moved from the realm of "How fast" to the "How," within the limits of existing scientific information. No acrimonious debate meets the proposal that children should be furnished with an adequate amount of properly balanced foods. The debate centers, rather, upon the procedure of obtaining the foods and of educating the public to their intelligent use.

DEFECTS IN THE ORGANIZATION OF THE PUBLIC HEALTH AND MEDICAL SERVICES

The key to the problem of the organization of public health and medical services lies in the simple fact that, "notwithstanding great advances in medicine and public health protection, the American people are not so healthy as they have a right to be." Statistical demonstration of this fact is by this time reasonably agreed upon. At least no important criticism of this particular phase has appeared on the public health horizon. Almost everybody agrees that millions of American people are suffering from disease and that probably over a hundred thousand of them die each year from preventable causes.

Some three years ago the late Edgar Sydenstricker summarized these facts perhaps more dramatically than has since been done. I am taking the liberty of referring in some detail to one of his last public addresses in 1935. He then said:

The ravages of typhoid fever, diphtheria, and smallpox have been enormously lessened; they ought to be and can be eradicated. The infant death rate has been cut in half in the last quarter century, but it can again be cut

in half. Mortality from tuberculosis has been reduced by 60 per cent since 1900, and could be halved again. Two-thirds of the annual thirteen thousand maternal deaths are unnecessary. At least three-fourths of a million cases of syphilis are clinically recognized annually, but more than half of these do not obtain treatment at that stage of the disease when the possibility of cure is greatest. We have been rather vociferous in recent years over the health and welfare of children; yet it is estimated that 300,000 are crippled, a million or more are tuberculous, and nearly half a million have heart damages or defects.

The mortality of adults of middle or older ages has not appreciably diminished. The expectation of length of life at forty is about the same now as it was in 1850, 1890, or 1900. The mortality of adults who should be in their physical prime—20–44 years of age—is almost as great as that of the younger group, which includes babies and children. The mortality of persons who ought to be in full mental vigor and still capable of many kinds of physical work is over three times that of the younger adults. In the young adult ages—20–34 years—tuberculosis still tops the list as a disease; accidents and homicides snuff out about one life in a thousand annually; organic heart disease appears in even this young age period as the third most important cause of death. All careful studies of illness and physical impairments corroborate these ghastly records; in fact, they reveal even more impressively than mortality statistics the extent to which the vitality of the population is damaged in the most efficient period of life. This disconcerting evidence of impaired efficiency among our adult population takes on a graver significance in view of the changing age of our adult population. We can no longer squander the vitality of our grown men and women. The task of health conservation in the future must be broadened to include adults as well as children.

This appalling indictment of the state of the health of the Union is unfortunately only part of the story. The findings of the Interdepartmental Committee of the United States Government extend this indictment in even more distressing terms. Only a few of the more important conclusions of this committee are here presented. They round out one of the most serious and comprehensive attacks on our national public health deficiencies which have

been made available in the history of this country. Their disclosures—still uncontroverted—show that even today, generations after Disraeli, the first statesman to demand it, public health has not yet been made the first concern of the State. If anything, it remains a tenth-rate power in the competition for position in the governmental sun. Some of these findings are listed briefly below:

a. Fifty million Americans are in families receiving less than \$1,000 income a year.

b. For the ten most deadly diseases, the death rate is almost twice as high among unskilled workers as among professional workers.

c. The gross sickness and mortality rates of the poor of our large cities are as high today as they were for the nation as a whole half a century ago.

d. No physicians' care is received in 28 per cent of seriously disabling illness among the belt of normally self-sustaining families just above the relief level.

e. In the case of disabling illness lasting a week or more, one person out of four receives no medical care whatever among 20 million people in the relief groups, or among the 20 million people above that level who can purchase it only at risk of curtailing food, clothing, shelter or other essentials of health and decency.

f. Over 40 per cent of the counties in the United States do not contain a registered general hospital to serve their total of 17 million people.

g. There are counties in the United States where for a 5 year period there were no maternal deaths; there are others where the maternal death rate is more than 200 for each 10,000 children born.

h. In 1936, nearly a quarter of a million women did not have the advantage of a physician's care at the time of delivery.

i. For the great majority of the million births attended each year in the home by a physician, there is no qualified nurse to aid in caring for mother and baby.

j. One-third of the 35 million children under 15 years of age in the United States belong in families able to pay but little for medical care.

k. Every year 70 million sick persons lose more than one billion days from work.

l. Workers in industry have a life expectancy approximately 8 years less than non-industrial workers.

m. For respiratory tuberculosis, the death rate among unskilled workers is seven times as high as for professional workers.

n. In twenty-seven iron and steel towns, the death rate from pneumonia is two-thirds greater than in the United States as a whole.

o. A million workers are exposed to the hazards of silicosis.

p. Health supervision is inadequate in most industrial plants employing 500 or less workers, yet these represent some 62 per cent of the working population.

q. On the average day of the year, there are 4 million or more persons who are temporarily or permanently disabled by illness—unable to work, attend school, or pursue their customary activities.

r. Among gainful workers, there are on the average probably 7 to 10 days of sickness disability—in the course of a year—but these disabilities range from a day, a month, a year, to a lifetime.

CONTROLLING PRINCIPLES AND PROGRAM

Since no one has seriously challenged the statements of need so far presented, we may profitably pass to the more important controlling principles of action which should result from the statements of need. Fortunately, within a few seconds, upon the basis of the Gargantuan calendar of geologic time, equally universal agreement has apparently been reached in the United States on the controlling principles of action. Even at the risk of minor error, these agreed principles are re-stated here in the briefest possible terms. They are:

1. The extension and modernization of public health services.

2. The strengthening of attack upon four great threats to life: tuberculosis, venereal diseases, malaria and certain occupational hazards.

3. The reduction of deaths from pneumonia and cancer.

4. The reduction of morbidity from mental disorders.

5. The expansion of maternal and child health services.

6. The expansion of general hospital facilities where need exists and the extension of the use of existing hospital facilities.

7. The recognition of the principle that

the complete medical care of the indigent is a responsibility of the community, medical and allied professions, and that such care should be organized by local governmental units, supported by tax funds and stimulated and coördinated by the federal government.

8. The provision of minimum medical services to 20 million additional people close to the emergency level.

9. The rôle of the federal government should be principally that of giving financial and technical aid to the states in their development of sound programs through procedures largely of their own choice.

10. The extension of the principle of hospital service insurance.

11. The development of voluntary or compulsory health insurance to meet the costs of emergency or prolonged illness.

12. The development of programs of insurance against loss of wages during sickness.

13. The further development of our public health and medical service should rest largely upon the members of the medical profession.

COST

The cost of accomplishing these objectives is in the neighborhood of \$850,000,000 annually. Today, the people of the United States expend approximately $3\frac{1}{4}$ billion dollars annually for health services. The individuals pay approximately 80 per cent of this cost direct, while government pays 16, philanthropy 2, and industry 2 per cent. The new program, therefore, based upon an agreed platform, need not entail additional expenditures by the people of the United States. They require, on the contrary, a more intelligent and logical completion, unification, and coördination of health and medical services upon a nation-wide base. These in turn will require new channels for old expenditures, with new objectives re-defined and strengthened by public, private, and voluntary action.

THE RÔLE OF THE A.P.H.A.

For the first time in our history, therefore, all forces have agreed upon an expansion of public health and medical activity, upon the principles which should control it, and upon the probable

costs involved. This general agreement, however, by no means eliminates the necessity for hard thinking. What we like to call the details of execution and of administration, in this sphere of action as in others, still remain the rocks upon which the program may founder.

Public health now enters seriously for the first time the field of competition with other governmental activities. We want it to become a "first rate power" whose aim, unlike that of some other "first rate powers," is to save rather than to destroy lives. If it succeeds it becomes at once a competitor of the ancient and powerful consumers of public and private funds—armaments, highways, flood control, navigation, general education, etc. What position should the advocates of public health expansion take in this competition for public funds? How should this field of endeavor be adequately integrated with other important and necessary spheres of governmental activity?

In the second place, what balance of power, both in initiation and in current administration, should be maintained between local and central government? What shall be the relationship of private medical practice to public health service? Rigid attention to the detail of safeguarding the quality not only of medical service but of general public health service, is essential if we are to avoid the crystallization into "accepted practice" of the less efficient methods of present practice or even an increase of the total amount of illness of real or imagined character.

The obvious economic risks attached to various forms of compulsory health insurance should not be lost sight of and certainly should be made the subject of rigid economic inquiry.

The sheer problem of integration of various public and private forces is one to give us all pause, but it should

be remembered that many of these problems assume immeasurable difficulties on paper, while their administration in fact goes on around us. One observer has already pointed out, for example, that if one were to list the necessary governmental and private activities essential for daily existence on Manhattan Island, he would be forced to conclude that such an organization of society is too complicated for successful accomplishment. The fact remains, however, that Manhattan Island lives successfully and regularly and with low death rates and other amenities which may well match or surpass those of the simplest village of 200 persons.

We should not permit our fears of difficult and complicated administrative action, therefore, to sap the courage necessary to embark upon a new program of advantage to the people of this country if the facts justify the desire. This road to new accomplishment may properly be travelled with the past fresh in mind, namely, that the methods of central governmental control may not always turn out to be the short and ready road to desirable reforms. But neither should these methods always be interpreted as leading directly and rapidly to the devil. The essential condition for effective local government lies in the force of local intelligence and will. In the creation of that force a wise and stimulating central government may play an important if not dominant rôle. No one discounts the difficult problem experienced by a Chadwick a hundred years ago of finding in local government politics the happy mean between the "too much" and the "too little" of central interference. While we are on that search it cannot be forgotten that the people must be served with the most intelligent use of the tools at hand. Offering a protest and nothing more may demonstrate a "liberal temperament," but a plan is essential to satisfy a people.

Your incoming President assumes that the American Public Health Association unites in a protest against inadequate service, agrees on a plan and will take a position promptly in crystallizing the details of that plan and in contributing its advice to the development of a structure permanently designed to supply the people of this country with reasonably adequate public health, medical and hospital service. To implement these purposes, the speaker tonight proposes that the Association undertake a series of duties which will demonstrate its faith in the plan and its desire to prove its workability. These proposals for action are:

1. That the Association adopt in principle the concept of public health responsibility set forth by Sydenstricker in the following terms:

"Society has a basic responsibility for assuring, to all of its members, healthful conditions of housing and living, a reasonable degree of economic security, proper facilities for curative and preventive medicine and adequate medical care—in fact, the control, so far as means are known to science, of all of the environmental factors that affect physical and mental well-being."

2. That the Executive Board appoint a committee of seven of the outstanding leaders of thought in the Association to cooperate during the coming year with the Inter-Departmental Committee of the United States Government, with the American Medical Association, and with the Conference of State and Territorial Health Officers, to study and agree upon a practicable plan for putting into effect without delay the major recommendations presented at the National Health Conference of 1938.

3. That the Executive Board develop in the immediate future,

- a. A re-statement of national health policy and of the objectives of the American Public Health Association in relation thereto.

- b. An evaluation of state and local health department organization in order to determine what future adjustments in major machinery of these institutions are essential to develop most efficiently the objectives of the National Health Policy.

- c. A plan for coordinating, unifying, and completing the agencies on a national level for the most satisfactory development of adequate health services.

- d. A study of guiding principles which should control the grant-in-aid procedure of the federal government, with particular reference to the long and varied experience of the central governments in England, Canada, Australia, and the United States.

- e. An authoritative statement on the various private and compulsory health insurance plans now available or in use which may serve as guides for experimentation in various areas of the United States.

- f. An evaluation of the relationship which public health activities should bear to other important public undertakings, such as welfare, education, and so on, so that a more reasonable balance of governmental activity may be maintained within the limits of appropriation of funds in the various areas of the country.

The Association for a great many years has made important contributions to the field of administrative practice. It has before it at this time perhaps the most important contribution which it has ever been called upon to make. It is one in which administrative standards and structures are the key stones to a successful future edifice of health administration. To this task, the Association should dedicate itself.

For many years, we have preached that "Public Health is Purchaseable." The public at last seems willing to buy it. The Association must adequately define the terms of the bill of sale so that a willing buyer, the American people, may taste more completely of the fruits of science in the promotion and maintenance of positive health.

The Health of the Nation*

THOMAS PARRAN, M.D., DR.P.H., F.A.P.H.A.

Surgeon General, U. S. Public Health Service, Washington, D. C.

IN discussing public health in the United States it is tempting to dwell upon past accomplishments. It is pleasant to point with pride to the lowest general mortality on record; to a further decline in the tuberculosis rate, now less than 50 per 100,000; to a continually lower infant mortality and a significant reduction in the mortality of women during childbirth, which is 15 per cent lower this year than last. Similar satisfaction could be taken in the low level of death rates from typhoid fever, diphtheria, and many other preventable causes. Such rates, however, are based upon past records and compared with death rates of earlier days. If medical science were static, past records would be a useful yardstick. Medical science, however, is not static. Almost every year additions are made to scientific knowledge which make it possible for us to do more than previously was possible in the prevention of disease. Many tools for better health are being forged in our scientific laboratories.

There is every reason why we should accomplish more now than in the past. Moreover, an awakening public sentiment and the increasing interest of doctors in disease prevention as well as cure, make it possible for us to do far more than has yet been done in putting medical science to work for all of the

people. Sickness and death rates of previous years, therefore, are inadequate yardsticks for the present and are utterly useless as goals for the future. Public health is a dynamic science. The horizon of knowledge is being extended year by year. Our plans for its application should embrace not only the knowledge we now have but should forecast the inevitable accretions to knowledge which year by year are making it possible to prevent deaths now considered inevitable.

The first large scale effort to shorten the lag between what we know and what we do, came in the provisions of the Social Security Act. Experience has shown that the basic plan of federal-state coöperation for health work was soundly conceived. In most states and communities it has been effectively administered. It has been possible to allot a ponderance of federal funds to those states and communities with the most meager financial resources but with the most urgent health problems. It has been possible to insist upon qualified public health personnel. The number of counties under the direction of whole-time health officers has been increased by 96 per cent. Federal funds have served to stimulate state and local appropriations. New funds from these sources exceed \$8,000,000. Vital services of state health departments have been strengthened. For the first time, a number of states have begun to provide for in-

* Read at a General Session of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

dustrial hygiene as a health activity. Emergency federal funds have provided sanitation, better water supplies, treatment of sewage, and malaria drainage. Greater progress has been made in public health during the past two years than in any similar period in our history.

One of the most important results of federal aid to health has been in the training of public health personnel. More than 3,000 health officers, nurses, laboratory directors, and other professional and technical personnel have been trained with Social Security funds.

During the past two years, also, we have seen two important additions to federal statutes relating to health. The National Cancer Institute was created by an Act of Congress last year and authorized to conduct studies relating to this disease; to promote coördination of similar studies conducted by other agencies; to procure and lend radium to research and treatment centers; to provide research fellowships and train cancer specialists; to coöperate with state health agencies in the prevention and control of cancer. The Act provides also for the useful application of research results with a view to developing the widespread use of most effective methods of prevention, diagnosis, and treatment of cancer. A building is under construction to house the Institute as a part of the National Institute of Health group, and an appropriation of \$400,000 is available this year for carrying out the purposes of the law.

For this fiscal year, funds are available to assist the campaign against venereal diseases. The Venereal Disease Control Act, passed May 24, 1938, authorizes coöperation of the states for the prevention and control of these diseases and studies by the Public Health Service to develop more effective methods. Appropriations authorized for the next fiscal year are \$5,000,000,

for the succeeding year \$7,000,000 and for the next ten years such amounts as the Congress may deem necessary to carry out the purposes of the Act.

Perhaps the most significant progress during the past two years, however, has not been in terms of legislation, nor yet in terms of actual public health accomplishment, but in the development and presentation to the country of a far-reaching national health program designed to deal in a comprehensive way with the whole problem of health and medical care.

Two years ago in "Reporting Progress" I discussed with you the health services made possible by the Social Security Act. Last year Assistant Secretary Roche in a historic address summarized the findings of the National Health Survey; documented the long known fact that the sick are poor and the poor are sick; added conclusive evidence that the poor receive the least and the least good medical care; argued convincingly that the treatment of the sick was no less a responsibility of health officers than the prevention of disease; and recommended that this Association appoint a committee to coöperate with appropriate federal agencies and the medical profession in working out national plans for the medical care of the underprivileged. Such a committee was appointed.

Three months ago under the chairmanship of Miss Roche and at the suggestion of the President, a National Health Conference was held in Washington. To that conference were presented the needs of the American people for health and medical care and definite proposals as to the several methods by which we as a nation can meet these needs.

The first recommendation was for the expansion of public health and maternal and child health services in order to minimize the risk of illness, to reduce

its current volume by expanding present federal-state coöperation under the Social Security Act. Through strengthened local health organizations it was proposed that a major attack be directed against those causes of disease and death for the control of which we have scientific weapons of unquestioned power.

To meet the great deficiencies in our physical facilities for good health it was recommended that additional hospitals, mental and general, tuberculosis sanatoria, health centers, and rural hospitals be built.

For the medically needy it was recommended that public medical care be provided for the dependent groups of the population, and for those who, although able to obtain food, shelter, and clothing from their own resources, are unable to procure necessary medical care.

To meet the economic burdens of unpredictable illness among self-supporting persons it was recommended that either general taxation, or special tax assessments, or specific insurance contributions, provide the funds. The rôle of the federal government in this respect should be properly that of giving financial and technical aid to the states in their development of sound programs of their own choice.

It was recommended also that insurance against the loss of wages during sickness be provided by an extension of existing unemployment provisions and other provisions of the Social Security Act.

It was urged that this program should be developed in an evolutionary manner over a period of ten years; that it should not be a federalized operation of health and medical care but that the federal government should use funds through grants-in-aid to assist in equalizing the financial burdens, to insure minimum standards and to give the incentive to all parts of the country

to join in a national movement. Finally, it was stated that if a more limited health program were contemplated, priority should be given to the first and second proposals.

The National Health Conference dissected the whole complicated problem of medical care into its component parts. It outlined clearly the next steps which we as a nation should take. Each of these steps is simple and understandable. It will require, however, the best professional thinking to fit all elements of the health program into a sound administrative scheme for the prevention and cure of disease; and to integrate this with our present activities at federal, state, and local levels. It is clear that we cannot continue to think in terms of the separateness of public, private, and voluntary efforts, or of the separateness of preventive and curative efforts to reduce death and disease. Each contributes to the health of the individual and the nation. All are parts of the same entity. They frequently are not smoothly functioning parts. Our job is to make them mesh.

There is every prospect that the next steps in a national health program will be taken soon. Each step will impose additional duties upon health departments in every state and community. Since there is general acceptance of the principle of unity between the prevention and treatment of disease, sound public policy dictates that there should be a unity of administration for health and medical care programs. The health department obviously is the one agency best fitted to do this job. A national health program will not be launched full grown as an emergency measure. It is deliberately planned as an evolutionary development, in some of its phases covering a ten year period. None of us knows exactly the rate of progress in developing each of its several parts. All are confident that the

basic objectives are sound. There is no serious disagreement as to method. In some sectors we must learn by careful doing in order to plan the succeeding steps efficiently.

All of these facts point to the need that the health departments in every state, city, and county prepare to assume the added responsibilities which inevitably will be theirs. This will mean the training of a larger and better health personnel skilled in the several special scientific disciplines represented in this Association. To do this job well public health must be made a career service in every state, county, and city. No effective health program can be built on the quicksands of partisan politics. Appointments must be made on merit; tenure in office must be based on accomplishment.

In support of a nation-wide program of health and medical care, there is much more public interest than anyone expected. There is much more medical interest than anybody knew existed. The majority of medical opinion in the country, as reported through the House of Delegates of the American Medical Association, is more liberal in its view of national health problems than some of their spokesmen had indicated. The top men in clinical medicine, as individuals and as represented through their special societies, always have been leaders in progressive thought. Both of these groups in their thinking seem to be a little ahead of us whose job it is to serve the public health.

Public health seems to be one of the most popular issues in the country, non-political in character, appealing to all shades of opinion. But we must remember that this popular support will be transitory and evanescent unless the health services in every community are efficiently conducted. The success of a national program will depend on how fully the needs of the people for public health and medical care are served.

From this point on, the attitude of lawmakers and of the public generally will be determined by what each state and local health officer does. It is on this basis that judgments will be made and progress will be possible. Even in advance of federal action there is a mass of public feeling at the health officer's command. It is his to be used for health improvement in any county or city where he is intelligent enough to organize it.

In an earlier time the pioneers of public health were alone in the wilderness. Few among the medical profession and the general public knew what health officers were doing or why. Our job is easier now. The doctors and the public are beginning to understand the social and economic importance of your job and mine. The health officer is no longer in the front rank of public opinion. In fact, he needs to think fast and to act effectively if he is not to lag behind.

Nor is the new attitude of the American people toward public health an isolated phenomenon. During the past summer I have been studying public health and medical problems in Central and South America. As chairman of the United States delegation, I attended the Tenth Pan American Sanitary Conference held in Bogota, Colombia, during the first half of September. Pursuant to treaty provisions, every American republic was represented by official delegates. From almost every country reports were presented which told of extraordinary activity in public health and in medical care for the underprivileged. These reports were verified as I visited several of the countries themselves and observed their activities. In tuberculosis and venereal disease control, in social security measures, in national programs for better nutrition, in maternity and child health work, no less than in the control of such pestilential diseases as

yellow fever and plague, great progress is being made, even in some nations otherwise backward.

Of great significance for the purposes of our present discussion is the fact that these measures are not being imposed by central governments upon apathetic populations, but are being carried out—in some cases reluctantly—because of widespread and insistent popular demand.

Public health has become a people's cause. The people have become insistent that they be given the benefits of what scientific knowledge has verified as valuable for the prevention and relief of disease and for the maintenance of healthful living. They are entirely willing to support, also, further studies to solve those problems of health and disease which still baffle us.

The Renaissance was the great upswing from the dark ages toward art, literature, and beauty in every form. It burst forth simultaneously in a hundred cities of Europe because the people were ready for it; it was the spirit of the age.

The French Revolution was the beginning of a world-wide fight for political freedom, in which our own young

nation played its gallant part. The world movement toward beauty of form and expression seems to have leveled out. The world movement for freedom is alive only in isolated nations. But I believe that today we see the first faint stirrings of a world movement for health—a people's fight for life, for freedom from disease, for an equal opportunity to be born well and to live well.

Science has shown the way. Not only by the fruits of its labor which has saved men's lives, saved them suffering, and maintained their physical and mental fitness, but also through the orderliness of mind, the clarity of vision, and the willingness to sacrifice for truth (which are the fundamentals of the scientific spirit), it is my firm belief that man may hope to raise himself high enough in the human scale to master his own machines and to affirm his own destiny, rather than become the passive instrument of self-designated supermen.

Science has shown the way. The scientists of public health must be prepared to meet the demands of leadership. To do so may be the greatest contribution to social peace in our day.

Present Status of Dental Caries in Relation to Nutrition*

NINA SIMMONDS, Sc.D.

University of California College of Dentistry, San Francisco, Calif.

THE rôle of nutrition in the cause and prevention of dental caries is perhaps one of the most controversial topics in dental research today. Only a brief discussion of the nutritional and bacteriological aspects of the problem can be given here. Reference is frequently made to papers already published and these should be consulted for further details.

Two recent papers present the dental viewpoints on the problem. Bödecker has discussed "Classification of the Lesions of Dental Caries and Factors Affecting the Rate of Penetration of Dental Caries,"¹ and Applebaum has reviewed "The various and variable factors which have been implicated in the mechanism of caries" under the following headings: (a) Bacteria and Enamel Decalcification, (b) Food Impaction, (c) Mechanical Injury, (d) Physiological Factors in Caries, (e) Proximal Enamel Caries, and (f) Caries in the Dentin.²

At least 4 avenues of approach to the problem of the prevention and arrest of dental caries have been suggested:

1. Prevention by Operative Procedures
2. Prevention by Proper Mastication
3. Prevention by Diet
4. Prevention by Mouth Hygiene (especially as regards certain species of bacteria among which is *L. acidophilus*)

The first two are strictly dental, so the opinions of dentists as to their relative merits will be of greatest value. The third, Prevention by Diet, will be discussed in connection with the fourth, Prevention by Mouth Hygiene. The use of the tooth brush in personal hygiene is an accepted practice so will not be considered further as a factor in reducing caries incidence.

The reason for discussing Prevention by Diet and Prevention by Mouth Hygiene together is that the data extant show that the foodstuffs comprising the diet determine in great measure the flora of the mouth. I question whether this correlation has been sufficiently emphasized in interpreting the rôle of nutrition in dental caries.

Although Boyd, Drain, and Nelson of the University of Iowa were by no means the first to associate nutrition with the prevention of tooth decay, the diet published by them in 1928 and 1929 tended to focus attention upon the Prevention by Diet viewpoint.³ The following foods plus insulin formed the basis of the daily menus of diabetic children in the University Hospital: 1 quart of milk, 1 egg, 1 serving of meat or fish, 1 orange or tomato, one additional fruit, 1 teaspoonful of cod liver oil, 6 teaspoonfuls of butter, one portion ($\frac{1}{2}$ cup) leafy vegetables (spinach, chard, greens, cabbage, etc.), one portion ($\frac{1}{2}$ cup) meaty vegetables (peas, beans, carrots, etc.).

After the children had been confined

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

to this diet for several weeks the observation was made that cavities in the teeth had not progressed further—tooth decay had been arrested. There is no need to detail the dietary properties of these foods; their importance in any diet (or foods containing the same dietary essentials) is too well known to warrant further comment.

For many years prior to the work of Boyd, Drain, and Nelson, Bunting and his coworkers at the University of Michigan had been interested in the dental health of children in certain orphanages in Michigan. For several years the diet of the children in one of these orphanages was admittedly below the standards accepted as normal for children as regards protein, calcium, phosphorus and vitamins, and yet during this time these children had a very low incidence of tooth decay.⁴

What is a possible explanation of this apparent paradox regarding diet and tooth decay? The facts are that two very dissimilar diets have been published, each claiming either to prevent or arrest dental caries—one obviously, adequate, and the other admittedly inadequate.

It should be stated that neither Dr. Bunting nor his coworkers ever said that this inadequate diet produced optimum growth and well-being in these children. In fact Koehne reported "that 40 per cent of the 201 children between the ages of 8 and 18 who lived in the institution for an average of 4 years were stunted in height according to the Woodbury standard."⁵

Apparently confusion arose over the following points of view which were not clearly defined:

1. Caries was arrested and prevented by a diet which stunted the growth of many of the children confined to it.

2. Caries was arrested and prevented by a diet which would induce good growth and well-being in children confined to it.

In other words, *prevention of caries*

by diet was confused with the *promotion or retardation of growth and well-being* by diet.

A comparison of the diet of the children in the orphanages with that fed by Boyd, Drain, and Nelson to the diabetic children shows that whereas the two diets vary greatly in nutritive value, especially as to minerals and vitamins, they are very much alike in one important detail—namely, they are both low in sweet foods such as jams, jellies, marmalades, cakes, cookies, candy, honey, sugar, and syrups.

The diets of diabetic children or adults contain varying amounts of carbohydrate, which comes largely from the 5 and 10 per cent fruits and vegetables with small amounts from cereals and bread and none or very little from the highly sweetened foods. The orphanage diet contained liberal amounts of cereals (starch) but in reference to sugar and other sweet foods, Dr. Jay, a coworker of Dr. Bunting, states: "Candy was strictly forbidden in the institution, sugar was never served at the table, and artificially sweetened desserts were served only on special occasions."⁶

This one detail, namely very low intake of sweet foods in both regimens, undoubtedly accounts in part at least for the observed results, low incidence of tooth decay. An appreciation of the one point of similarity in these two dissimilar diets is unquestionably a step in advance in our understanding of the problem of the rôle that sweet foods play in nutrition and the development of dental caries.⁷ In some instances apparently starchy foods may also be an etiological factor in caries. In recording data, it would be better to use the terms starches, and sugars, or to name the suspected foods, rather than to use the general term carbohydrates.

Sweet foods have been accused of causing tooth decay for many centuries. According to Pickerill, Aristotle who

lived from 384 to 322 B.C. said in his book entitled "Problems": "Why do figs when they are soft and sweet produce damage to the teeth? Perhaps the viscous softness of the fig causes small particles to adhere to the gums and insinuate themselves into the dental interstices where they very easily become the cause of putrefactive processes."⁸ If the term putrefactive were changed to fermentative the statement would sound very modern. Weinberger quotes the following from *A Treatise on the Teeth*, by A. Tolver, published in 1752: "All kinds of sweetmeats and sugar contribute very much to the destruction of the teeth, because their gluey juices stick to the teeth; besides, sugars are of an acid, penetrant and corrosive nature. Those who love sugar and use it much, rarely have good teeth."⁹ Numerous other references associating sweet foods with dental caries could be cited but these two will suffice to show that the correlation did not begin in the 20th century.

Because of numerous observations that persons who chewed liberal amounts of sugar cane on plantations did not have rampant decay, the rôle of sweets in tooth decay was seriously questioned by dentists about 1912.¹⁰ The following sentence is quoted from the book by Dr. J. Sim Wallace of England: "An explanation of the fact that the teeth of children who chewed sugar cane were relatively free from caries may be that sugar cane is a highly fibrous foodstuff and detergent in its effects, while the sticky sweets consumed by civilized man are not detergent and therefore induce caries." According to Bogert it takes 3 feet of sugar cane to make one standardized cube of sugar, hence one would have to chew a great deal of cane before very much sugar would be ingested.¹¹ In the light of Dr. Bödecker's studies the vigorous chewing of sugar cane would not only have a cleansing action on the

teeth but also would increase the flow of blood to the dental pulps which in turn would improve the quality of the dental lymph and thus increase the resistance of the tooth to decay.¹² Workers on plantations would also receive vitamin D from sunshine which in turn may be a factor in lessening the caries incidence.

Only when the semi-solid medium was developed so that bacteria could be separated into species was it possible to formulate a working hypothesis as to the etiology of dental caries. In 1890 Dr. W. D. Miller as a result of his work in Dr. Robert Koch's laboratory formulated his now famous theory of tooth decay, as follows: Mouth organisms produce lactic acid in fermenting carbohydrates, and lactic acid decalcifies tooth enamel. Miller also noted that decalcification of enamel occurs at "retention centers," pits and fissures and proximal surfaces.

Dr. F. W. Broderick of England in *The Principles of Dental Medicine*, states "Miller's theory cannot be considered as fully explaining the various circumstances in which we find the presence or absence of caries. Although the theory may be true as far as it goes, and I personally have little doubt of its truth, it cannot be, by any means, the whole truth. It leaves too many questions unanswered, too many undoubted clinical facts unexplained."¹³ This probably expresses the opinion of the leaders in the dental profession today.

There are two schools of thought regarding the bacteriological problems involved in dental caries; one represented by Drs. Bunting and Jay at the University of Michigan, and the other by Drs. Hatton, Fosdick, and Hansen at Northwestern University. Although these investigators differ as to the organisms involved they are in agreement that a diet containing liberal amounts of sweet foods is as a rule more conducive

to tooth decay than a diet low in sweet foods.¹⁴

I shall not undertake a detailed discussion of the dietary studies on prevention of dental caries made on children under 15 years of age by McBeath,¹⁵ by Tisdall and coworkers,¹⁶ or by Mrs. Mellanby,¹⁷ to mention only a few investigators. These workers have in the main stressed the importance of vitamin D in caries prevention. However, the diets which they have fed to children, with the possible exception of those used by Mrs. Mellanby, have been low in sweet foods. It is impossible for me to evaluate her data until more details are given.

Is it not only fair to those investigators who are interested in the bacteriological aspects of the problem to ask the following questions: Is it vitamin D which has arrested caries or have these children been fed diets low in sweet foods which would produce a low count of *L. acidophilus* and/or other organisms concerned with acid production in the mouth and hence the conditions necessary for tooth decay have not been present? Is not Dr. Jay correct when he states . . . "in part, at least the beneficial effects of a satisfactory diet have been due to the automatic lowering of sweet food"?⁸

Before commenting further on the studies of McBeath and Zucker I quote some comments on dietary studies in general made by Dr. Mary Moore of Philadelphia:

My own experience makes me question the assumption that little or no caries before 14 years of age assures little or no caries after this age. My report covers 80 cases seen on an average of three or four times a year continuously over a period of 15 years, from the age of 6 to 21. The individuals from whose records I made this report have had not only uniformity of dental diagnosis and treatment but also the benefit of medical care and good food . . . I question the claims that control or prevention of decay can be affected by diet, hygiene, and medical and dental care, unless many years have proven

the validity of such claims. Eight years' observation would have shown, at any time, over 50 per cent of the group free from decay. Yet, observation for 7 years more shows that a belief that decay had been controlled would have been an illusion.¹⁸

Although Dr. Moore reported on only 80 cases, her points are well taken. Most of the caries prevention studies have been made on children under 15 years of age and the periods of observation have been short compared to the length of time she has followed her cases. Investigations have not included children during adolescent years when caries is so often rampant. Hogeboom has discussed the etiology of caries during these teen years from the standpoints of endocrinology and nutrition but has left the question open due to insufficient data.¹⁹

There are two points of view on the rôle played by foods in the dental caries problem:

1. Sweet foods lodge in secluded areas, are acted upon by bacteria which produce acids which attack the enamel.
2. Liberal eating of sweet foods inhibits consumption of other foods which contain dietary essentials such as calcium, phosphorus, fats, proteins and vitamins.

Dr. Applebaum states: "Enamel decalcification is the first essential lesion of dental caries."¹ This supports the first point of view which may be expressed as follows: the flora of the mouth as modified by diet plays a rôle in tooth decay.

So far as I know there are no data extant which directly support the second viewpoint.

Although in the last analysis it is perhaps unfair to stress the importance of any one factor in caries prevention because the body functions as a whole, the paper by McBeath and Zucker, June, 1938, "The Rôle of Vitamin D in the Control of Dental Caries in Children" is of special interest in connection with the second viewpoint expressed above. They make the follow-

ing statements which appear to focus more attention on the importance of vitamin D in caries prevention than any data reported with which I am familiar. They state:

At School A, a new type of experiment was introduced, namely the feeding of the Boyd and Drain diet without the addition of cod liver oil. This resulted in a distinct but moderate reduction of caries incidence which by no means reached the low levels recorded when cod liver oil was included.²⁰

This observation is of tremendous importance from the practical standpoint of controlling caries by diet for the following reason: If the menus served at School A were identical with those served in the other institutions where studies were being conducted and the only variable was that the children at School A were not given the cod liver oil whereas the other children were given it daily, what other explanation is there except that cod liver oil (vitamin D) permits a higher intake of starches and sugars than is possible without it?

No one could say that omitting 3 teaspoonfuls of cod liver oil deprived the children of any known dietary elements except vitamins A and D and small amounts of fat and iodine. The original Boyd and Drain diet contains an abundance of these, hence in the McBeath and Zucker experiment vitamin D is the only factor left to consider. If vitamin D does permit a higher intake of sugar and starches, what is the explanation? Due to the rôle of this factor in calcium and phosphorus metabolism, are the teeth better nourished through the dental lymph when the diet includes a liberal amount of vitamin D? Are they thereby more resistant to the action of acids produced by the flora of the mouth and hence do they show less tooth decay?

These investigators do not comment upon the sunshine which these children

received. If the schools were all in one locality this point is probably of little importance. But in all research where human beings are involved this sunshine variable must be recognized, otherwise confusion may result in interpreting nutrition studies in various parts of the country. The sunshine in Santa Fe, N. M., is unquestionably of greater value than that available to children in a large smoky northern industrial city.

There are two points upon which all investigators would unquestionably agree:

1. A highly satisfactory diet not only for expectant and nursing mothers and young children but for all persons at all ages is a major factor in attaining the goal of preventive dentistry, preventive medicine, and nutrition. Such a diet is of importance not only from the standpoint of general health, but also from the standpoint of making the best teeth possible in the face of personal idiosyncrasies. It is probable that diet plays its greatest rôle in building good teeth during the first 10 years of life. According to Cockayne, hereditary dental defects manifest themselves as other physiological defects do; so an optimum diet is not a panacea for all dental problems.²¹

2. When it is known why certain persons are less susceptible to dental caries than others, and this appears to be the case, science may have a clue to the fundamental principles underlying the cause of this disease.

The question may be asked "Of what value to the practising dentist and to those interested in dentistry from the public health point of view is knowledge of our present understanding of the relation of diet to the flora of the mouth, which in turn apparently means the presence or absence of tooth decay?" It should be mentioned that observations on primitive races and also on numerous persons living under civilized conditions have shown that lack of mouth cleanliness may not and often does not bring about tooth decay when the intake of sweet foods is low. It is the change in the flora due to the intake of sweet foods (starches may also be involved at times) which plays a rôle

in caries incidence according to certain investigators.^{4, 14}

Dr. Bunting says "No tooth was ever made that was strong enough to withstand the forces of caries if they were active in the mouth" and "The hope of controlling dental caries through dietary regulations by building teeth strong enough to withstand caries is wholly unwarranted."²²

Undoubtedly what Dr. Bunting intends to say is that ruling out the small percentage of the population which for no known reason seems to be caries resistant (immune), it is impossible for the majority of persons to build teeth strong enough to permit a high intake of sweet foods. This point would appear to be well taken because no one has reported prevention of dental caries on a highly satisfactory diet which contained a liberal amount of sweet foods.

The data on the relation of nutrition to dental caries may be summarized into the two following practical suggestions:

1. If an individual is susceptible to tooth decay, he should reduce his intake of all sweet foods to a minimum. In this way he will keep the flora of his mouth low in those organisms known to be acid formers. Starches and fats should be his main energy foods.

2. In addition to keeping the intake of sweet foods low, each person should plan his diet so that all factors, including vitamin D, are present in abundance.

The disadvantage of these suggestions is that no one can do these two tasks for us. Each individual must accept the responsibility for taking a highly satisfactory diet and also for lowering his own intake of sweets. Parents must assume the responsibility for children.

Because of this individual responsibility from which at the present time there appears to be no escape, the problem of lowering the incidence of tooth decay is far more difficult to solve than if it were possible to attack it as some other problems in public health are handled, for example, vaccination against smallpox. Whether Dr. P. R.

Howe's Ammoniacal Silver Nitrate Solution as recommended by Dr. J. M. Prime of Omaha will be the method for control of dental caries from the public health standpoint remains to be seen.²³

Long experience in studying dietary problems makes me question whether entire freedom from dental caries, even if this were possible, would be sufficient to induce the average person to refrain entirely from sweet foods. It is perhaps a sounder policy to urge moderation in rather than abstinence from sweets, and admit that some tooth decay will probably result in most instances even though the individual has the best possible personal and professional mouth hygiene care. Optimum nutrition in the light of Dr. Bödecker's work may permit a little more leeway on sweets than a less satisfactory diet.

The cause of dental caries is an exceedingly complex problem but the data extant would appear to force the recognition of the relation of sweet foods to this disease. Again science has apparently offered a theory which seems to explain human experience. The science of nutrition contains numerous comparable examples—the rôle of diet in beriberi, scurvy, pellagra, and xerophthalmia; the rôle of cod liver oil and sunshine in rickets. Continued research on dental caries will unquestionably bring about as satisfactory an understanding of the many factors in this disease as it has in the case of the nutritional deficiency diseases.

Development of Industrial Hygiene in the United States*

J. J. BLOOMFIELD, F.A.P.H.A.

Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

STUDENTS of industrial hygiene have known for some time that the health of the worker may be influenced not only by the working environment, but by factors associated with conditions outside the factory. However, it is only within the past year or two that we are beginning to realize that industrial health forms an integral part of the health of the community, and that our approach to industrial hygiene should be from the public health viewpoint. In view of the tremendous interest in industrial hygiene and the attendant rapid growth in industrial hygiene activities which has been taking place in this country during the past three years, it is most fitting and timely that we take inventory of the entire industrial health problem, its development, progress and future.

THE INDUSTRIAL HYGIENE PROBLEM

To assist us in determining the needs and the type of action to be taken in this field of public health, it is essential to consider first some aspects of the magnitude of the problem.

If we look upon industrial hygiene as adult public health, it is obvious that we are concerned with a large percentage of our population since, accord-

ing to the last federal census, there were approximately 49 million gainfully employed persons. In the past, industrial hygienists have concentrated their efforts on the so-called *industrial population*—that group of workers engaged in the manufacturing, mechanical, and mining industries. Although it is probably true that the bulk of the occupational diseases occur in these industries, nevertheless, the 10 million workers in agriculture, the 4 million persons employed in transportation and communication, and the large number of workers in domestic and personal services, all have health problems deserving of attention.

While insufficient data have thus far prevented our recognition of the health problems in non-industrial pursuits, we have ample evidence to indicate that there exists a greater mortality rate in the industrial population than in the whole group of gainfully employed persons. Excess mortality is especially notable among unskilled workers, among whom the death rate from all causes in certain states was found to be 100 per cent in excess of the death rate among agricultural workers.

Studies of illness in industry made by the U. S. Public Health Service also show high rates of illness among workers. For example, the incidence of degenerative conditions and such diseases as occupational tuberculosis, and

* Chairman's Address presented before the Industrial Hygiene Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

pneumonia was found in the industrial population to be higher than average. There is evidence to justify the opinion of authorities in the field of tuberculosis that deaths from this disease can be reduced 50 per cent by health supervision of workers in occupations predisposing to the disease, by detection of minimal cases, and by provision of adequate medical and institutional care in the early stages of the disease. A large amount of information testifies that a majority of cases are discovered too late for effective treatment. Again, it is also known that pneumonia mortality and disability are excessive among workers exposed to extremes in temperature, inclement weather, toxic gases, and dusts. Health supervision of the worker and his environment has been found effective in reducing illness and death due to this cause.

Workers employed in large establishments are provided health services to some extent. However, the provision of health services is made somewhat more difficult because of the fact that a large number of our workers are employed in small establishments. Recent studies¹ have indicated that as a general rule the smaller the plant the more costly is such a service to both the employer and the employee. In a study recently published by the American College of Surgeons on 299 companies employing 1,237,755 workers, it was found that establishments having 1,000 or more employees showed a per capita cost for medical and compensation purposes of \$8.42 as compared with a cost of \$13.52 for the plants having less than 500 workers. The significance of this finding becomes more obvious when it is realized that approximately 62 per cent of the workers in manufacturing establishments in this country are employed in plants having less than 500 workers. However, the obstacles associated with the development of a complete health service for employees

in these small plants may be overcome. But to do so will require increased activity and the coöperation of all agencies interested in health conservation. Public health workers can play an important rôle in correlating the activities of these agencies.

In considering the improvement of the health of our workers, we find that we are confronted with several problems. First, because the relationship between cause and effect is more evident, the disability and lost time due to occupational accidents is still very important. In spite of the fact that great strides have been made during the past 20 years in the prevention of accidents, this form of injury still constitutes an important problem. According to the last preliminary report of the National Safety Council, there were 19,000 occupational deaths in 1937.² Studies also indicate that we have not approached minimum rates since the records for accidents in certain steel companies with best practices show a far lower rate than for the industry as a whole.³ Second, it is well known that certain occupations are associated with poisoning, disease and high mortality. In the third place, many of our workers in early adult and late life are found to lack the physical capacity and mental stamina to undertake certain types of work. And lastly, we have come to realize that we have far too much absence from work due to sickness or fatigue, or other incapacitation due to a complex set of factors, some of which are no doubt controllable.

While accidents, occupational diseases, and high occupational death rates appear to be impressive, there is no doubt that the least dramatic side is probably by far the most important—namely, the lost time and incapacity due to illness. It is this last condition that is so widely prevalent as to be almost universal in all localities, at all ages, in all occupations. A vast amount

of wasted energy and life due chiefly to preventable illnesses, some of which may be contributed by the working environment, presents a problem in need of our serious attention.

Although we have made significant progress in the control of certain preventable diseases, as is evidenced by the declining trend of our death rate in the last 40 years, it is a fact that this saving of life has taken place chiefly in childhood and in early adult life. No significant increase appeared to occur during this period in the average years of life remaining to persons of middle and advanced age. The death rates from some important diseases of adult life have been increasing, a phenomenon understandable in the light of the fact that the principal causes of death operating in the advanced years are primarily chronic. Preliminary data from the National Health Survey,⁴ based on surveyed persons of all ages, show that chronic diseases, including permanent impairments, alone account for 6 of the 10 days of incapacity due to illness and accidents experienced by the average person per year; and with respect to sickness and accidents, data recently published by the U. S. Public Health Service show in the instance of a public utility that on the average 7.5 days were lost annually by males and 10.9 by females.⁵

These studies further show that approximately half of the deaths from chronic diseases occur in the working ages (15-64), and that about 87 per cent of the persons in this age group are reported to have such ailments. Furthermore, about 50 per cent of those reported with chronic disease fall into the groups under 45 years of age. All of these facts should focus our attention on the problem of chronic disease among younger workers, and it would seem that if an attempt were made to discover these diseases in their earlier

stages, a great saving in life and health would be accomplished. In other words, the greatest opportunity today for a substantial saving of life appears to be in the field of chronic diseases and the class offering this opportunity is the industrial population.

DEVELOPMENTS IN INDUSTRIAL HYGIENE

If we examine the early history of industrial medicine, we will find that the chief function of industrial medical departments was the treatment of traumatic injuries. Gradually, the work of the medical department began to extend beyond surgical treatment to the medical phases of the problem. Such functions as preemployment and periodic physical examinations, job placement, and, more recently, medical and engineering control of occupational diseases, began to take their rightful place in industry. Where in the past attention was given mainly to the improvement of machinery, recent activities have been directed to the economic waste resulting from failure to provide protection against controllable health hazards. One of the primary stimuli to the introduction of more adequate medical services in industry has been the passage of workmen's compensation laws for accidents and occupational diseases. Today, 46 states have laws providing benefits in the event of accidental injury, and 21 of these states have enacted legislation compensating workers for one or more occupational diseases.

With reference to activities outside of industry itself, we find that these were limited chiefly to research on the part of federal agencies and one or two universities. Although the research work conducted by such agencies as the U. S. Public Health Service, the U. S. Bureau of Mines, and one or two universities was productive of considerable knowledge concerning industrial health.

TABLE I

*Summary of Industrial Hygiene Activities in the United States**

State	Number of Gainful Workers	Number of Workers in Manufacturing, Mechanical and Mineral Industries	Number and Kind of Personnel				Annual Budget
			Medical	Engineering	Other Technical	Clerical	
Alabama	1,026,320	220,378	1	0	0	0	5,600

* All units in Health Departments except New York and Massachusetts; these two are in Labor Departments.

† Survey being conducted to determine state's needs in industrial hygiene.

hazards, very little application of these findings was in practice in the states. As a matter of fact, prior to 1936, industrial hygiene administration in state and local government was confined to three or four health departments, and one or two state departments of labor. In all probability, this limited work in

industrial hygiene also accounted for the few schools giving instruction in this field of public health.

Responsibility for safeguarding the health of our workers rests chiefly with state and local government. This fact is an outgrowth of our political system which gives much autonomy to

FIGURE I

the individual states. The agencies of the federal government concerned with industrial hygiene are engaged primarily in the collection and dissemination of information, conducting field studies, laboratory research, and protection of the health of federal employees. Prior to 1936 most states dealt chiefly with matters of safety, sanitation, employment of women and children, and compensation of employees following accidents.

When funds were made available by the Social Security Act for the development and extension of all branches of public health work, the U. S. Public Health Service, in cooperation with the Conference of State and Provincial Health Authorities of North America, inaugurated a program designed for the purpose of establishing active industrial hygiene work in state and local health departments. Table I presents a summary of industrial hygiene activities in the various states, while Figure I depicts graphically the progress of these

activities in the United States. It is evident that in the short period elapsing since the passage of the Social Security Act, the development of industrial hygiene has been rapid; and if our progress continues at the same pace, it may in time attain a level commensurate with its value to the national economy. It may be seen from Table I that there are now 26 industrial hygiene units actively engaged in this work, while 6 other states are conducting surveys for the purpose of determining their needs with reference to such a program. Where less than three years ago the small sum of approximately \$100,000 was being budgeted for this activity, today nearly three-quarters of a million dollars are being expended in this work. Where three years ago only 12 million gainfully employed persons were receiving a limited degree of industrial hygiene service, today approximately 40 million workers are given some consideration with reference to industrial health hazards.

The progress indicated appears phenomenal. But if we compare the 15 mills per worker being expended on industrial hygiene activities to the amount of money per capita spent for other public health work, and bear in mind the large working population in this country, the numerous problems still unsolved, the fact that we are spending billions of dollars annually in compensation and other costs for injuries and illnesses, it is apparent that we are still only at the beginning.

In inaugurating industrial hygiene programs the various states have been confining their efforts chiefly to the evaluation and control of occupational diseases in industry. This method of approach to the industrial health problem is logical for several reasons. First, the relationship between specific occupational diseases and environment is often evident, and tangible benefits of control practice are readily demonstrable. Second, the manner in which some occupational diseases have developed in certain industries has been of such a dramatic nature that the public has become more conscious of the importance of such diseases and the need for providing measures for their control. And finally, we must not lose sight of the fact that even today many public health workers view industrial hygiene as merely accident and occupational disease control. As already stated, however, industrial hygiene is essentially adult health promotion among the gainfully employed, and necessarily runs the entire gamut of public health for these individuals.

Nation-wide data to support this view are being collected and analyzed. It is hoped to have some basic statistics on the subject of illness and death by occupation in this country as soon as the U. S. Public Health Service has had an opportunity to analyze the results of its recent inquiry on more than a half-million workers. Limited statistics for

the prevalence of occupational diseases are available for only a few states, since the principle of compensating for an occupational disease is of recent origin in this country, and the general reporting of occupational diseases continues to be in a chaotic state. In Wisconsin a workmen's compensation law has been in operation longer than in any other state. Some unpublished analyses of recent data from this state have been furnished by Dr. W. M. Gafafer of the U. S. Public Health Service and bear examination. For the 16 year period from 1920 to 1935, occupational diseases accounted for 2 per cent of the total compensated cases. During 1935 this percentage increased to 2.8. During the same 16 year period, 2.8 per cent of the total costs for all injuries was due to occupational diseases, but during 1935 the corresponding percentage increased to 7.1. The compensation cases settled in 1935 represented a loss of over 2 million working days, and of these days lost, 8 per cent were accounted for by occupational diseases.

It is realized, of course, that some occupational diseases are not reportable, and a certain number of such diseases receive no compensation. Still, there is sufficient evidence to indicate that although the incidence of occupational diseases and costs are rising, they still constitute but a small percentage of total compensated cases and costs. Reports from other states, such as New York, New Jersey and Ohio, show a similar trend. According to the United States Department of Labor, the total direct and indirect costs of industrial injuries in this country are approximately 5 billion dollars annually, and of this amount, occupational diseases account for but a small percentage.

A valuable criterion in the study of disease is the amount of time lost from work. This test not only measures disability, but also reveals the social and economic significance of the problem.

Recent studies of absenteeism from illness and injury indicate that illness causes far more absenteeism than do industrial injuries. In a limited study made by the American College of Surgeons,¹ 116 companies in various parts of the United States, employing 352,591 workers, reported a loss of 208,648 days in 1936 on account of industrial injuries, or a loss of 0.6 day per person. Of this total amount of absenteeism for industrial injuries, occupational diseases accounted for only 0.01 day per person per year. Some of these reports to the American College of Surgeons contained accurate data on absenteeism, which showed that the average worker loses nearly 9 days per year from non-industrial injury and illness, or approximately 15 times as much time as he does from industrial injuries. Additional evidence on this subject has been reported recently in Great Britain,⁶ where among 5,197,643 persons employed in factories in 1935, there were only 428 cases of occupational disease, 163 of these being lead poisoning and 142 epitheliomatous ulcerations. Thus, the British experience with reference to occupational diseases appears to be similar to our own.

All of these facts indicate that the economic losses from absenteeism due to illness among industrial workers must be enormous. When we take into account the wide difference between the few millions of dollars spent on industrial hygiene by industry and government, and the billions lost due to accidents, occupational diseases and sickness in industry, we are forcefully brought face to face with the meager efforts of our present attempts in the direction of the protection and improvement of the health of our workers.

It would seem, therefore, that if we are to improve the general health status of the most important and numerous group in our population, it will be necessary to control not only unhealthful con-

ditions in the working environment, but also to give consideration to such factors as proper living conditions, nutrition, elimination of strain and hurry, communicable diseases—in fact, a general adult health program for our workers. In order to promote a broad and effective industrial health program of this type, it will be necessary to integrate it closely with existing public health activities.

AN INDUSTRIAL HYGIENE PROGRAM

Experience has shown that in the practice of industrial hygiene the essential features of a program should include fundamental research, application of research and educational activities designed to acquaint the public with the importance and needs of industrial health. State and local health departments are by the very nature of their organization and their responsibility most fitted to carry out the application and education phases of the program, leaving the investigative phases to federal, university, and other research agencies. In view of the experience of the U. S. Public Health Service in this field, it has been possible to recommend a program which could be undertaken by the various units.⁷

The determination of the scope and nature of the industrial hygiene problem should be the first consideration, and this will indicate the kind, magnitude, and direction of the work to be undertaken. It would be possible to make this determination in any state, were reliable statistics available on industrial morbidity and mortality, and accurate information on occupational diseases and accidents. At present such data are lacking in nearly all of the States; in some instances information on accidents exists, and less frequently, on occupational diseases. A preliminary survey of all work places, such as is now in progress in many of our states, will yield information on the potential occu-

pational disease hazards and on the extent of health services. However, the information obtained by such surveys is very limited, and steps should be taken to secure reliable data on lost time due to occupational diseases and other illnesses.

However, the preliminary surveys now in progress indicate that already sickness records are kept on nearly half of our working population. It is felt that by an intensive educational campaign among industrial officials and local physicians, arrangements can be effected for securing reports of absenteeism due to occupational diseases and other illnesses. These reports should be uniform and should be transmitted to the state department of health. Duplicate copies of selected data could also be furnished to the U. S. Public Health Service for study. The Service has been receiving such data for many years from a group of 30 industrial sick benefit organizations providing sickness benefits for approximately 170,000 industrial workers, so that the machinery for expanding this plan on a nation-wide basis has already been tried and found satisfactory. Such fundamental information will form the basis of constructive programs within the states, since it will then be possible to evaluate those conditions causing excessive absence due to illness and to take the necessary steps for their control. In so far as the federal government is concerned, data of this nature should serve as a guide in any future research in this field.

When the various health hazards in industry have been established, the industrial hygiene unit is in a position to evaluate each one and to determine the means necessary for its control.

It is evident from a study of the program recommended herein that the object has not been to carry on work which has already been done or which is being accomplished by other agencies,

but to supplement these activities with work which is necessary in order that public health may be brought to our industrial workers. For this reason, the Public Health Service has recommended that the industrial hygiene program be accomplished coöperatively and the local industrial hygiene units, in addition to furnishing services to physicians, industry, and labor, should serve also as a source of information for other state agencies. Perhaps one of the difficult problems which each unit has had to solve is that of coördinating its work with existing agencies, such as departments of labor, industrial commissions, and others.

The above program is a summary of the activities being attempted by the various industrial hygiene units in this country. As may be seen from an examination of Table I, most of these units employ a very small personnel—usually a physician, an engineer, a chemist and a secretary—and, in addition, are endeavoring to carry on this program with very limited funds.

It should be evident that if all the factors influencing the health of our workers are to be considered, then it will be necessary to draft all of the resources at the disposal of a department of health. This is a perfectly legitimate view of the problem if we pause to consider the method of approach which may be employed. For example, it is conceded that many of the diseases of childhood are not directly associated with the school environment; yet this fact has not deterred our health departments and practising physicians from doing their most effective work in the prevention of childhood diseases through the medium of the school. It is our feeling that the protection of the health of the industrial worker requires the same type of organized effort that has proved satisfactory for the protection of the health of the general public. Hence, it is logical to attempt to com-

bat our adult diseases by approaching the problem through the medium of the factory. For example, some public health administrators may feel that with the limited number of so-called industrial workers in their states, industrial hygiene activities may not be justified. Yet, there is no reason why these same health departments cannot carry on a program of nutrition, venereal disease, tuberculosis, or malaria control through the industrial groups in coöperation with the industrial hygiene unit. By so doing they will be practicing effectively public health among a vast number of people. At present such programs employ the home as a means of contact. It would seem that this approach of bringing public health to the factory should commend itself from the viewpoint of efficiency alone. The fact that many illnesses among our gainfully employed may not be directly caused by the working environment should not deter physicians and public health workers from attempting to eliminate the causes of these diseases through the working environment.

It is desired to stress the fact that in order to carry on any kind of public health work in the factory, it is still necessary that the personnel know industry and industrial processes, and for this reason the only persons logically to guide the work should be those particularly trained in the field of industrial hygiene. However, there is no reason why there should not be a closer coöperation between the industrial hygiene personnel in a state health department, the various local public health units, and the medical practitioner, in an attempt to bring public health to our gainfully employed and indirectly to their families.

In other words, the industrial hygiene unit in the state department of health will determine the nature and extent of the health problems in industry, will attempt to study and control those spe-

cific environmental health hazards which require highly specialized personnel, and will also integrate, as far as is practicable, with local health units, those public health functions which are for the common benefit of the industrial and general populations of the state.

I have attempted to picture the problem of industrial hygiene in this country, indicating its magnitude, its development, and have suggested a course for the future. Rather than essay to summarize my remarks, I should like to emphasize two points in my discussion which I consider of significance. First, we must supplement our present information on occupational diseases and accidents with a knowledge of absenteeism with respect to frequency, duration, and cause in each numerically important occupational group in a working establishment. Such data will serve to reveal to the management and to the public health worker the type of action which should be taken to obtain the maximum reduction in the amount of time lost from work on account of disability. We cannot brush aside the fact that it is this lost time which is so important both from a humanitarian and economic viewpoint. Second, we must consider the industrial hygiene problem as one of adult health. It seems to me that only by approaching the subject of industrial hygiene from the standpoint of adult hygiene will we be able to make the necessary progress in this important field of public health.

To accomplish this effectively, it will be necessary first to develop a strong industrial hygiene unit in the state health department, consisting of various specialists in the field of occupational diseases and other causes of disability. With such a unit to guide the work, it should be possible to integrate existing public health activities with the program of industrial hygiene. Only by such co-ordinated effort can we hope to improve the health of our industrial workers.

Value of the Vital Statistics Data on Birth and Death Certificates in County Health Work*

EARLE G. BROWN, M.D., F.A.P.H.A.

Commissioner, Nassau County Department of Health, Mineola, N. Y.

VITAL statistics are of tremendous value to every health department—local, state, or national. From these data it is possible to learn the number of individuals born each year, the number of deaths and from what causes, as well as particulars by color, sex, and age, and other vital facts. Vital statistics record the progress which is made in public health. We propose to present for discussion, certain facts relating to births and deaths from the standpoint of a county health department.

Among the American Colonies, Massachusetts was the pioneer in the inauguration of a system of vital book-keeping. A law was passed in 1692 which required the town clerk to register marriages, births, and deaths. This state, in 1842, enacted a registration law which was amended in 1844. The Secretary of the Commonwealth was made the custodian of these records.¹

Records of the early meetings of the American Public Health Association show that vital statistics was one of the subjects which received the serious consideration of the members. Through

activities of the American Public Health Association, The American Medical Association, and other interested organizations, the "Model Law" for vital statistics was developed in 1907. The "Model Law" designates the state as the primary registration unit. With certain exceptions, this work is a function of the state health department. Either the state health officer or some member of his staff is the state registrar of vital statistics.

States are divided into registration districts with cities, towns, townships, villages, or other units comprising a primary registration district. The local registrar may hold his office by reason of his appointment or election as a town, village, or city clerk, or may be appointed for a definite term by the state health officer or state registrar. For efficient service, the latter method is to be preferred.

Transportation was a serious problem when the Model Law was developed. Large numbers of registration districts were organized which would not be required under present conditions. As new communities developed into cities and villages and were incorporated, additional districts resulted. Consequently, there has been a gradual increase in the number of registration districts. In some counties there may

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-Seventh Annual Meeting, Kansas City, Mo., October 25, 1938.

be less than 10 districts, while in others the number may reach 50 or 60, or more. The additional registration districts have materially increased the work of state divisions of vital statistics.

In order to simplify registration, one individual may serve as the registrar for several districts. The following will illustrate this suggestion. One New York State town has an area of 129.5 square miles. In this town are 15 incorporated villages and one city. The town clerk is the registrar for the rural area as well as for 13 of the incorporated villages. We have been informed this arrangement is agreeable to all persons concerned, although the office is not centrally located. If local registrars do not forward their reports promptly, the work of the state registrar in checking and tabulating the returns is delayed. A further delay may be experienced in the classification of certificates, due to the omission of necessary data. This is especially true as relates to the medical and statistical particulars of death. Due to the volume of work done by a division of vital statistics and the delays experienced in securing complete reports, it is not unusual for a period of weeks or months to elapse before detailed summaries are available. This is not a criticism of any division of vital statistics, but a statement of fact. It is not generally realized that there is a considerable interval between a rural death from some preventable cause and its tabulation by the state health department. Numerous miles and many months may intervene.

In recent years local full-time health services have assumed a new importance in the nation's health program. In these health departments are qualified and trained experts, not only in communicable disease control, sanitation, child and maternal health, but in other specialties, including vital sta-

tistics. The full-time health department provides a definite integrating agency between the event of a birth or a death and its tabulation, which has not previously been available to the statisticians. It is logical, therefore, that the county health department, operating on a full-time basis and with qualified personnel, should be recognized and have a significant part in the vital statistics program.

The county health department may serve as the collecting agency in two ways: First, if the county is small in area, it may be designated as a registration district with the health officer as the registrar. He is then responsible for the collection of birth and death certificates, their local registration and prompt transmission to the state registrar at the close of the month. However, the county with so limited an area as to have but one registration district will be the exception. A second method will apply to counties having more than one registration district. Arrangements may be made for birth and death certificates to be transmitted to the state health department through the county health department. This may be accomplished by an informal agreement or by an administrative order issued by the state health officer under which local registrars would forward certificates to the county health department without delay after the data have been copied in the register. The county health department would thereupon make copies for file and transmit the original certificates to the state registrar at the close of the month.

The latter method will be placed in operation in Nassau County, N. Y., in the near future. The state registrar of vital statistics will notify the local registrars of the State Health Commissioner's administrative order effecting the change. A representative of the State Health Department will call on each of the local registrars to discuss

the new arrangement and to answer any questions. In all other respects, the system of registration will remain unchanged. Local registrars will forward to the State Health Department the usual report card showing the number of certificates received during the month, or if no certificates were received, a card containing a statement to that effect.

Since the area of a county is small in comparison with that of a state, the health officer may easily communicate with local registrars by personal call or telephone. On the other hand, registrars will find it possible to utilize the services of the health officer or his staff when confronted with technical questions on registration.

As certificates are received in the office, file or index cards are prepared for each birth and death. Certificates are checked for completeness of information. With the approval of the state registrar, the health officer may query statistical and medical particulars, or other data which have been omitted.

The file card for a birth should be of sufficient size that additional particulars may be entered, such as a record of immunization or vaccination reported by the attending physician or from clinics; the occurrence of communicable diseases, as well as other information relating to the health of the child. This card, in reality, may be a life history of the child as long as he lives in the county.

Each nurse is furnished a record of the births reported in the district to which she is assigned. She will arrange a regular schedule of visits to these homes and will supplement the advice of the attending physician by actual demonstrations in the care of the baby. The nurse, as soon as the baby has reached the age for the application of certain preventive procedures, will stress the importance of those measures,

and the information will be entered on the record card as soon as the child has been immunized or vaccinated. It is anticipated that the nurse eventually will have knowledge of the personal health of not only the babies in her district, but also of the preschool and school group. A record will be available of all visits made by the nurse, and if any unusual condition should occur, this record will show whether or not she has made her calls at the homes involved.

Statisticians will agree that the use of a prophylactic for ophthalmia neonatorum is of great importance to the local health department. Each birth certificate may be reviewed to learn if the preventive was used. If any physician or midwife is not using it routinely, the local health department will be in a position to demand compliance with the law.

Health officers should have immediate and accurate knowledge of all deaths. Daily receipt of these certificates provides this information and allows an investigation of such fatalities, if such is necessary. Communicable disease deaths are checked against case reports. If the case is not of record, it will be possible for the health officer to confer with the physician, secure the report and also learn why compliance was not had with the communicable disease regulations.

It is to be presumed spot maps of the major infectious diseases such as diphtheria, typhoid fever, scarlet fever, measles, whooping cough, pneumonia, and tuberculosis are kept in every health department office. If so the record of deaths may be shown by substituting a different colored tack to that used to show the case. Of equal importance is a spot map for infant deaths. By use of this method, it will be possible to visualize their distribution.

The circumstances of maternal and

infant deaths should be as thoroughly investigated as those due to communicable diseases. Prompt receipt of these certificates will permit such investigations, whereas, if they are forwarded direct to the state health department several weeks may elapse and necessary supplemental information may be forgotten.

All deaths from causes other than communicable diseases should be routinely checked against the syphilis and tuberculosis register. It will not be unusual to find an occasional report of a death from causes other than the two diseases and the case report may be removed from the register.

In the local health department it will be possible to review death certificates of individual physicians if occasion demands. Such certificates may be studied over a stated period and if there are repeated inaccuracies, a personal call to the physician's office may adjust these particulars. The same procedure will apply to causes of death, if vague and indefinite terms are used. We believe this will stimulate physicians to include greater detail of the causes of death on the certificates which they sign. The full-time health department should thus increase the accuracy of the original records on which statistics depend. Even though the tabulation may be accurate as to the certificate received, primary accuracy is essential. There is no more efficient method of improving the accuracy of certificates than by utilizing the services of the county health department.

The performance of autopsies may be stimulated by the health officer who is interested in obscure causes of death. Personal contact to establish this procedure is not possible from the state health department.

It has been said: "There are potential accident hazards in every field of human activity and in every individual act. Disorder in the home, improper

driving, the careless hunter, the unguarded machine—are but a few of the all-pervading causes of the accidents which each year kill 75 to 85 of every 100,000 people and injure 100 times as many. No occupation, no recreation, no avocation is secure from the oftentimes disastrous consequences of unsafe practices.²

Accident prevention has been recognized for years as essential to good operation. As a result, industry has achieved remarkable results in the reduction of accidents among its employees. While these accidents have declined, those due to motor vehicles, to home causes, or in public places have increased. It is only within recent years that there has been a real interest in the prevention of accidents other than those which are incident to industry.

Accidents may be prevented. To develop an intelligent preventive program, information must be available as to where and under what circumstances these mishaps occur. Within the past few years a number of state health departments have inaugurated special studies of fatal accidents which were made possible only through access to death certificates. Primarily, the state must take the initiative and supervise such studies, but of necessity must secure assistance from the communities where the fatalities occur. No other unit of the county government is as well equipped to secure this information as the health department. The work requires the active interest of the health officer and his staff. Of especial value in securing this information and also in advancing the cause of safety is the public health nurse. Field nurses, or other field personnel will secure greater details of the accident than would be contained in the report of the medical examiner, or than could be secured by correspondence.

Valuable use will be made by the

county health department of the vital statistics data on birth and death certificates. There is an advantage in having these data centralized, in order that such information as may be requested will be supplied without delay. The reading public is interested in health conditions, and especially in those factors which relate to mortality. Frequent and complete details on both births and deaths may be prepared and released to the public press.

The health officer will find it possible with such data to evaluate more properly the progress in public health work in his county. Consequently, in participating in vital statistics registration the county health department increases the efficiency not only of its own program, but also its services to the public.

Outbreak of Encephalitis in Man Due to the Eastern Virus of Equine Encephalomyelitis*

ROY F. FEEMSTER, M.D., DR.P.H., F.A.P.H.A.

Director of the Division of Communicable Diseases of the Massachusetts Department of Public Health, Boston, Mass.

ABOUT the middle of August, 1938, cases of encephalomyelitis in horses were recognized in Massachusetts and it was soon ascertained that an epidemic of considerable proportions existed. On August 12 a child from Brockton died of encephalitis, and when a second child from the same city died on August 30 a rumor spread that the two had been victims of the disease prevalent among horses.

On September 1 the Massachusetts Department of Public Health began to be bombarded with questions as to the truth of the rumor. The answer given was that there had never been an authenticated case of human disease due to the equine virus. On September 2 a death from encephalitis was reported in a child from Marshfield, not far from Brockton. On the same day it was learned that a child, reported on August 31 from Abington as poliomyelitis, had been sent to the Haynes Memorial Hospital where a diagnosis of encephalitis was made. Likewise, on the same day a telephone request was received for aid in making a diagnosis of an illness in a child from Rockland. A consultant of the department, sent to see the case, found that the symptoms were those of encephalitis.

All five of these cases occurred within 15 miles of each other, the nearest being 20 miles southeast of Boston. An interesting coincidence was that they had occurred in essentially the same area as the equine disease. Because of this fact and also on the chance that this was just the beginning of an outbreak similar to the one at St. Louis, the department arranged for virus studies on any fatal cases that might occur. Over the Labor Day week-end the child, seen by the department consultant and transferred to the children's Hospital, died. Two other cases admitted to the Haynes Memorial Hospital on September 1 and 3 also proved fatal. Brain tissue from the first case was put into experimental animals in the Department of Bacteriology of Harvard Medical School, and brain tissue in glycerine from all three was sent to the Rockefeller Institute at New York.

NOTE: The author is merely acting as spokesman for the Department, most of the members of the Division having taken part in the investigation. The Department wishes to acknowledge its indebtedness to Dr. J. E. Gordon, Dr. C. F. McKhann, and Dr. S. Farber of Harvard Medical School and the Children's Hospital for assistance in guiding the investigation and evaluating the epidemiological, clinical, and pathological findings; to Dr. L. D. Fothergill and his associates of Harvard Medical School and Dr. L. T. Webster of Rockefeller Institute for making virus studies; to Dr. C. Wesselhoef and Dr. E. C. Smith of the Massachusetts Memorial Hospitals for information in regard to their cases; and to Dr. James P. Leake of the U. S. Public Health Service, and Lt. Col. J. S. Simmons and Lt. Col. Raymond Randall of the Office of the Corps Area Surgeon, First Corps Area, Boston, for valuable suggestions and information.

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

During the next few days a number of additional cases of encephalitis were discovered in the same area, and brain tissue from other fatal cases was obtained for virus study.

Information was received by the Massachusetts Department of Public Health simultaneously from Fothergill, Dingle, Farber, and Connerley¹ of Harvard Medical School and the Children's Hospital, and Webster and Wright² of the Rockefeller Institute that the eastern strain of the equine encephalomyelitis virus had been isolated from the brain tissue. The investigation immediately assumed a new importance. The existence of a new human disease had been established. The virus is known to be widespread in horses along the Atlantic coast. If the western strain can also cause human infections, a public health problem of some magnitude may confront us.

The U. S. Public Health Service had been informed of the increased prevalence of encephalitis, and when cases were definitely proved to be due to the equine virus Dr. James P. Leake and an entomologist were sent to Boston to aid in the investigation. Because Kelser³ and others had demonstrated that mosquitoes can transmit the disease in laboratory animals, a mosquito survey* was begun on September 19. It was found that *Aedes* mosquitoes, the probable vector among horses, had already practically disappeared for the season. *Culex pipiens* was the mosquito most frequently encountered in the area. Mosquitoes were collected in homes of cases and around stables where fatal disease in horses had occurred, in the hope of discovering some that might be carrying the virus. So far no virus has been recovered from such mosquitoes.

THE DISEASE AMONG HORSES

While the etiology of equine encephalomyelitis in this country was not definitely established until 1930, it is believed that outbreaks had been occurring in previous years. Conditions formerly called forage poisoning and botulism are mentioned by Meyer as probable cases. When the disease became epidemic in Southern California in 1930 and 1931, Meyer and his co-workers isolated the virus⁴ and described the disease⁵ and its pathology.⁶ When cases were recognized in the East it was noted that the case fatality rate was twice as great east of the Appalachian Mountains. This led workers to suspect that a different virus was present in the East. Ten Broeck and Merrill⁷ and Howitt⁸ have demonstrated that the eastern and western strains are immunologically different from each other and also different from the strain causing Borna disease in Europe which had been proved to be due to a virus in 1926.⁹ Strains from Argentina and certain other South American areas behave the same as the western strain. Those from Panama are identical with the eastern strain.

There is very little evidence that the disease has been present in New England in recent years. Veterinarians now believe that cases occurred in Massachusetts in about 1913 and 1914 and that the highly fatal epidemic among horses in 1872 was probably encephalomyelitis. The disease, however, is known to have been present in various states along the Atlantic seaboard from Florida to New York in recent years.

While the disease among horses was not definitely recognized in Massachusetts in 1938 until after the middle of August, it was eventually found that cases had occurred in that state as early as July 12 (one questionable case reported June 4). The number increased with considerable rapidity, reaching a peak in the week ending August 27 and

* Valuable assistance in the survey was rendered by Virgil I. Miles, entomologist, of the U. S. Public Health Service.

rapidly decreasing thereafter (Table I). The number of cases reported to the Massachusetts Division of Livestock Disease Control has now reached 251. This probably does not represent all of the cases, since horses must have died without coming to the attention of veterinarians. Other delayed reports continue to come in. The number of horses on the tax lists in the counties

(Table II) most seriously affected was 5,738 (Bristol, Norfolk, and Plymouth Counties). The total number of cases reported from these counties was 204, which gives an attack rate of about 3.5 per cent (see map). This compares with 10 per cent noted by Meyer⁵ in California at the time the causative organism was first recognized.

The disease appeared to be unusually fatal, very few recoveries being reported. It is estimated that well over 90 per cent of the horses affected have died. The eastern strain has been isolated from the brains of 6 horses. It is definitely known, therefore, that the disease in Massachusetts in both man and horse is due to the eastern strain. Schoening¹⁰ has just been able to produce the disease in a horse with a virus from one of the human cases.

Kelser³ and other workers have demonstrated that several varieties of *Aedes* mosquitoes can transmit either the eastern or western strain of the virus in laboratory animals. Three of the varieties (*Aedes sollicitans*, *Aedes vexans*, and *Aedes cantator*) are usually found in considerable numbers in Massachusetts, and a fourth (*Aedes dorsalis*)

has been reported occasionally. If the mosquito is the vector of the natural infection in horses, the spread of the disease in the state can easily be accounted for once a case is introduced.

DISTRIBUTION OF HUMAN CASES

It is, of course, impossible at present to state how many cases of encephalitis due to the equine virus have occurred in the state during the outbreak. Some 38 cases have been under investigation.

These are being classified into 4 groups as information becomes available:

I. Cases proved by isolating the virus from brain tissue taken at post-mortem. Thus far, 8 cases* have been so identified.

II. Cases in which the gross and microscopic pathology is characteristic. Including the 8 cases from which virus was recovered, fifteen cases already examined fall into this group.

III. Recovered patients who show neutralizing antibodies in the blood. Specimens have been collected from several individuals who have survived illnesses in which symptoms compatible with the disease were observed. Four of these have shown high titers of neutralizing antibodies, two were negative and the remainder have not yet been examined.

IV. Patients who have died without an autopsy, but in whom the clinical picture seems suspicious. Additional information on these cases may come from the examination of bloods taken from contacts. If neutralizing antibodies are found, infections caused by the virus in the family will be indicated.

Theoretically there should possibly be a 5th group: cases from which the virus is isolated from the blood or

* Four of these died at the Haynes Memorial Hospital, 2 at the Children's Hospital, 1 at the Truesdale Hospital, Fall River, and 1 at St. Elizabeth's Hospital, Boston.

spinal fluid early in the disease. So far, all specimens of this kind have failed to yield a virus. Meyer¹¹ and Ten Broeck¹² and their coworkers have observed that the virus is found in the blood of experimentally inoculated animals during the period of invasion and rise in temperature, but disappears before any symptoms are observed. Virus has not been recovered from naturally infected horses. It seems unlikely, therefore, that human cases will be seen early enough to obtain virus from the blood.

It is quite certain that some of the cases under investigation will have to be thrown out either because another diagnosis will be established or because evidence will not be sufficient to classify them into any of the 4 groups. This should be borne in mind in interpreting the following tables.

It will be noted (see maps) that there was a marked concentration of cases within the area where the equine disease was prevalent. Search was made among hospitals and physicians in other parts of the state to make sure that cases were not being overlooked elsewhere, but no additional ones were found. The earliest cases under investi-

gation had onsets (Table III) early in August and the peak occurred early in September, a week later than the peak of the disease among horses.

The cases are fairly evenly divided between the sexes (Table IV). The age distribution, on the other hand, is quite striking. Children under 2 years seem particularly vulnerable, 37 per cent of the cases being in that group. One-half were under 5, and 69 per cent under the age of 10.

The families in which cases have occurred have been visited and epidemiological records obtained. Suspicious illnesses have occurred in some, but multiple or secondary cases of frank disease in families have not been found.

No connection between cases, indicating contact infection, has been traced. Contact with horses has been only casual in many of the cases and no contact at all can be discovered in others. No epidemics among small animals have been observed in the vicinity of the households. Rhode Island Red chickens were found at, or in the vicinity of, many households but, since a large proportion of the cases lived in the more sparsely settled areas, this is probably to be expected. Practically every family had taken trips to nearby communities on motor rides, picnics, or visits to beaches.

Mosquitoes were unusually prevalent this summer because of heavy rains in July, and there is a universal history of mosquito bites. In a few cases, unusual reactions to such bites have been observed. This probably means that many varieties of mosquitoes were present this year since no local reactions due to the equine virus have as yet been described as occurring.

CLINICAL DESCRIPTION OF CASES *

The following summary gives the most common symptoms and signs which characterized the disease as seen at the Boston Children's Hospital and the Haynes Memorial Hospital. Cases occurring in other hospitals were similar in most details.

The onset in infants was sudden, with fever, irritability or drowsiness, cyanosis, and convulsions. In older children and in the one adult the symptoms were of slower onset, from 4 to 10 days. In 2 cases there was a definite remission of the symptoms lasting for 1 day. Headache, frontal in character, and dizziness were the first complaints in the older patients. In 2 infants diarrhea preceded the other symptoms, while vomiting occurred in

half of the cases. All patients were semi-comatose to comatose on admission, and the majority showed continued tremors or muscular twitchings. Rigidity of the neck was a constant feature, as was a tense anterior fontanelle in the infants.

Evidences of an upper respiratory infection, *e.g.*, pharyngitis and otitis media simplex, were found in few of the cases. The suppression of the cutaneous reflexes was constant in the comatose patients, while the Kernig and kindred signs varied markedly. Facial palsies were seen in 3 cases, one of which had in addition a hemiplegia.

Outside of the fact that the pupils reacted sluggishly to light and one patient complained of photophobia, no abnormal eye findings were noted.

The temperature was invariably high, 102 to 104°, and in the fatal cases continued to rise. Where recovery took place the fever fell by lysis, becoming normal in 4 or 5 days.

The spinal fluid showed increased pressure, average 240 mm., hazy to ground-glass in appearance; the cell count varied from 200 to 2,000, of which 60-90 per cent were polys. Total protein was high, 95-185 mg.; sugar normal or slightly increased. Smears and cultures showed no organisms.

The blood showed the same polymorphonuclear response. The white count varied from 14,600 to 65,900, the percentage of polys from 75 to 90. The counts above 35,000 were in children who also had whooping cough.

When the patient lived over 2 or 3 days, there was a drop in both the spinal fluid and white blood counts, with a change to the mononuclear type of cell.

Convulsions and muscular twitchings marked the course of the disease. In the infants a peculiar edema developed about the eyes and in the upper extremities. Cyanosis was marked in all cases.

Deep coma from which the majority

* This summary was obtained from Dr. Charles F. McKhann and Dr. E. C. Smith.

of patients never aroused developed shortly after admission. When a patient survived the acute stage, coma and more or less rigidity of the muscles persisted for many days. An occasional patient showed gradual but slow improvement, returning apparently to normal.

Some cases suspected of being due to the virus have made complete recoveries, but it appears that certain other cases will show paralyses, mental changes, and other permanent residuals.

GROSS AND MICROSCOPIC PATHOLOGY *

Severe edema and congestion of the brain and cord, flattening of the convolutions and the formation of pressure cones in the cerebellum were conspicuous gross findings. On microscopic examination all parts of the brain showed some degree of involvement, with maximum changes in the brain stem. The lower cord was rarely involved except for edema and congestion. The anterior horn cells were spared.

The microscopic changes may be divided into several groups: (1) perivascular accumulations of large numbers of polymorphonuclear and large mononuclear cells; (2) diffuse slight infiltration of the meninges by the same types of cells; (3) numerous scattered focal areas of nerve cell destruction with infiltration by polymorphonuclear and microglial cells; and (4) small thrombi in vessels which often exhibited intramural degeneration and fibrin deposition.

The predominant type cell in the exudative response changed to the large mononuclear cell as the acute reaction subsided in cases where 6 to 20 days passed between the onset of important symptoms and death. After the longer duration of the disease, the perivascular infiltration and meningeal reaction almost disappeared, the areas of neuronophagia were less prominent, and

the main picture became one of removal of debris and repair.

No bacteria were found by cultural methods or by histologic examination of the brain with the aid of appropriate stains in one patient who died 48 hours after the onset of symptoms.

Widespread congestion was present in the viscera. Numerous small thrombi were found on microscopic examination in many organs of the body. No bacteria could be demonstrated in relation to these thrombi. Severe pulmonary edema and congestion, probably secondary to the inflammatory process in the brain stem, were present in patients in whom no secondary bacterial infection could be demonstrated.

In summary, examination of the central nervous system demonstrated a severe, diffuse acute meningo-encephalitis, characterized chiefly by an intense polymorphonuclear and mononuclear cell infiltration in the perivascular spaces and to a minor degree in the meninges, and by widespread destruction of nerve cells.

DISCUSSION

As early as 1931, Meyer⁵ suggested the possibility of humans contracting the equine disease. He noted in 3 individuals illnesses suspected of being due to the virus. The brief account of symptoms and findings in the fatal case is consistent with the clinical picture seen in the Massachusetts cases, particularly the finding of polymorphonuclears in the spinal fluid. The 8 cases in Massachusetts, however, are the first human infections definitely proved to be due to the equine virus. An entirely new public health problem has been opened up and the equine disease assumes an added importance.

The disease in the severer form is sufficiently different from the usual varieties of encephalitis to be recognized clinically. If some of the milder cases under investigation prove to be

* This summary was obtained from Dr. Sidney Farber.

due to the same virus, and particularly if the existence of subclinical infections can be established, the recognition of all cases will be difficult unless laboratory means of verifying the diagnosis can be found. A routine test within the scope of the public health laboratory would be invaluable. Whether the neutralization test or some similar procedure will be the solution is yet to be demonstrated.

A number of other problems in regard to the disease await elucidation. We need to know if other reservoirs beside the horse are important. In fact, Ten Broeck¹² and his coworkers suggest that the horse may not be the primary host, both because the disease is so highly fatal and because the virus disappears from the blood so early. Fothergill¹³ has just isolated the eastern virus from a dead pigeon from an area where many pigeons have been dying this summer. It yet remains to be satisfactorily demonstrated that the mosquito transmits the natural infection among horses. The importance of other insects, especially the recently incriminated tick, as vectors of the disease awaits investigation.

The need of having all cases of encephalitis reported to health departments is emphasized by the presence of the equine infections in humans. The Massachusetts Department of Public Health has now made all cases of "Infectious Encephalitis" reportable instead of the former designation of "Encephalitis Lethargica."

SUMMARY

1. Eight cases of human encephalitis have been proved to be due to the eastern virus of equine encephalomyelitis.

2. The clinical picture and pathological

findings in these cases appear to be sufficiently characteristic to make recognition of the disease possible.

3. While young children seem to be particularly vulnerable, adults are occasionally affected.

4. The case fatality appears to be high; 25 of the 38 cases under investigation died.

5. The attack rate among horses was low (3.5 per cent) but the case fatality was high (over 90 per cent).

Rocky Mountain Spotted Fever and Tick Survey in Iowa*

CARL F. JORDAN, M.D., C.P.H., F.A.P.H.A.

*Director, Division of Preventable Diseases, and Epidemiologist,
Iowa State Department of Health, Des Moines, Ia.*

ROCKY Mountain spotted fever, now known to have widespread distribution in the United States, has in recent years assumed greater significance for the northern as well as the southern central states.

REPORTED IN CENTRAL STATES

Hampton and Eubank¹ of the U. S. Public Health Service, recently reported that during the 5 year period 1933-1937, cases of spotted fever totalling 2,190 were notified for the United States as a whole. The Mountain and Pacific states reported 65.5 per cent and the South Atlantic group of states, 27.4 per cent of all cases. Of the remaining 7.1 per cent, 5.4 per cent occurred in the North and South Central States, and 1.7 per cent in the New England and Middle Atlantic states. In the period 1933-1937, the East and West North Central states reported 80 cases with 17 deaths, as compared with 36 cases and 10 deaths in the East and West South Central states. The 4 groups comprising the Central states, reported 47 cases in 1938 (to September 1), representing more cases than have been reported in any previous year.

The first case of Rocky Mountain spotted fever in Iowa was officially re-

ported to the State Department of Health in June, 1933, by C. N. Freligh, M.D. of Waucoma, Fayette County. Much credit is due to the attending physician who is first to recognize a disease which previously was not known to occur in his state. To date, 38 cases of spotted fever have been officially reported in Iowa.

CLINICAL MANIFESTATIONS

Excellent accounts of the clinical manifestations of Rocky Mountain spotted fever have been published in recent years by Rumreich, Dyer, and Badger² of the U. S. Public Health Service, by R. R. Parker,³ Director, Rocky Mountain Laboratory of the U. S. Public Health Service at Hamilton, Mont., by Litterer⁴ in Tennessee, by Stroy,⁵ Floyd⁶ and others in Iowa, and by many other physicians and investigators. In the cases studied in the state, onset of illness has usually been sudden, sometimes beginning with a chill. Symptoms and signs include fever, headache, vomiting, abdominal pain, neck stiffness, weakness or prostration, and drowsiness which may progress to coma. On the third day, as a rule, reddish spots, irregular in outline and varying in size from one to several millimeters, appear about ankles, wrists, and forehead, later extending to the body and becoming generalized. The color of the lesions deepens with rise in temperature. Macules later become

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

petechial in character and remain visible for 1 week to 10 days or longer. Brownish discoloration occurs before the eruption fades and disappears. Increased reflexes and ankle clonus are, when present, significant findings referable to the central nervous system.

Some of the cases have been of comparatively mild, others of severe type. Nine deaths have been recorded in Iowa during the past 6 years, a case fatality rate of nearly 24 per cent. Three deaths from this cause occurred in 1937, no fatalities in 1938. One patient recovered from the acute illness, but developed epileptiform attacks, a sequela which ran a progressive course with fatal outcome 3 years after onset of symptoms.

In the 38 cases reported, clinical findings were confirmed in 27 instances by positive Weil-Felix agglutination tests, varying in titer from 1-160 to 1-1,280. In 4 cases, diagnosis was based on characteristic clinical findings plus the history of a tick having been removed from the body shortly before illness. Diagnosis in the remaining 7 instances, was based on the clinical picture, together with the history of possible exposure to tick bite. An additional aid in recognition of some of the early cases which occurred, was the demonstration of immune substances in the patient's serum, by means of the protection test, completed in the Rocky Mountain Laboratory of the U. S. Public Health Service.

EPIDEMIOLOGICAL FACTORS

Among 38 cases reported to the Iowa State Department of Health in the 6 year period 1933-1938, 25 patients were males, 13 were females. Nearly half of the cases were children between 1 and 9 years; nearly a third were persons from 40 to 80 years of age. The youngest patient was 17 months, the oldest 79 years.

Four of the 38 patients had onset of

symptoms in May, 18 in June, 11 in July, 4 in August, 1 in September. Onset of illness of the earliest case in the season was May 16, of the latest in the season, September 6.

Cases were reported from 18 counties, representing widely scattered sections of northeastern, eastern, southeastern, southern, southwestern and central Iowa.

That Rocky Mountain spotted fever represents a distinctively rural health hazard is indicated by the cases thus far reported. In the series of 38 patients under consideration, exposure in 32 occurred on a farm or in a rural area, including 2 boys who lived in town but were visiting relatives on the farm at the time of illness. Five other patients were urban residents who gave a history of direct or possible exposure to ticks. One patient was a packing house employee who might have been exposed to ticks through the handling of hides or through proximity of his residence to open country.

OCCURRENCE OF MULTIPLE CASES

On 3 occasions, 2 members of a family had onset of illness at the same time. In a 4th instance reported by Stroy,⁵ 3 children in the same farm household took sick within a few days of each other. The youngest child died, the second was severely ill, while the oldest had a mild attack, the nature of which under other circumstances might easily have been overlooked.

In 1937, an outbreak of Rocky Mountain spotted fever occurred among Indians on the Sac and Fox Reservation in Tama County. Six cases were reported within several weeks by Ira Nelson and A. A. Pace, physicians in the Indian service. Two of the patients were Indian women, both of whom recovered; 4 cases were children, of whom 2 died. All the patients had been directly exposed during the days immediately preceding illness, to the common dog tick, *Dermacentor variabilis*.

Control measures on the reservation were directed primarily against dogs, many of which were heavily infested with ticks. Special efforts were put forth to rid dogs, in so far as possible, of tick infestation. Treatments with spotted fever vaccine were administered to many of the 450 Indians. Prior to the opening of the tick season in 1938, control measures were renewed and spotted fever vaccine was given to about a third of the Indians, including most of the children. The vaccine was forwarded through courtesy of Dr. Parker, from the Rocky Mountain Laboratory at Hamilton, Mont.

RESULTS OF TICK SURVEY

During 1936-1937, a tick survey was carried out under auspices of the Iowa State Department of Health, instituted by Walter L. Bierring, M.D., Commissioner, in collaboration with Carl J. Drake, State Entomologist, and R. R. Parker, Director of the Rocky Mountain Laboratory.

In June and July, 1936, ticks were collected by Dean Eckhoff, Assistant Consulting Entomologist, in 35 counties of the state. Of the ticks forwarded from Iowa to the Montana laboratory, about 350 arrived in good condition. The report from Dr. Parker⁷ stated that all specimens belonged to the species *Dermacentor variabilis*, or the common dog tick. Tests carried out on guinea pigs and consisting of the injection of tick substance from 30 groups of ticks, proved negative for evidence of spotted fever virus. *Bacterium tularensis* was recovered from ticks collected in 3 counties in southeastern Iowa, 2 of the 3 batches of ticks having been removed from dogs.

The tick survey was resumed in the late spring and early summer of 1937, and included 18 counties in the southern half of the state. Ticks collected by dragging the vegetation with canvas and designated "drag" ticks, totalled

3,026. Engorged ticks removed, chiefly from dogs but also from cows, horses and smaller wild animals, numbered 2,832. The conduct of the survey afforded opportunity to make some interesting observations pertaining to habits of the American dog tick and regarding some of the animal hosts preferred by the nymphal and adult ticks. Mr. Eckhoff's report reads in part as follows⁸:

Concerning the host I can positively list rusty fox squirrel, cottontail rabbit, and woodchuck as being host to the last stage nymphal and adult ticks in Iowa. Several smaller mammals were examined but I did not find any stage of the tick. The domestic animal host list includes horse, cow, sheep, goat, dog, and infrequently, cat.

Mr. Eckhoff observed that ticks were seldom found in the woods away from paths or roads but

... were concentrated on blue grass, sweet clover, weeds and shrubs growing through the dead leaves in roadside ditches.

It is significant that among the ticks collected in Iowa during 1937 and tested in the Montana laboratory, ticks from the Tama Reservation and from the farm in Clarke County where 3 children in the same home developed spotted fever, proved to harbor the virus of Rocky Mountain spotted fever.

RESULTS OF WEIL-FELIX TESTS

Agglutination Tests on Human Serum—In connection with the outbreak of Rocky Mountain spotted fever which occurred among the Indians in Tama County in 1937, efforts were made to determine whether apparently healthy persons might show evidence of latent infection resulting from exposure to spotted fever virus. The Weil-Felix test with the use of *B. proteus* X₁₉ as antigen, was performed on 189 serum specimens obtained from Indian men, women, and children, several weeks following the outbreak. Although 4 serum specimens showed agglutination

in the 1-80 dilution, these reactions were not sufficiently high to be regarded as diagnostic. The Weil-Felix tests were performed under the capable direction of I. H. Borts, M.D., Assistant Director of the State Hygienic Laboratory.

Agglutination Tests on Serum of Dogs—A house-to-house canvass on the Indian Reservation was conducted by Frank J. Condon, M.D., Medical Director of Health District No. 2, assisted by Mr. Eckhoff. Among about 100 dogs belonging to the Indians, 60 were found to be infested. Ticks totalling 1,880 were removed from all of the dogs. Blood specimens were taken from 80 dogs and sent to the State Hygienic Laboratory. The antigens used by Dr. Borts for the Weil-Felix tests included the Washington strain of proteus X₁₉ and live strains of OX₁₉ Parker and OX₂ Parker. The OX₂ antigen is regarded as being very sensitive, yielding higher titers than other strains. Although 5 of the sera produced agglutination of the Parker OX₂ antigen in dilutions 1-160, reactions with the two other strains were not sufficiently high to be regarded as diagnostic. Six of the serum specimens showed a doubtful reaction for tularemia 1-40 and two specimens were positive for this infection in the 1-80 dilution.

DISCUSSION

In the 38 cases of Rocky Mountain spotted fever reported in Iowa in recent years, there is evidence in 14, or 37 per cent of the cases, to indicate that dogs play an important part in relation to the spread of spotted fever from infected ticks to human beings. Dogs serve as a drag net in gathering ticks and bringing them close to children and adults in the home. As an example, in an Indian home in which 2 children developed spotted fever, ticks numbering 275 were taken from 4 dogs belonging to the family. Experiments reported by Badger⁹ show that dogs

are susceptible to spotted fever virus. It is possible that further investigation may demonstrate that the dog as a host of *Dermacentor variabilis*, plays a more significant part than is now realized, in the transmission of Rocky Mountain spotted fever to man.

SUMMARY AND CONCLUSIONS

1. More complete reporting of Rocky Mountain spotted fever is dependent upon attending physicians who are spotted fever conscious and upon repeated laboratory tests for confirmation of the clinical diagnosis.
2. Educational measures need to be continued, so as to make people who live in or frequent rural areas, more tick conscious during the tick season.
3. Results are reported of a tick survey in Iowa.
4. More precautions need to be exercised to minimize the hazard of transmission of tick-borne disease through the agency of tick infested dogs.
5. It is desirable that there be further study of the common dog tick, *Dermacentor variabilis* and of the epidemiology of Rocky Mountain spotted fever in the Central states.

NOTE: Special acknowledgment is made to R. R. Parker, Director, Rocky Mountain Laboratory of the U. S. Public Health Service, for his willingness to undertake the expensive and laborious task of testing some of the ticks collected in Iowa, for sending spotted fever vaccine and for his valuable suggestions relating to the subject of Rocky Mountain spotted fever.

The Probable Typhoid Carrier Incidence in Mississippi*

A. L. GRAY, M.D., M.P.H.

*Director, Division of Preventable Disease Control, State Board
of Health, Jackson, Miss.*

THIS paper is a part of the result of an honest effort to determine what the typhoid fever control problem is and may be expected to be in Mississippi. For this effort to be even partially successful, it was desirable to know the approximate incidence of typhoid carriers in Mississippi. No refined statistical maneuvers were used in coming to conclusions, and it is admitted that more accurate methods might have been used. Facts presented were accumulated over a period of 4 years' experience in doing the proverbial "shoe-leather," or I might say cotton-field, epidemiological studies on typhoid fever in Mississippi.

It has long been recognized that typhoid carriers play an important part in maintaining the incidence of typhoid fever in a given area. A typhoid fever control program to be ultimately successful must embrace thorough persistent search for carriers and provision for continued adequate supervision of them. Plans for a control program should be based upon several factors, among which are current and past incidence of the disease and incidence of typhoid carriers. Obviously the inci-

dence of typhoid carriers in an area is dependent upon the past prevalence of typhoid fever in that area. The difficulty is to determine what the actual incidence in the area has been and to know just what percentage of those having the disease become permanent carriers. Neither of these problems has been satisfactorily solved.

Mississippi is in the heart of the old South, along the east bank of the lower Mississippi River. It has a population of slightly over 2,000,000 of which about 49 per cent is white and 51 per cent colored. It is primarily an agricultural area in which cotton production predominates. Lumber manufacture has been and remains a prominent source of income. A very large percentage of the population lives in rural areas and small towns of less than 1,000 population. Because of the relative simplicity in methods of living epidemiological problems are much less complex than in metropolitan areas. About 30 per cent of the population has some type of comparatively safe excreta disposal. A smaller percentage has protected water supply.

The reported incidence of typhoid fever in Mississippi is indicated in Table I and Figure I which show the reported case and death rates per 100,000 population from 1920 to 1937.

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

FIGURE 1

Typhoid Fever Case and Death Rates per 100,000
in Mississippi, 1920 - 1937

Experience in epidemiological study of typhoid fever in Mississippi leads the writer to believe that the actual incidence of the disease has been between 30 and 40 per cent higher than is indicated by reports.

TABLE I

Typhoid Fever Cases and Deaths, Case and Death Rates per 100,000 Population in Mississippi, 1920-1937

Year	Cases	Case Rates	Deaths	Death Rates
1920	2,644	147.8	342	19.2
1921	2,665	147.9	348	19.9
1922	2,230	121.5	337	18.4
1923	1,690	91.0	252	13.6
1924	2,470	131.4	330	17.5
1925	4,415	232.0	470	24.6
1926	2,613	135.7	390	20.3
1927	1,597	81.9	255	13.1
1928	1,517	77.0	237	12.0
1929	1,315	65.9	197	9.9
1930	1,239	61.4	238	11.9
1931	1,059	51.9	211	10.4
1932	928	45.1	145	7.1
1933	529	25.4	135	6.5
1934	490	23.0	66	3.1
1935	366	17.3	61	2.9
1936	377	18.2	96	4.7
1937	344	15.8	77	3.8

Physicians in Mississippi have looked upon typhoid fever as a disease which always causes one to be ill for several weeks. There is no question that many people have typhoid fever with only slight indisposition for a few days. Such cases have either not been seen by a physician or have not been diagnosed.

In 1937, 82 cases of typhoid fever were definitely diagnosed in 11 counties having full-time local health service. Of these 82 cases, 32 were located and diagnosed through the county health officers' epidemiological studies of cases reported by physicians. In other words, over 39 per cent of that group of cases would not have been reported without the investigative efforts of health officers. This type of work has developed within the past 4 years. This is a very definite indication that the actual typhoid fever incidence has been and remains much higher than the reported incidence would indicate.

The method chosen to determine the approximate typhoid carrier incidence is briefly described together with the

TABLE II
Total Surveyed by Age Groups and Race

	0-4	5-14	15-24	25-34	35-44	45-54	55 and Over	Total
White	1,150	2,439	1,812	1,308	1,082	774	809	9,374
Colored	1,253	2,451	1,868	1,281	956	728	666	9,203
Total	2,403	4,890	3,680	2,589	2,038	1,502	1,475	18,577

conclusions reached. The conclusions are based upon the estimated number of people now living in Mississippi who give a history of typhoid fever and the percentage of the cases resulting in a permanent carrier state. To determine the number of people now living with a typhoid fever history, as diagnosed by physicians, a random sample of homes was surveyed, involving 18,577 people in 16 counties with a total population of 603,000. The homes surveyed were without regard to knowledge of previous incidence in the communities. For each county, the survey was planned so as to reach about 3 per cent of the white and colored population respectively. Urban and rural populations were surveyed so as to include proportionate shares of these groups. As nearly as possible, every fifth home was surveyed in several communities in each county and in sections of towns in these counties. It was impossible to make a true random sampling survey, but efforts were made to approach this as nearly as possible.

A responsible person, usually the wife, was questioned as to the typhoid history of each member of the family. Only those were counted as having had typhoid fever who stated that their physician made this diagnosis.

Figure II indicates the area covered. Counties surveyed were those in which other work was being done, the survey being a secondary objective.

Table II shows the number of people surveyed by age group and race.

FIGURE II
Outline Map of Mississippi
Showing Counties Surveyed

Table III gives the number of each age and race group with a history of typhoid fever.

Colored	0.55	4.00	8.00	11.39	16.5	19.09	18.62

Table IV shows the per cent of each age group by race, with a history of typhoid fever.

Table V gives the estimated population of the state as of July 1, 1935, by age groups and race, based upon the 1930 Census Bureau figures and the arithmetic increment from 1920 to 1930; also the per cent and number of each age group and race of the state having a history of typhoid fever and now living.

From the foregoing survey and calculations it is found that in 1935 there were living in Mississippi 183,230 people giving a history of typhoid fever as diagnosed by physicians.

This method of determining the number of living people with history of typhoid fever is liable to several sources of error—one, the fact that no one knows how many of those with history of typhoid fever were properly diagnosed. It is known that comparatively few physicians have used dependable laboratory diagnostic aids in

dealing with typhoid fever. The Widal reaction has been largely depended upon and, in Mississippi, this has comparatively little diagnostic significance.

Experience leads to the conclusion that there have been many cases of typhoid fever that were not seen and reported by physicians. Another large group of cases were seen by physicians but diagnosed by nonspecific terms—such as colitis, flux, malaria fever, etc. It is believed that these two groups far exceed the cases classed as typhoid fever. This is more clearly indicated by the fact that less than 5 cases of typhoid fever for each typhoid fever death were reported in the period 1933 to 1937. It is believed that there are probably 12 to 14 cases per death rather than 8 as reported.

There is no definite proof that there is not a great deal of variation geographically, by race, or by severity of attack as to the percentage of cases developing the permanent carrier state. It is apparent, however, that much of

TABLE V

Age Group Distribution of Population and Recovered Cases of Typhoid Fever Now Living in Mississippi as of July 1, 1935

Age Group	White			Colored		
	Population	Per cent History of Typhoid	No. Living Recovered Cases	Population	Per cent History of Typhoid	No. Living Recovered Cases
0-4	120,392	0.089	107	123,143	0.55	677
5-14	239,368	1.39	3,327	240,499	4.00	9,619
15-24	222,272	2.53	5,623	232,772	8.00	18,621
25-34	151,269	8.00	12,101	153,241	11.39	17,454
35-44	123,250	15.9	19,596	117,532	16.5	19,363
45-54	102,530	19.5	11,893	92,735	19.09	17,703
55 and Over	110,966	26.7	29,627	88,719	18.62	17,519
Total	1,070,047		82,274	1,048,461		100,956

the difference in opinion as to the percentage becoming carriers is due to difference in efficiency of laboratory technic, as well as many other factors too numerous to mention. It has been the experience of workers in Mississippi that results of examination of stool specimens for *B. typhosus* are dependent in no small degree upon the type and age of the specimen.

It is the policy of the Mississippi State Board of Health to class an individual as a permanent typhoid carrier only after securing at least two positive cultures as late as 1 year after onset of the disease. In the past 3 years 286 cases of typhoid fever were definitely diagnosed by finding *B. typhosus* in the blood, stool, or urine. Of the 286 cases 42 died, leaving 244 cases which were followed up with frequent release stool and urine cultures until at least two consecutive negative results were obtained, made not less than a week apart and after recovery. Eight of the 244 continued to excrete typhoid bacilli in stool as late as 1 year after onset, as a result of which they were listed as permanent carriers. Accordingly, 3.27 per cent of this group became permanent carriers.

Findings of different investigators have varied from less than 2 per cent to 7 per cent of recovered cases developing into the permanent carrier state. Several of the 244 cases excreted the organisms 3 to 9 months after recovery and ceased doing so as determined by 12 consecutive monthly specimens.

The survey indicated that there are at least 183,230 recovered cases of typhoid fever living in Mississippi. If we assume this is approximately correct and that 3.27 per cent of them became

permanent carriers, there are now in Mississippi approximately 5,991 carriers who subject the rest of the population to constant danger by spreading typhoid organisms.

The above figures mean that for each 100,000 people of the 2,080,000 living in Mississippi there are about 288 typhoid carriers.

This, together with many other facts, indicates that the problem of typhoid fever control has not been solved nor will it be solved for many years to come.

SUMMARY AND CONCLUSIONS

1. A random survey of 18,577 people in 16 counties in Mississippi revealed that 1,547 gave a history of having had typhoid fever as diagnosed by physicians.

2. Those surveyed were classified by age group and race as to total number in each group, and number in each group giving history of typhoid fever. These classifications were used to determine the percentage in each age and race group with a history of having had typhoid fever. The percentages thus obtained were applied to the total age and race group populations of the state to find the total number of people now living in Mississippi with a history of typhoid fever. According to these calculations there are 183,230 people in the state with such history.

3. Of 244 proved cases of typhoid fever in Mississippi 8, or 3.27 per cent of the group, became permanent carriers and were excreting *B. typhosus* more than 1 year after onset. Applying this percentage to the total recovered cases living in the state, 183,230, there are about 5,991 typhoid carriers in the state at present, or 288 carriers per 100,000 population.

OUR SIXTY-SEVENTH ANNUAL MEETING

MANY of us have visited Kansas City in the past. Those who had not done so were prepared by even the very imperfect sketch in our issue of August to be entertained and charmed. Not only were we not disappointed but our fondest expectations were more than fulfilled.

Our meeting place was the Municipal Auditorium, one of the largest and most perfectly arranged buildings of its kind in the country, with every facility for rooms, exhibitions, and entertainment. It is very near the leading hotels which furnished abundant accommodations for gatherings of practically any size. While the city possesses every convenience for a scientific or business meeting, the residential district, with its many parks, beautiful trees, and magnificent residences, adds a charm which none can ever forget.

As usual, a number of related societies met at the same time, such as the American School Health Association, American Social Hygiene Association, Association of Women in Public Health, Conference of State Laboratory Directors, Conference of State Sanitary Engineers, and the International Society of Medical Health Officers. Most of these had their special sessions the day before our Association convened, as well as a number of joint sessions with our sections.

The program of our own meeting was an interesting one. In the ten different sections of which our Association is composed, many subjects of great general public health interest were discussed by specialists. It may not be amiss to call particular attention to a few items, but this is done without any disparagement to other papers and these are mentioned simply because they contained something new. Perhaps the most important single item was the discovery that the virus of encephalitis of horses, at least one strain of it, was transmissible to man, and from Massachusetts we had a report from Dr. Feemster, of the State Department of Public Health, of seven human cases directly attributable to the virus from horses. The prevalence of encephalitis in horses in many parts of the country makes this of great importance. Notable also was the forthcoming new edition

of *Standard Methods for Milk Analysis*, which was discussed by Professor Breed at a special milk meeting on Friday.

Everyone knew that the meeting would be charged with intense interest over the National Health Conference held in Washington in July, at which the report and recommendations of the Interdepartmental Committee to coördinate health and welfare activities was made and discussed. A special session on the Public Health Aspects of Medical Care was held at which we were honored by the presence of Dr. Irvin Abell, President of the American Medical Association, who gave a paper explaining the standpoint of the medical profession. This meeting was an indication of the intense interest of our Association in the increase in public health consciousness which has been going on in professional bodies as well as among the public. At the meeting of the Governing Council this took the form of a resolution endorsing in general the recommendations made at the National Health Conference. The Association pledged itself to use all its resources and influence in aiding the governmental agencies in accomplishing these health objectives, and also instructed the Executive Board to appoint a committee of seven Fellows of the Association to coöperate during the coming year with the Interdepartmental Committee, the American Medical Association, the American Dental Association, the Conference of State and Provincial Health Officers, and other agencies, in putting these principles into effect. While we may discount some of the perfervid expressions of opinion on this action, there can be no doubt concerning its far-reaching importance.

On Thursday the Annual Banquet was held in the great Arena of the Auditorium, which on the floor and in the galleries can seat 15,000 people. At the Banquet there were more than 700 persons. Especial awards were announced, including the Health Conservation Contests Awards, following which a remarkable musical entertainment was given, featuring particularly the Indians from the Haskell Institute at Lawrence, Kans., and a Negro choir of some 80 members. One rarely hears more beautiful music than this choir produced.

We were particularly fortunate in having a large number of members and visitors from other countries, the Hawaiian Islands, Alaska, Canada, Puerto Rico, Mexico, and Cuba. Especially gratifying was the large number of our Canadian cousins, and among them we had the honor of entertaining Dr. A. Grant Fleming, Dean of the Faculty of Medicine of McGill University, Dr. John J. Heagerty, of the Department of Pensions and Public Health, Ottawa, and Dr. Adelarde Groulx, the Health Officer of Montreal, who has succeeded Dr. S. Boucher, who added so much to our meetings in the past. Our Canadian membership contributed not only to our pleasure but gave us a number of valuable scientific papers. From Cuba came General Domingo F. Ramos, formerly the Director of Health of that Island, and from Puerto Rico, Dr. Oscar Costa-Mandry. From Mexico we had Dr. L. Andreu Almazan, the Director of Health of that country, and seven of his staff. It was a great pleasure to welcome him, both officially and personally, to this, the first meeting of our Association which he has attended.

The hospitality of Kansas City is always notable. To Dr. Edwin H. Schorer, the genial Director of Health, without question the most efficient health officer Kansas City has ever had, everyone who attended the meeting is under a debt of gratitude. He was ubiquitous, always at the right spot at the right moment. Among the most delightful memories is the reception which he gave at his own residence.

At the last General Session we passed appropriate resolutions recognizing our reception by the officials of Kansas City and Kansas City in general, but we wish here once again to renew these expressions in public. The meeting was a great success from every standpoint, and we owe a debt of gratitude to our hosts.

EDWARD S. GODFREY, JR.

EDWARD Settle Godfrey, Jr., M.D., President-Elect, is a Western product. The second son of the late Brigadier-General Edward S. Godfrey, he was born, in 1878, at Fort Yates, N. D., then a small army post surrounded by the Standing Rock Indian Reservation. From the army post schools, in which his early education was begun, he finally reached Rutgers Preparatory School and the University of Virginia, from which he was graduated in medicine in 1900, interning for two years at the Germantown Hospital, Philadelphia.

His medical practice was begun at Bisbee, Ariz., a mining camp, site of the famous Copper Queen and Calumet and Arizona Mines. (Most of his friends, at one time or another, have been entertained by his stories of the mining camp days.) He practised later in Phoenix, Ariz. In 1908 he was appointed Superintendent of Public Health for the Territory of Arizona. In 1912 he was appointed school medical examiner for Phoenix public schools, and in 1914 City Health Officer.

Edward S. Godfrey, Jr., M.D.

In 1916 Dr. Godfrey went to the Illinois State Board of Health as epidemiologist, later becoming chief of the Bureau of Communicable Diseases. In 1917 he continued his Eastern migration, going to the New York State Department of Health, then being reorganized and expanded under the leadership of the late Dr. Hermann M. Biggs. Later he was director of the Division of Communicable Diseases for eleven years, becoming Assistant Commissioner for Local Health Administration in 1931 and, in 1936, following Dr. Parran's resignation to become Surgeon-General, Dr. Godfrey was appointed by Governor Lehman as State Commissioner of Health.

Dr. Godfrey has been a member of the Association since 1910, and a Fellow of the Association since 1931. The same inquiring attitude and "healthy skepticism" which made him an outstanding epidemiologist has contributed to the value of his service, over a long period, as an active member and Fellow in the Association. As was said by the retiring president when Dr. Godfrey was elected, it was most appropriate that he should have been elected in Missouri, since one of his best known characteristics was his insistence on being "shown."

Dr. Godfrey was one of the founders of the Epidemiology Section of the A.P.H.A. and of the American Epidemiological Society. He was chairman of the former in 1930 and president of the latter 1933-1934. For several years he was Clinical Professor of Epidemiology in the College of Physicians and Surgeons, Columbia University. He has written extensively on subjects relating to health, his best known writings being in the field of epidemiology. His continual seeking after the practical application of epidemiological knowledge is perhaps best exemplified by his paper on the epidemiology of diphtheria, which appeared in the *Journal* in March, 1932.

JOHN SHAW BILLINGS

Born April 12, 1838

FOR the second time this year we commemorate the 100th anniversary of the birth of a great medical man of our United States Army, this time John Shaw Billings, who was born April 12, 1838. Some 34 of his 75 years of life were passed in the active service of the U. S. Army Medical Corps. Much could be said of his military experience and services during the Civil War. Upon his appointment as First Lieutenant and Assistant Surgeon in 1862 he was put in charge of the Clifflburne General Hospital in Washington, which he found in a dreadful condition with "no drainage whatever, no sinks, no water within half a mile," and very inadequate facilities, so that his very first service led him to the study and practice of preventive medicine and hygiene in which he was interested throughout his life.

However, his fame rests on his accomplishments in Washington, where he was ordered in August, 1864. In 1879, Congress created a National Board of Health under the threat of an epidemic of yellow fever, and Dr. Billings was made Vice-President. In 1880, he was made President of the American Public Health Association. His acumen was shown about this time when he said, in speaking of yellow fever, "The belief that disease ever spontaneously originates from combinations of filth, heat, moisture, and the presence of unprotected persons, is an exercise of pure faith with which science has nothing to do at present. . . ." Dr. Billings was one of the first men in this country to lay stress on vital statistics, and he always took a keen interest in the censuses of the United States. His first extensive report on vital and medical statistics was in connection with the Census of 1880, and these reports were continued in 1890, 1900, and 1910.

Dr. Billings took a great interest in the Army Medical Museum, which is now the largest institution of its kind in America and one of the greatest in the world. In December, 1883, the Museum and the Library were consolidated, with Dr. Billings in charge. His reputation, however, has been largely founded on the Surgeon General's Library and its *Index Catalogue*.¹ At the time he took charge, the Library contained 2,253 volumes and the first printed catalogue in 1865 was a little pamphlet of 31 leaves. It has now grown to 50 ponderous royal octavo volumes of the *Index Catalogue*, which Osler called "Billings's float down to posterity." It is said of the *Index Catalogue* that it marks an epoch in the development and improvement of medical literature, particularly in the United States, but it is recognized all over the world as one of the great pieces of bibliography. Indeed, Professor William Bullock, in 1935, said, "Among

catalogues, the Surgeon General's is regarded by the authorities at the British Museum as the greatest ever achieved." In 1879, Dr. Billings established the *Index Medicus*, another "monumental piece of medical bibliography"—merged in 1927 with the *Quarterly Cumulative Index*. It is not strange that he is generally considered the greatest medical bibliographer in the history of medicine.

Dr. Billings is known not only as a great bibliophile and bibliographer but as a librarian. After his retirement from the Army in 1895, he was asked to take charge of the consolidated Astor and Lenox libraries of New York with the Tilden Trust. This is one of the notable libraries of the country and advanced greatly in its usefulness to the public under the administration of Dr. Billings. The present Director of the New York Public Library says of him, "that in the field of librarianship he holds as high a rank as he did in the fields of medicine, of engineering, of statistics."

Dr. Billings held a number of positions, among which was Director of the Hygienic Laboratory of the University of Pennsylvania. He planned the original buildings of the Hospital of Johns Hopkins, where he is regarded as one of the "founding fathers of both the Hospital and the Medical School." Dr. Billings's papers on Medical Education and History of Medicine are especially noteworthy. He gave a course of lectures on the latter subject at Johns Hopkins in the autumn of 1877.

NOTE: The Johns Hopkins Medical Society and the Johns Hopkins Medical History Club held a joint meeting April 12, 1938, to commemorate the 100th anniversary of the birth of Dr. Billings. The Institute of the History of Medicine has issued a Memorial Number, many of the articles of which are found also in the *Bulletin of the Johns Hopkins Hospital* for April, 1938. These are illustrated with many photographs of Dr. Billings.

RAW OR PASTEURIZED MILK?

IN this country everyone who has studied the question even a little is sure of the nutritive value of milk and of its value as a supplementary diet, but even so, strong supporting evidence is welcome.

In England factors led to the formation of a Milk Nutrition Committee.¹ Just before this the Milk-in-Schools Scheme had been set up and afforded an opportunity for a scientific study on its effects on the growth and health of the children participating. It is true that several other such studies had been reported from 1928 to 1930. Research was begun in February, 1935, and ran through the entire school year in each of five areas, covering in all 8,435 children divided into four groups: 2,000 for control, 2,000 on $\frac{1}{3}$ pint of pasteurized milk, 2,000 on $\frac{2}{3}$ pint of pasteurized milk, and 2,000 on $\frac{2}{3}$ pint of raw milk, as a supplementary diet. The study ended in July, 1936. The children were fed a diet to which milk was compared with biscuit, also as a supplementary diet, and were studied as to increase in height and weight after having been assessed clinically as to their general condition. They were also divided as to sex and into three age groups. "Of the 6 comparisons of the average gains in height of these groups over the groups with biscuits, 2 favour raw milk (boys 5-7, girls 11-14), and 4 favour pasteurised (boys 8-10 and 11-14, girls 5-7 and 8-10); of the corresponding comparisons of weight, 4 favour raw milk (boys 5-7 and 8-10, girls 8-10 and 11-14) and 2 favour pasteurised (boys 11-14, girls 5-7).

The only age group in which the two sexes give consistent differences is 8-10 years, in which the increases in height were less on raw than on pasteurised milk and the increases in weight were greater on raw milk."

It is pointed out that in this study the general quantitative response to the milk supplement was not so great as was reported in previous experiments, probably because the amount of milk was smaller and possibly also because of improvement in the average diet of the working class homes during the past 8 years or so. The condition of the study did not allow of any exercise over the control of the home diet consumed by the children or to evaluate it qualitatively or quantitatively.

The general results are in favor of milk as a supplement, even in the smaller amounts. "Comparisons of the growth increments in three different age groups, 5-7 years, 8-10 years, and 11-14 years, show that at each age children with $\frac{1}{3}$ pint of milk gained more in weight than those with biscuits, and probably—but rather less consistently—gained more in height."

Most interesting is the fact that examination of the groups clinically assessed as: "(1) good or excellent, (2) satisfactory or normal, (3) poor or bad, leads to the conclusion that, on the whole, children of each clinical grade with milk supplements showed higher rates of growth than children in the corresponding clinical grades with the biscuit supplement."

As we have said, there does not seem to be any room for argument as to the value of good milk in the diet. There are still those who question the comparative value of pasteurized milk as against raw, so that the following conclusion is of especial interest. "Whether comparisons be made of the increments of growth in the total of children or in sub-division by age, area, and clinical assessment, no consistent difference is apparent in these increments between children whose supplement was $\frac{2}{3}$ pint of pasteurized milk and the children whose supplement was $\frac{2}{3}$ pint of raw milk." An experiment done on such a large scale and under the conditions pertaining in this one should settle the question of the value of raw as compared with pasteurized milk in feeding children, especially as it confirmed the laboratory tests carried out by the same institution.¹

The whole report is full of interesting questions to those in the field of nutrition generally or to school children and their physical welfare. It must be read and studied to be fully appreciated.

Get Them into Courses—We have not done so much in getting groups to attend courses of lectures, single talks, or discussions.

A paid course, at moderate prices, with more or less of reading, study, and consultation as "accessories," would be one step toward securing a much needed nucleus of informed local leaders. For several years in Massachusetts, the university extension courses of the State Department of Education, Boston, Mass., has given a series of lectures in non-technical language called "Keeping Mentally Fit." A fee is charged for auditors; a larger fee for credit students. The nature of the courses and the groups likely to be interested, are carefully described in the announcement folder.

For Prospective Fathers—Reports Maternity Center Association, 1 E. 57th St., New York, N. Y.:

Last year the Maternity Center Association announced a series of classes for prospective fathers to teach them the physiology of pregnancy; how to choose good medical, hospital, and nursing care for their wives; how to help their wives keep fit; how to care for the baby; and how to help to fit the baby into the home without needless confusion.

The association was besieged by men eager to take the course. After they had completed the 5 lessons and several practice periods in bathing, dressing, watering,

bubbling, and diapering the demonstration doll, they all agreed that the course had helped them to approach paternity with a feeling of preparedness.

The association has received a number of requests for the outline of the material presented to this group of pioneer students in expectant paternity. This syllabus has been prepared in response to these requests. Suggestions for its improvement will be greatly appreciated.

In response the association offers a "Syllabus: Classes for Prospective Fathers." 15 cents. This includes the announcement which introduced the idea to newspaper readers. Outlines for 4 lessons are given.

"A Talk for Prospective Fathers" is based on the outline for the first of the 4 lessons. 10 cents.

The following is the suggested substance of a talk by a physician to men whose wives are about to become mothers. It gives in outline form certain information about childbirth and suggests topics for discussion. The form of the talk may have to be varied according to the size and background of the group. But the aim is to describe briefly the process of generation, including anatomy and physiology, the signs and symptoms of pregnancy, the course of labor, the occurrence of various common disturbances and diseases.

There are many general facts which should be known to the husband so that he may be able to comprehend more effectively his responsibilities in this all-important function. This knowledge should contribute to the happiness and welfare of both partners. In all of this, the necessity for early and adequate medical care is to be stressed and the father urged to participate in providing good care for his wife.

The speaker may modify or add to the material in this outline as seems best in his judgment. Prospective fathers will better understand the process of generation and birth if the descriptions of the organs, fertilization, the course of labor, and other features are illustrated with simple blackboard drawings, or with the aid of models, charts, etc. Simplicity should prevail in presenting the subject; there is no need for elaboration of details, and discussion of treatment should be avoided.

The talk seems to emphasize that the course is a rather stiff one. It would

seem wise for Maternity Center Association to submit more suggestions as to the methods of handling a group of fathers.

A Different Report—Under the quoted headings appeared the paragraphs below, and others.

"Well, *What Have Ye Done?*"—"Well, what have ye done in the two years ye have been galavantin' around this country?" Mrs. Smith asked when I told her the Health Department had a birthday," remarked Miss Hassels, the nurse, at the regular staff meeting in July. . . .

"That's a good question, what have we done?" repeated the director, leaning back in his swivel and looking around at his staff. There were Dr. P. R. Lynch, the dentist; E. C. Knight, Sanitary Engineer; Miss Hilda Cabaniss, Osceola County Nurse; Margaret Wilson, Clerk in Reed City office; Miss Anna Hassels, Mecosta County Nurse; and Velma Allen, Big Rapids Clerk. . . .

A Matter of Life and Death—"I noticed that birth registrations are increasing so far this year," remarked Mrs. Allen. "Last year the birth rate dropped considerably. Death certificates coming in from local registrars show a decline, even as compared with the number recorded in 1937, which was lower than in 1936."

"Yes, I noticed that, too," said the director. "In the first 6 months of this year, there were 31 more births than in the same period of 1937 and there were 36 less deaths."

"What does this mean? Figures do not lie. By inspecting them at frequent intervals we can determine whether we have made progress or whether we have merely marked time. The recording of births and deaths makes up the balance sheet of our population. From these records the health officer may draw knowledge to be applied in future public health programs."

Mary Runs Wild—"Here is a letter from a doctor up in Marion who complains that Mary Smith is running wild with untreated gonorrhea. The girl is only 16," Dr. Igloe added.

"We have another case in a 14 year old girl. She is also pregnant," remarked Miss Cabaniss.

"It seems that venereal disease is a disease of youth—and that is what the records really show," remarked the Director, "of 22 cases of gonorrhea recently reported, 17 were under 30 years. Of 9 cases of syphilis reported, 6 were under 30 years of age."

The above are selected from "After Two Years: The Story of the Mecosta-Osceola Health Department—1936-38." The Central Office for the two counties is at Big Rapids, Mich. Although the report does not indicate the state. Director M. C. Igloe, M.D., has a dentist and sanitary inspector, and a clerk and nurse in each county.

"Contents" has two parts. "The Story" in 10 chapters is text; "The Facts" are 10 statistical and factual tables. Mimeographed on letter size paper, heavy cover, spiral binding, yellow paper for the statistics.

Another year it is hoped that chapters 9 and 10 of "The Facts" will be made chapters 1 and 2 where they will not be lost to those not interested in the statistics. These chapters are 3 pages of "Services Rendered," and a page organization diagram.

Don't Unbalance the Diet—An editorial, "Fifty-Fifty," in *Editor and Publisher* (Oct. 22, 1938) discusses a recent prophecy that soon the newspaper will be half text and half pictures.

A picture may be worth 10,000 words, but not every picture is. Few in fact are. A picture, or a series of pictures, can tell some stories completely; they can often complement a word story which needs visualization for completeness. Many stories would be the better for illustration—but a picture alone cannot convey to readers the balanced diet of information necessary for the operation of a democracy. . . .

We have never found an interesting story hard to read because it was set in a gray-black column of type. We don't object to length when length means information—and the popularity of the mastodon novels like *Gone With the Wind* indicates no public aversion to mere length or solid gray pages.

If newspaper words paint pictures, as they should, there'll be no need for making the photographer do all the work. Pictures have their place—one of increasing importance—but it is not at the head of the parade. . . .

Says Dr. Iago Galdston, sender of the clipping:

It is worth noting that we see with the brain and not alone with our eyes. The visual message should therefore be for the brain through the eye. Too many stop at the eye level! Again when thought is given to the message for the brain, text is frequently found to be the better vehicle.

Need there be a moral? At least we guard against any method or technic of presentation running away with our health education. And what we have to say to secure the result we are after calls for first consideration. Then we select and balance the forms of presentation.

A Gay Health Play for Adults—Written for a "father-mother-daughter" banquet it includes no fairies, and its solemnity is mockery. Built around the alleged health habits of four leading citizens, in use elsewhere the idea would need adaptation to local people.

It is "The Health Court," by M. C. Pearson. *Womans Press*, 600 Lexington Ave., New York, N. Y., Oct., 1938. 20 cents. A sample:

The Bailiff places Mrs. Jones before the Judge:

Prisoner Jones is accused of sleeping less than 9 hours per night. Hither and yon she goes, to board meetings, to clubs, to committee meetings, keeping late hours and arising early each morning in spite of it. Sometimes she is known to go to bed on time but to lie awake and think! (He reads slowly and impressively.)

Judge (sadly, shaking his head): Lie awake and think! Does the prisoner not know that 9 hours' sleep are absolutely essential if she wants to be president of the board and a member of this and a member of that? Prisoner, what have you to say for yourself?

(The prisoner answers, but no matter what she says, the play goes on as written.)

Judge (turning to the Jury): Gentlemen of the Jury?

Jury (rising): Guilty, Your Honor. (They sit.)

Judge: Prisoner Jones, I sentence you to one week at home without any outside cares or diversions, responsibilities or excitements, committee meetings or conferences. You shall have a 2 hour nap every afternoon and abso-

lutely 9 hours' sleep every night thereafter. Next!

(Prisoner Jones goes back to her seat on the stage as the next prisoner comes up.)

"Preventive" Or Not "Preventive"?—Here is an inquiry which comes from E. Louise Williams, Librarian, State Board of Health, Jackson, Miss.:

I would like to have your opinion with regard to the use of the word "preventive" in connection with the following:

preventive health services
preventive health examinations.

"Preventive" appears to modify the word "health" in these expressions, and in a literal sense seems to be inaccurate. To the laity who read such expressions, there is likelihood of only the first two-thirds of the thought registering, and from a "selling" standpoint the psychology seems poor. I have stumbled across these expressions several times recently and before I consider their adoption, would like to have the benefit of your opinion.

What Would You Have Said?—Will someone tell me what advice and information might well have been sent in reply to the letter quoted below?

Your address has been referred to me as a possible source of aid with publicity. We are about to put on a campaign and I feel this small city that has had our organization for 25 years needs some rather good publicity. They have had the same work for so many years.

MAGAZINE ARTICLES

"Hostess." *American Magazine*, 250 Park Ave., New York, N. Y. Aug., 1938. 25 cents. One phase of the problem of caring for some of the needs of those who reach hospitals, clinics, etc., as patients or visitors. This is a self-supporting "Hospitality Shop."

"The Fight on 'Polio,'" by Dr. W. R. Ramsey. *Farmer's Wife Magazine*, St. Paul, Minn. Sept., 1938. 10 cents. Some late developments.

"X Ray marks the spot," by H. Ripperger. *Good Housekeeping*, 57th and 8th Ave., New York, N. Y. Oct.,

1938. 25 cents. "The case against tb." well stated. Also: "Reduce and Like It," by K. Fisher; "Avoid Pitfalls in the Reducing Game," by Dr. W. H. Eddy. "Treatment of obesity is the province of the physician." As to the menus: "They may be of service to you and your physician."

"Animal Experimentation." Is it essential to the progress of medicine? *Life*, 330 E. 22d St., Chicago, Ill. Oct. 24, 1938. 10 cents.

"Movie of the Week: The Citadel." *Life*. Nov., 1938.

"A Medical Student Becomes a Doctor: The Life of an Intern," by Dr. Morris Fishbein. 4 picture pages. *Look*, Des Moines, Ia. Oct. 25, 1938. 10 cents.

"Population Problems," by H. Ward. *New Republic*, 40 E. 49th St., New York, N. Y. Aug. 17, 1938. 15 cents. "The net impression . . . is that if we can learn to provide adequately for our present . . . people, we will not need to worry about the bogey of excess numbers in the future."

"The Falling Birth-Rate." *Social Welfare*, 37 Bloor St., West, Toronto, 5, Ontario. Sept., 1938. 25 cents. "The falling birth-rate need not worry us. It is exactly what any sane person would expect."

"By Six-to-One in California," by P. K. Brown, M.D. *Survey Graphic*, 112 E. 19th St., New York, N. Y. Nov., 1938. 30 cents. State supreme court action on group medicine. Also: "We Can Banish Gonorrhea," by J. B. Clark, M.D. "The battle ahead is going to be a long and hard one."

NEW

Health Education In Kansas, Kansas Tb. and Health Assn., Topeka..

Your Health, Health Dept., Newton, Mass., now printed. An ornamented heading on the first of the 4 pages, a tinted background, different for each

issue. Will be mailed to health officers upon request.

Here's Health! weekly mimeographed bulletin of State Board of Health, Dover, Del., comes with a metal staple to be removed before reading—not so good for appearance or for the patience of receiver. Probably in the state at least, it would carry nicely without fastener. Outside of the state use a sticker, or a bit of transparent Scotch tape? Then run in addressing machine so that the fold is at the top. See "How the House Organ Is Addressed" elsewhere in this issue.

Nassau Health, Nassau County Dept. of Health, Mineola, N. Y. Mimeographed, 4 letter-size pages.

Channels, Social Work Publicity Council, 130 E. 22d St., New York, N. Y., is the new printed periodical, successor to the mimeographed *News Bulletin*. It is an effective combination of color, paper, and typography, developed largely through the advisory services of Curtis E. Lakeman. Mr. Lakeman was long known in connection with health agencies—New York State and New York City Health Departments, and the formative years of the American Society for the Control of Cancer—in which he had much to do with health education or its general supervision. In the first issue Mary Swain Routzahn, under "But Not One Cent for Publicity," reviews current criticism of governmental publicity, and raises questions, some of which have a bearing on city and state health department health education, particularly that which calls attention to the activities and services of the departments.

WANTED

Material for a talk to high school groups on "Why a County Health Department" will be welcomed by S. S. Burner, M.D., District Health Unit, Owensville, Mo.

BOOKS AND REPORTS

Public Health and Medical Licensure in the State of Mississippi, 1798-1937—By *Felix J. Underwood, M.D., and R. N. Whitfield, M.D. Jackson, Miss.: State Board of Health, 1938. 175 pp.*

The book deals with the development of public health work in Mississippi from 1799, when the Legislative Assembly of the Territory of Mississippi passed an act "to provide as far as possible against the fatal calamities of contagious diseases," to 1937. The first law requiring a medical license in Mississippi was approved February 12, 1819.

The history of public health in Mississippi may be divided into three periods. The first begins with the formation of the Mississippi Territory in 1798 and extends to the organization of the Mississippi State Board of Health in 1877. During that period a health department for the City of Natchez was established by law in 1818, in which year Mississippi became a state. It provided for sewage disposal; regulation of the sale of damaged or unsafe commodities; a report by the attending physician giving the age of deceased persons and the cause of death; and the appointment of a skillful physician as health officer. Following that, other state laws were enacted referable to the sale of unwholesome food; the establishing of a smallpox vaccine depot in Jackson in 1846; the empowering of towns to pass health regulations; and legislation creating boards of health in Hancock, Harrison, and Jackson Counties.

The second period extends from 1877 to 1910, in which the significant de-

velopment was the organization of a State Board of Health in 1877. That body was organized in such a way as to become a part of the Mississippi State Medical Association. The same plan of organization exists today except that a dentist has been added.

The third period extends from 1910 to 1937. It began in 1910 with the appointment of Dr. W. S. Leathers as the Director of Public Health for the Mississippi State Board of Health in charge of organization and administration of public health activities. As a result of the stimulation of interest on the part of the public by the workers connected with the hookworm campaign conducted by the State Board of Health in coöperation with the Rockefeller Sanitary Commission, the first full-time county health department was organized in 1915. Other important developments were the organization of a bacteriological laboratory and the office of State Sanitary Inspector which later became the Division of Sanitary Engineering. A Bureau of Vital statistics was established in 1912 with the result that the state was admitted to the U. S. Death Registration Area in 1919 and to the U. S. Birth Registration Area in 1921. Biological products were purchased and distributed to physicians and health officers. Morbidity reporting was instituted in 1913. In 1917 Dr. Leathers was made Executive Officer of the Mississippi State Board of Health and was succeeded in 1924 by Dr. Felix J. Underwood.

Coöperation with other health agencies has been an important factor in the development of the organization. The Rockefeller Sanitary Commission

and the International Health Division of the Rockefeller Foundation, the U. S. Public Health Service, the American Red Cross, the Commonwealth Fund, and the Rosenwald Fund have all aided materially since 1910.

Important research and field investigations relative to yellow fever, pellagra, malaria, typhoid fever, hookworm, and epidemic encephalitis have been conducted which have contributed to our knowledge of these diseases and have aided in their control.

The present organization includes the essential administrative units of a modern health department serving a southern state. It has kept pace with the advances in the field of preventive medicine and has developed its local full-time service to the point where in 1937 there were 33 counties with full-time public health departments serving 50 per cent of the population and covering 40 per cent of the state.

The book contains excerpts from original acts of the Legislature and addresses of members of the medical profession relative to public health matters. Included are charts, maps, and biographical facts relating to those who have been instrumental in the development of public health work in Mississippi since 1877.

ALVIN E. KELLER

The Hospital Head Nurse—By Mary Marvin Wayland, A.M., R.N. New York: Macmillan, 1938. 388 pp. Price, \$3.50.

Those who are charged with the responsibility for hospital management have a true realization of the all important part played by the head nurse. The author defines the purpose of this book as a desire to help head nurses to a better understanding of their responsibilities to the hospital and to the school of nursing. It meets the great need of those who are particularly concerned with the efficient conduct of

the executive aspects of ward nursing and the training of nursing personnel.

Twenty-two chapters and appendices are devoted to pointing out the varied duties and responsibilities of head nurses. Seven of these, in very readable form, are devoted to a presentation of the nurse's responsibility as hostess, nursing expert, practical sanitarian, housekeeper, steward, economist, a junior executive, and as a teacher of both patient and staff. The part she should play in the school of nursing program is also thoroughly defined.

The material is authentic, well outlined, with good summaries, and rich in biographical references.

There is a marked relation between the efficiency of the head nurse and the good care of the patient, and this book can be of invaluable aid in the training for more efficient management, and in the furtherance of nursing education.

CHARLES F. WILINSKI

Science in Our Lives—By Benjamin C. Gruenberg and Samuel P. Unzicker. Yonkers, N. Y.: World Book Co., 1938. 750 pp. Price, \$1.76.

During the last twenty years, there has been a great deal of discussion in secondary school circles as to the need of organization of courses in "general science." The implication is that it is possible to give high school students a single course that will develop for them a concept of the most important phases in such sciences as chemistry, physics, biology, and hygiene. This is in direct contrast to the older procedure of giving separate courses in physics and in chemistry, and, in later years, in biology. The high schools in a considerable number of communities now offer such a combined course.

This text is an effort to provide reading material, problems, and activities which shall "offer opportunity for practical training in scientific thinking in everyday situations." These activi-

ties include experiments, demonstrations, and investigation. An effort is made to appeal to the varying interests of the young people concerned.

The text is divided into two parts: Part I including four units on air, water, fire, and earth; and Part II having four units, the first of which "Controlling the World" deals with work, machines and tools, power and motors, the second dealing with electricity, the third with the living machine, and factors like foods, environment, reproduction, heredity, and mental attitudes which affect the conditions of that machine, and fourth a discussion of the special senses.

Each chapter has at its end a summary of the chapter, a group of questions on the material covered by the chapter, and a group of problems for the class to work on in an effort to bring concentrated thought upon the more important factors discussed.

CHARLES H. KEENE

Posture and Exercise for Young Children—By Dr. John Gibbens. London: National Association of Maternity and Child Welfare Centers and for the Prevention of Infant Mortality (Carnegie House, 117 Piccadilly, W. 1), 1938. 23 pp. Price, \$.50.

This helpful and attractive pamphlet presents a clear picture of what may be accomplished in developing good posture in young children. Following a general description of what good posture means and its effects upon health, there is given a series of exercises as a part of play designed to bring all the skeletal muscles into activity. These exercises are illustrated with charming silhouettes of young children in action. The author warns that "formal exercises and fixed gymnastics are bad for young children, for they do away with wit and humour and imagination, without which the world would be a poor place." The pam-

phlet is well written and should prove helpful to those engaged in infant and preschool work.

RICHARD A. BOLT

Health, Hygiene and Hooey—By W. W. Bauer, M.D. New York: Bobbs-Merrill, 1938. 322 pp. Price, \$2.50.

This book, written for the layman, is different. The author calls attention to the fact that so much interest has been aroused in health that there is a vast amount of both information and misinformation (entirely too much of the latter) peddled by all sorts and kinds of people. It is important to be able to distinguish between authentic sources and those that are not, therefore, instead of naming names, as he expresses it, he devotes his efforts to general principles. He says, "The best safeguard against exploitation is a knowledge of principles. Individual exploiters come and go; nostrums rise, flourish, and vanish; quackery is different every day and yet, fundamentally, the same. A person who understands the characteristics of charlatanism will not be fooled by the individual exploiter." The general argument is summed up in his last chapter, "Common Sense, Preferred," and his last words warn the health seeker that his best security will be found in "Common Sense, Preferred, and Skepticism, Unlimited."

The author has a gift for striking titles, such as "Swivel-Chair Hygiene," "Dispelling Dietary Dilemmas," "A Fake for Every Ache," "Soft Soap and Skin Games," etc. We particularly recommend Chapter XIV "Who Pays the Piper." In addition to formulating striking titles, he also has a humorously impressive way of putting facts. For example, in speaking of mascara, he says, "Making up the eyelashes is a safe procedure if only mascara is employed. This formerly put the lady at

a disadvantage, because tears played havoc with it. Now all that is changed with the advent of waterproof mascara, which allows a lady to weep and still be lovely." The ordinary materials of everyday make-up are called "war paint." "... hope springs eternal in the baldest heads, and the shining pink cranium is always good for a rub of something or other which raises hope if not hair."

There is a long appendix called "They're Telling You!!" in which are given the principal governmental sources from which one may get correct information on health, also the voluntary societies, beginning, of course with the A.P.H.A.—"the basic fundamental organization of technical workers in public health, including doctors, nurses, laboratory and research technicians, engineers, sanitary officers, statisticians, and health educators." The author does not believe that a book list should be given in a work of this kind since books come and go and such lists should be kept up-to-date to be of real value. However, he gives 22 books now on the market which may be consulted, and 5 health magazines.

The book is interestingly written and will hold the attention of readers. It goes well with "The Traffic in Health" and "Poisons, Potions, Profits." It is accurate and can be recommended without any reservation. We wish for it a wide circulation.

MAZÏCK P. RAVENEL

In the Name of Common Sense: Worry and Its Control—By *Matthew N. Chappell*. New York: Macmillan, 1938. 192 pp. Price, \$1.75.

This book was written "for and about normal people—people who can lay the foundations of their own emotional discomforts, nurture them to inconvenient intensity, and learn with ease to control them." The author believes that worry, which is so prevalent

an activity in this era of great insecurity, is an expensive luxury which no individual can afford, and the book is offered as a guide for the intelligent layman who has inadvertently become an accomplished worrier and who wishes to eliminate this drain on his energies.

Worry, or the undue preoccupation with painful thoughts, is regarded as a psychological habit which has been learned and gradually developed through persistent practice. The really proficient worrier, as a result of his emotionally charged thinking, gradually acquires a whole series of alarming symptoms, which may include anxiety and fear, fatigue, indigestion, decrease in sexual interest, constipation, insomnia, a variety of pains and aches, excessive irritability, and marital unhappiness. A chapter on each of these subjects is offered "to supply 'insight,' to explain the acquisition of discomforts; their real significance, if any; and how they may be controlled."

The book is based on extensive experience, much of which has been in collaboration with physicians, in the successful adjustment of patients through psychological re-training. It is written in a vigorous and humorous style, which will hold the reader's interest, and for the group to which it is addressed, it should be of great aid in understanding and overcoming their difficulties.

CLARA BASSETT

Industrial Hygiene—A Handbook of Hygiene and Toxicology for Engineers and Plant Managers—By *Laurence B. Chenoweth, M.D., and Willard Machle, M.D., with Foreword by Herman Schneider, Sc.D., LL.D.* New York: F. S. Crofts & Co., 1938. 235 pp. Price, \$2.00.

This is essentially a brief general coverage, by a community and school hygienist and an industrial toxicologist, both of Cincinnati. The first 7 chapters (by Dr. Chenoweth) comprise a

historical introduction (7 pp.); workmen's compensation (7 pp.); industrial accidents (14 pp.); fatigue (6 pp.); physical factors in industrial hygiene (11 pp.); health service in industry (10 pp.)—with somewhat disproportionate space given to *locomotor ataxia*; and first-aid treatment of injuries (27 pp. plus appendix of 20 pp.)—well rendered, with many illustrations. Rather too much space is given to snake bite and far too little to tuberculosis for industrial hygiene purposes.

The succeeding 8 chapters (119 pp.) by Dr. Machle are chiefly a laboratory approach—brief, well rendered, and fairly comprehensive—on occupational intoxication; chemical burns; oxygen deficiency and asphyxia; dust diseases; respirators, etc.; occupational affections of the skin; industrial neuroses and malingering; and miscellaneous occupational affections. The author shows an original and interesting approach to the poison question. Some of the definitions within which he confines himself seem too restricted to the reviewer.

Dangerous trades and callings are, in general, omitted. The great majority of the 104 illustrations pertain to first-aid procedures. An adequate Index accompanies and the book is well printed and bound.

No bibliography is included, but a few references are made. Necessarily many omissions occur in a limited volume devoted to such a broad subject.

There are several comparable and more extensive works in this same field with which the engineer and plant manager should also stock his library.

EMERY R. HAYHURST

A Historical Chronology of Tuberculosis—By Richard M. Burke, M.D. Springfield, Ill.: Thomas, 1938. 84 pp. Price, \$1.50.

This book is divided into four periods, the Ancient (5000 B.C.—1600

A.D.), the Pre-Modern (1600—1800), the Modern, Part One (1800—1881), and the Modern, Part Two (1882—19—). The chronology is useful and as far as the reviewer has been able to check it, correct. One is surprised to find such things mentioned as the invention of gunpowder in 1330, the voyage of Magellan in 1519, the invention of the power loom in 1785, etc., and one finds it hard to see what these have to do with the history of tuberculosis. The author explains that he has included certain happenings which formed a part of the background upon which the pattern of tuberculosis has unfolded, but in spite of this explanation, we cannot see that these events are pertinent to the subject. Certain medical events, like the Black Death in 1348, and the discovery of insulin in 1921, also appear to have no bearing on tuberculosis.

We wish that the author had been a little more exact concerning the London Congress on Tuberculosis in 1901, in which Koch claimed that bovine tuberculosis was not important as a danger to man. He was combated at once at the same Congress with facts which were amplified in 1902, when experiments under way in 1901 were complete.

Altogether, the book is a useful and interesting one. It ends with a chart giving a graphic outline of the development of our knowledge of tuberculosis. The printing and make-up are excellent, and the book can be recommended to all interested in this disease. There is a very good index both of names and subjects. MAZÏCK P. RAVENEL

An Introduction to Medical Statistics—By Hilda M. Woods and William T. Russell. London: P. S. King & Son, Ltd., 1936. 125 pp. Price, \$2.75.

This book was written to meet the needs of young medical students in the

London School of Hygiene and Tropical Medicine. Although small enough to be placed within the pocket, it touches upon the essentials of vital statistics. What is meant by statistical analysis is well expressed and in few words.

Chapter headings include Vital Statistics, Tabulation of Data, Construction of Charts and Graphs, Population, Standardised Death-Rate, Averages, Measures of Dispersion, Correlation, Coefficient of Regression, Life Tables and Sampling.

Pit-falls into which the student often falls are illustrated. Numerous tables

and graphs add to the value of the book.

Statistics is a confusing subject to most medical students. They have difficulty in clarifying within their minds the meaning of statistical constants, such as averages, measures of dispersion, correlation, etc. It is to be regretted, therefore, that this book unnecessarily adds to the confusion when it makes general use of an arbitrary origin in its illustrative computations.

The book can be read from cover to cover in a few hours and the subject of medical statistics will be found far from dull.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

On Sundry Matters—The further preventive medicine is kept from curative, the better the jobs will be done. The time for clinics detached from hospitals is past; clinics in health centers should be discouraged. Rheumatic fever stands next to tuberculosis, pneumonia, and syphilis among the communicable diseases and is the forgotten health problem. Domiciliary medical and nursing care must be developed under non-political auspices. These are random gleanings from a long and provocative paper.

CORWIN, E. H. L. Reorientation in the Public Health and Hospital Organization Patterns of Our Communal Life. New York State J. Med. 38, 20:1320 (Oct. 15), 1938.

Standards of Driving Fitness—In last month's Annotated Bibliography, we learned that with not more than 0.5 parts per 1,000 of alcohol in the blood, one could drive with no more chance of accident than if he had not had a drink. Now we are told that 2 oz. of whiskey or 1 to 1½ qts. of beer, taken on an empty stomach, will give a blood alcohol concentration not in excess of that amount. After a meal double quantities may be taken within the same limits of effect.

HAGGARD, H. W., *et al.* Quantitative Differences in the Effect of Alcoholic Beverages. New Eng. J. Med. 219, 13:466 (Sept. 29), 1938.

Rheumatic Fever Signs—"Growing pains" are not related to rheumatic fever and do not provoke rheumatic carditis. They are usually associated with colds, slight orthopedic deformity, and other conditions that can be discovered and treated by ordinary

methods. If this British doctor's views hold water on this side of the Atlantic, some health educators hereabouts had better look to their teaching material.

HAWKSLEY, J. C. The Incidence and Significance of "Growing Pains" in Children and Adolescents. J. Roy. San. Inst. 1, 13:798 (Oct.), 1938.

Ten Years' Improvement in Tuberculosis Incidence—Percentages of certain Philadelphia high school students reacting to tuberculin declined from 80 in 1927 to 64 in 1937. In girls the decline was greater than in boys. There was no decline in incidence of infection among Negro students. Also, the incidence among Philadelphia high school students remains considerably higher than in many other cities.

HETHERINGTON, H. W., *et al.* The Incidence and Control of Tuberculosis in High School Children. Am. Rev. Tuberc. 38, 4:406 (Oct.), 1938.

Good News (Sanitary)—In 1930, for the first time in United States history, the population living in communities having sewage treatment caught up with the increase in urban population. Since then, the sewage of 6 million additional people has been disposed of by some method better than dilution. During this time the improvement has been qualitative as well as quantitative, for there has been a distinct advance in every phase of the sewage treatment art.

HYDE, C. G. A Decade of Sewage Treatment: 1928-1938. Munic. San. 9, 10:480 (Oct.), 1938.

Urban Birth Rates—Country people who move to the city before

marriage have no more children than city folks. This is true of colored and white people.

KISER, C. V. Birth Rates Among Rural Migrants in Cities. *Milbank Quart.* 16, 4:369 (Oct.), 1938.

Children's Carious Teeth—Although girls have more caries than boys of the same age, their teeth erupt earlier and hence have a longer time to decay. Allowing for this factor, it appears that girls are no more susceptible to dental caries than are boys. The moral is that conclusion jumping is a hazardous indoor sport.

KLEIN, H., and PALMER, C. E. Studies on Dental Caries. *Pub. Health Rep.* 53, 38: 1685 (Sept. 23), 1938.

Outlook for Education in Preventive Medicine—Recounting the growth of facilities for teaching preventive medicine to medical students, the author points to the recently created need for more trained medical health officers than the educational institutions can supply with their still limited training facilities in this field.

LEATHERS, W. S. Preventive Medicine. *J.A.M.A.* 111, 17:1517 (Oct. 22), 1938.

Nutrition and Child Development—Among a group of institutional children, a third were kept on the usual diet, a third were given a pint equivalent of evaporated milk in addition, and the remaining third the same amount of irradiated evaporated milk. As would be expected, the control children on a mediocre diet did not progress as well as those receiving supplementary milk, but those on irradiated milk did no better than those on plain.

MACNAIR, V., and ROBERTS, L. J. Effect of Milk Supplement on the Physical Status of Institutional Children. *Am. J. Dis. Child.* 56, 3:494 (Sept.), 1938.

Air Comfort—Dry-bulb thermometer readings are no index of comfort. Other instruments and indexes that

may be used in determining "effective temperature" are described in this excellent article which has so much significance in these days of super-air-conditioning.

MCCORD, C. P., and WITHERIDGE, W. V. Measurement of Air Conditions. *J.A.M.A.* 111, 18:1647 (Oct. 29), 1938.

Making the Sanatorium Prevent—The evolution of the modern tuberculosis sanatorium and its broadening functions in the control program are excellently presented in this paper which is of especial value to health administrators who should be concerned with the preventive features of the recently recreated nation-wide interest in that disease.

POPE, A. S. The Rôle of the Sanatorium in Tuberculosis Control. *Milbank Quart.* 16, 4:327 (Oct.), 1938.

Eminently Logical—New York City's tuberculosis control program is largely given over to case finding and most of the available services are devoted to the groups where the most good can be accomplished; that is, adults in susceptible racial and economic groups. The rapid roll paper method has proved convenient, inexpensive, and satisfactory.

ROBINS, A. B. Mass Case-Finding. *Am. Rev. Tuberc.* 38, 4:448 (Oct.), 1938.

Clinical Lecture—Proof that good prenatal care pays.

SCHWARTZ, O. H. Antepartum Care. *J.A.M.A.* 111, 16:1460 (Oct. 15), 1938.

Super-Eating—Once accepted as fundamental, that one cannot advantageously consume more food than one obviously needs, the statement is found to be over-simplified in the light of recent research in nutrition. What must be taught now is scientific discrimination in diet.

SHERMAN, H. C. Relation of Nutrition to Optimal Health. *J. Health & Phys. Ed.* 9, 7:406 (Sept.), 1938.

In Praise of Breast Feeding—

It is safe to assume, this British writer assumes, that 20 to 30 per cent of babies are artificially fed from birth, and that not more than a third are fully breast fed through the first 6 months. Mortality and morbidity rates are higher among artificially fed infants. Lactation is good for the mothers, too. How mothers can be induced to nurse their babies is considered at length.

SPENCE, J. C. The Modern Decline of Breast Feeding. *Brit. M. J.* (Oct. 8), 1938, p. 4057.

British Views on Epidemiology

—Droplets do not go around corners with any facility, if at all. That is why the cubicle system works in infectious wards. Scarlet fever nursed in cubicle wards showed no changes in

serologic types, but in multiple bed wards a majority of patients became reinfected with other types often to their disadvantage. Many other avenues for the spread both of respiratory and intestinal infections in these two interesting papers.

STALLYBRASS, C. O., and SMITH, H. G. Changing Views as to the Spread of Infection. *J. Roy. San. Inst.* 1, 13:769 (Oct.), 1938.

Housing Accommodations and Child Bearing—Pointing out the need for quantitative as well as qualitative considerations in housing, the author concludes that private enterprise can hardly be induced to provide housing units suited to a sound population of optimum size.

THOMPSON, W. S. The Effect of Housing Upon Population Growth. *Milbank Quart.* 16, 4:359 (Oct.), 1938.

ASSOCIATION NEWS

RESOLUTIONS PASSED AT KANSAS CITY

CERTAIN of the Resolutions passed at the 67th Annual Meeting in Kansas City are of such timely importance that they are printed below. Other Resolutions will appear in the *Association Year Book*.

It is particularly important that the official text of these Resolutions be read by all persons who are interested in just what the American Public Health Association has approved, especially in view of confused reports in the public press.

THE NATIONAL HEALTH PROGRAM

THE American Public Health Association, ever increasingly conscious of the leadership and competence which have characterized the work of the various federal health agencies, records its unanimous satisfaction in the further evidence of the effective interest of the federal government in the health of the nation, embodied in the recommendations of its Interdepartmental Committee to Coordinate Health and Welfare Activities to the National Health Conference, July 18-20, 1938.

There can be no doubt that large areas of many of our states do not enjoy the benefits of adequate health service. We maintain that without adequate local health organization covering every area of the United States, the delivery of the full benefits of modern public health procedure to all the people in the United States cannot be accomplished. We recognize further the indispensable services which state departments of health are capable of contributing over and above those provided under local governmental units in urban or rural communities.

In recognition of these facts, we endorse the recommendations presented before the National Health Conference by the Technical Committee on Medical Care, which propose the expansion of public health services, including necessary medical, hospital, and nursing care for the period of maternity and childhood in

families unable to obtain adequate care through their own resources.

An appraisal of national health resources reveals the existence of many communities in which hospital facilities are meager or lacking. The inadequacy of institutional facilities presents a handicap to the control of tuberculosis and mental disease, and deprives those requiring care in general hospitals of the full benefits of modern medical treatment. In certain communities adequately supplied with hospitals, economic barriers prevent their full utilization. For large numbers of our population, inadequate income results in inadequate medical and dental care. The concept of the close interrelation of preventive and curative medicine is basic to the modern public health program.

We therefore endorse the recommendations of the Technical Committee to the National Health Conference providing for federal aid to the states for the construction of additional hospital facilities, the provision of essential medical and nursing care, and hospital care as required, to persons unable to support such care from their own resources, and the compensation against wage loss incurred through sickness. In connection with the Technical Committee's recommendation concerning medical care, the Association supports the view that in the initiation and development of the program, wide latitude should be given to the states in the definition of the population to be served and the method of providing medical service.

We pledge the American Public Health Association to use all its professional resources, and such influence as it has earned through sixty-eight years of development and leadership in public health to aid governmental agencies in accomplishing those statesmanlike health objectives.

Furthermore, we offer our coöperation to the governmental agencies which may be charged with the proposed expansion of health services in the United States, and we stand ready to collaborate with other professional and scientific organizations having similar principles and objectives, to the end

that at the earliest possible date in every area under the jurisdiction of the United States the whole population may have the benefit of the best that public health service can bring them.

BE IT RESOLVED that the foregoing declaration expresses the formal and considered opinion of the American Public Health Association and that it shall be published in the *Journal*.

BE IT FURTHER RESOLVED that the Executive Board is hereby instructed to appoint a representative committee of seven Fellows of the Association to coöperate during the coming year with the Interdepartmental Committee of the United States Government, with the American Medical Association, the American Dental Association, the National Organization for Public Health Nursing, the Conference of State and Territorial Health Officers and with other agencies, to the end that these principles may be translated into effective action.

APPRECIATION OF PARTICIPATION

BY DR. IRVIN ABELL

THE American Public Health Association records its appreciation of the participation in its deliberations during this Annual Meeting week of Dr. Irvin Abell, President of the American Medical Association. It records with pleasure its agreement with the approval in principle, at a recent special session of the House of Delegates of the American Medical Association, of the content of the national health program presented by the Interdepartmental Committee to the National Health Conference. The Association pledges its continued coöperation and support to the American Medical Association in the translation of this policy into action.

EFFECTIVE CONTROL OF DRUGS

WHEREAS, it appears that the health and welfare of the American public are being jeopardized in a large way by an enormous volume of drug preparations advertised and sold through consumer channels for self-medication; and,

WHEREAS, the federal government through the passage of the Wheeler-Lea Amendment and the Copeland Act at the last session of the National Congress, is now equipped to deal adequately from a federal standpoint with abuses involving harmful and dangerous drugs as well as false and misleading advertising of every description in regard to food, drugs and cosmetic preparations offered for sale in interstate traffic, be it, therefore,

RESOLVED that the American Public Health Association, through its constituent member-

ship and allied health organizations exert every possible effort to coöperate with the federal government in the realization of these most laudable objectives; and to this end, be it further

RESOLVED that the American Public Health Association recommend to those state health departments having jurisdiction over food and drug control, that steps be taken as expeditiously as possible to revise the existing state laws, if necessary, so as to harmonize with the federal regulations in order that complete coördination and mutual coöperation may be effected, and all unnecessary duplication be eliminated.

BASIC REQUIREMENTS FOR MEDICAL PRACTICE AND THE USE OF ANIMALS IN SCIENTIFIC RESEARCH

WHEREAS, despite the fact that one of the proudest chapters in the history of American Medicine is the improvement in training and professional qualifications of American physicians, there is still occasional evidence of lack of understanding by some groups of the general public of these accomplishments. From time to time in the various states and sections of this country there appear legislative proposals inimical to the continued progress of scientific medicine and public health. Many of these proposals if passed would seriously injure the health of the public and prove serious obstacles to biological research and curative and preventive medicine.

RESOLVED that the American Public Health Association hereby records its firm conviction that those who would practise the healing arts and sciences must be thoroughly trained in the basic sciences such as anatomy, chemistry, physics, physiology, bacteriology, and the like, as well as in the clinical subjects such as medicine, preventive medicine, surgery, pediatrics, obstetrics, and the like, and that such training requires a minimum of high school graduation, two years of academic college study, four years in a recognized Class A medical school, and one year of internship in an approved hospital or laboratory.

That minimum standards of training now upheld by Class A medical schools in the United States are reasonable and proper, and that none should administer to the sick in the capacity of physician without having met these requirements or their full equivalent and without being licensed to practise medicine by a state medical examining board.

BE IT FURTHER RESOLVED that the American Public Health Association considers laboratory work with animals essential to re-

search into the still unknown areas in biology, medicine, preventive medicine, surgery, therapeutics, and public health. That even as we are dependent for our food supply on the lower animals, so likewise are we dependent upon the so-called laboratory animals for sera, vaccines, and other medicines which result in enormous savings of both human and animal life;

That restriction of the supply of such animals to any responsible institution or organization engaged in medical training, scientific research or manufacture of therapeutic agents would be a serious menace to the public health.

NEW AFFILIATED SOCIETIES

AT the Annual Meeting of the A.P.H.A. in Kansas City, three state public health associations were approved as Affiliated Societies of the American Public Health Association, making a total of nineteen. Names of these new societies and their officers are:

Arizona Public Health Association
President—George F. Manning, M.D., Flagstaff
President-Elect—W. W. Peter, M.D., Window Rock
First Vice-President—Noel McKeehan, Phoenix
Second Vice-President—Beth Woolfolk, Phoenix
Secretary-Treasurer—Marion E. Stroud, Phoenix

Colorado Public Health Association
President—A. L. Beaghtler, M.D., Denver
Vice-President—Roy L. Cleere, M.D., Denver
Treasurer—Omer Gillett, M.D., Colorado Springs
Acting Secretary—Marie P. Fackt, M.D., Denver

Utah Public Health Association
President—L. L. Daines, M.D., Salt Lake City
President-Elect—S. G. Paul, M.D., Salt Lake City
Treasurer—D. C. Houston, Salt Lake City
Secretary—S. E. Gilchrist, Salt Lake City

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Leonides A. Almazan, M.D., Pasco Reforma 10, Mexico City, Mexico, Chief, Public Health Dept. of Mexico
 Henry H. Asher, M.D., Ozark, Mo., District State Health Officer
 Huston J. Banton, M.D., M.P.H., Fort Riley, Kans., Director of Laboratory and Assistant Inspector
 J. Nelson Barger, M.D., Albany, Mo., County Health Officer
 Edgar A. Belden, M.D., 811 Virginia Ave., Columbia, Mo., District State Health Officer
 Arnold S. Benson, M.D., 30 Island Ave., Aurora, Ill., Health Commissioner
 Claude M. Eberhart, M.D., 1009 Broadway, Highland, Ill., District Health Supt., State Dept. of Public Health
 Charles F. Engelking, M.D., C.P.H., 76 S. Thornton Ave., Dalton, Ga., Whitfield County Commissioner of Health
 Floyd B. Gillespie, M.D., Fairbanks, Alaska, Deputy Commissioner of Health
 Phares Y. Greene, M.D., Graham, N. C., Alamance County Health Officer
 Beatrice T. Hagen, M.D., Court House, Zanesville, O., Muskingum County Health Commissioner
 Fred P. Helm, M.D., State Board of Health, Topeka, Kans., Secretary and Executive Officer
 Forrest A. Kelley, M.D., 103½ E. 9th, Winfield, Kans., Cowley County Health Officer
 Ralph R. Kelley, M.D., Savannah, Mo., County and State Deputy Health Officer
 Lawrence J. Linck, 414 S. Boulevard, Evanston, Ill., Director, Chicago Syphilis Control Project and Special Consultant, Division of Venereal Diseases, U. S. Public Health Service
 Hugh B. Martin, Municipal Bldg., Englewood, N. J., Health Officer
 Grady F. Mathews, M.D., Tahlequah, Okla., District State Health Officer.
 Herbert L. Newcombe, M.D., M.P.H., South Central District Health Unit, Twin Falls, Idaho, Assistant Director
 L. A. Proctor, M.D., 112½ S. 18th, Parsons, Kans., Health Officer
 Albert J. Randall, M.D., 723-56 St., Kenosha, Wis., Director of Public Health

Howard G. Romig, M.D., Anchorage, Alaska,
Assistant Health Commissioner

Dr. Severi Savonen, Yrjonkatu, Helsinki, Finland, Secretary, Finnish National Anti-Tuberculosis Assn.

Richard Sears, M.D., White Cloud, Mich.,
Director, District Health Unit 5

Joseph W. Spearing, M.D., P. O. Box 403,
Cimarron, Kans., County Health Officer

George C. Stucky, M.D., Eaton County Health
Dept., Charlotte, Mich., Director

J. V. Van Cleve, M.D., 906 Brown Bldg.,
Wichita, Kans., Director of Syphilis Clinic,
Sedgwick County Clinic and Hospital

Theodore L. Waddle, M.D., Dexter, Mo., Dis-
trict State Health Officer

Roy A. Walton, M.D., D.P.H., 41 Ave. and
Fraser St., Vancouver, B. C., Canada, Direc-
tor, Metropolitan Health Unit 4

Anderson F. Whitsitt, M.D., C.P.H., Chester-
town, Md., Deputy State Health Officer and
Kent County Health Officer

Laboratory Section

Flora H. Acton, 1305 W. 16 St., Topeka,
Kans., Bacteriologist, State Public Health
Laboratory

L. H. Allwardt, D.Sc., 121 W. Main St.,
Chillicothe, O., Bacteriologist, Dept. of
Health

Jean Christopher, Public Health Laboratory,
Topeka, Kans., Bacteriologist

R. J. Gibbons, M.D., Laboratory of Hygiene,
John & Sussex Sts., Ottawa, Ont., Canada,
Senior Bacteriologist

Alfred G. Karlson, D.V.M., 914 W. Center,
Rochester, Minn., Fellow, Mayo Founda-
tion for Medical Education and Research

Frederick C. Mortensen, Ph.D., Station Hos-
pital, Fort Leavenworth, Kans., Captain,
Sanitary Corps, U. S. Army

Murrell O. Robinson, V.M.D., Box 263,
Auburn, Ala., Professor of Bacteriology,
Alabama Polytechnic Institute

Robert M. Shaw, M.D., D.P.H., Provincial
Laboratory, Univ. of Alberta, Edmonton,
Alta., Canada, Professor of Bacteriology and
Hygiene

Henry C. Sweany, M.D., 5601 N. Pulaski Rd.,
Chicago, Ill., Medical Director, Research
and Laboratories, Chicago Municipal Tubercu-
losis Sanitarium

Harriette D. Vera, Ph.D., Dept. of Physiology,
Goucher College, Baltimore, Md., Instruc-
tor in Bacteriology

Vital Statistics Section

Wayne F. Caskey, Ph.D., 2312 S. Nash St.,
Arlington, Va., Head. Admr. Studies Unit,
Bureau of Old-Age Insurance, Social Se-
curity Board

Frances Idol, 1100 W. Main St., Jefferson
City, Mo., Assistant State Registrar

Francis E. Kester, State Board of Health,
Madison, Wis., Acting Director of Vital
Statistics

Margaret D. Lang, State Dept. of Health,
Bismarck, N. D., Director, Division of
Vital Statistics

Gordon N. Perry, Bureau of Economics and
Statistics, Parliament Bldgs., Victoria, B. C.,
Canada, Director

Public Health Engineering Section

Buford D. Baker, 2619 Indiana, Topeka,
Kans., County Sanitarian

Lewis Dodson, 2410 Seton, Austin, Tex.,
Itinarat Instructor of Sewage and Sanita-
tion, State Dept. of Education

Glen A. Harwell, Osceola, Mo., Public Health
Engineer, State Board of Health

John A. Logan, 1613 E. Broadway, Columbia,
Mo., Instructor in Sanitary Engineering,
University of Missouri

Richard M. McLaughlin, 17 Merritt Ave.,
White Plains, N. Y., Acting Director,
Division of Sanitation, Westchester County
Dept. of Health

George D. Newton, Fulton County Health
Dept., Atlanta, Ga., Sanitary Engineer

M. W. Pirkle, City Hall, Marietta, Ga., Act-
ing Division Engineer, State Dept. of Public
Health

M. Dwight Sanders, Swift & Co., Union
Stock Yards, Chicago, Ill., Research and
Development in Industrial Waste Treatment

Ivan F. Shull, 300 S. Broadway, Wichita,
Kans., County Sanitarian

James H. Stephens, State Board of Health,
Columbia, S. C., Sanitary Engineer, Field
Training Unit

J. Harold Tillman, 2730 Wheeling St., El Paso,
Tex., Sanitarian, City-County Health Dept.

Ben L. Williamson, Rm. 15, Marvin Hall,
Univ. of Kansas, Lawrence, Kans., Asst.
Engineer, Division of Sanitation, State
Board of Health

Industrial Hygiene Section

Frederick H. Goldman, Ph.D., National Insti-
tute of Health, Washington, D. C., Chemist,
Division of Industrial Hygiene, U. S. Pub-
lic Health Service

Richard D. Mudd, M.D., Ph.D., Chevrolet-
Grey Iron Foundry, Saginaw, Mich., Med-
ical Director

Food and Nutrition Section

Raoul F. Cowley, Ave. de Belgica 7, Alturas
de Almendares, Marianao, Cuba, Technical
Adviser, National Technical Milk Com-
mission of Cuba

Graphs: How To Make and Use Them—By *Herbert Arkin and Raymond R. Colton*. New York: Harper, 1936. 224 pp. Price, \$3.00.

This book should be on bookshelves next to "Statistical Methods" by the same authors. It is the first book on graphs in which we have seen all of the "tricks of the trade" listed.

The first three chapters are devoted to principles, construction, and equipment, in which are set forth the various kinds of paper, pens, inks, and lettering guides. Separate chapters are devoted to the different types of charts where in each case may be found a list of common errors to avoid. The authors cite rules for titles and footnotes which if followed would take the curse off many charts. They also stress the point that charts should be simple and should tell one story, not many. Chapters are also given to reproduction of graphs and the preparation of statistical tables and reports. There is also a complete index.

The entire book is written in the simple straightforward style that made *Statistical Methods* so valuable.

While it does not confine itself to the presentation of public health statistics all of the material is applicable to this field and it will be of great assistance to anyone interested in or concerned with modern graphic presentation of public health statistics for both the lay public and the professional groups.

E. J. CROSS

How To Live—By *Irving Fisher, LL.D., and Haven Emerson, M.D.* (20th ed.) New York and London: Funk and Wagnalls, 1938. 422 pp. Price, \$2.50.

A book which has reached its 20th edition and the worth of which has been recognized in every part of the United States, does not call for a review—only an announcement of a new edition. However, this last volume

sees Dr. Haven Emerson as co-author with Professor Irving Fisher in place of the late Dr. Eugene Lyman Fisk, who was associated with Professor Fisher in getting out the earlier editions, and to whose memory the book is now dedicated.

This edition has followed the earlier ones in bringing the subject matter up to date and in presenting the most recent authoritative conclusions on each subject discussed. The authors regard the book as unique and even radical in its recommendations, but properly hold that it is based on the work of conservative advisers and hope that they are just a little ahead of the world, which will eventually catch up with them.

A striking feature is the 32 appendices, each by a specialist in his field. These appendices constitute approximately two-thirds of the volume. A good index adds to the value. It should be noted that the royalties from the sale of this book will be donated to meet the expense of the Vitality Records Office through which valuable information is being collected as to the influence of habits on health.

It can be recommended without reserve. It will unquestionably maintain the high place in the regard of the public earned in the past.

MAZÛCK P. RAVENEL

The Radiology of Pulmonary Tuberculosis—By *J. E. Bannen, M.B., Ch.B., D.M.R.E.* Baltimore, Md.: Wood, 1937. 156 pp. Price, \$4.50.

This is an excellent synopsis of the subject. To those in public health work who desire to refresh themselves concerning the pathology of the lungs as revealed by X-ray, it should be of inestimable help.

There is a good chapter on the physical examination of the chest and the clinical aspects of pulmonary tuberculosis. The illustrations are adequate

- Nelle R. Morris, 3027 Summit St., Sioux City, Ia., Director, Public Health Nursing
- Pearl Nelson, Cameron, Mo., District Health Nurse

- Clara Mears, R.N., 805 Ohio St., Lawrence, Kans., County Public Health Nurse
- Clifford R. Taylor, D.D.S., 1132 White, Ann Arbor, Mich., Trainee (Director of Dental Health Appointee for South Dakota)

STANDARD METHODS FOR THE EXAMINATION OF DAIRY PRODUCTS

CHANGES IN NEW EDITION

THE following are the most important changes in *Standard Methods of Milk Analysis* (new title *Standard Methods for the Examination of Dairy Products*) as approved by the Laboratory and Food and Nutrition Sections of the American Public Health Association at the Annual Meeting in Kansas City, Mo., October 25-28, 1938.

1. The Seventh Edition of this report is to include Bacteriological Methods prepared by a Committee from the Laboratory Section, Bioassay Methods for Vitamin D Milk prepared by a Committee from the Food and Nutrition Section, and Chemical Methods prepared by the Association of Official Agricultural Chemists.

2. The scope of the report has been broadened to cover Dairy Products, in general. The Ice Cream Section, which now includes methods for making bacterial counts for Plain Ice Cream only, is to be still further developed during the coming year in coöperation with the Joint Committee on Standard Methods for the Examination of Frozen Desserts maintained by the Laboratory, and the Food and Nutrition Sections to cover the broader field of Frozen Desserts. Methods for making Yeast and Mold Counts from butter are also included. A Referee on Sediment Tests for all dairy products is to be appointed.

3. Part I Bacteriological Methods is divided into eleven sections. The first five sections cover sampling, methods of making agar plate counts, direct microscopic counts, the methylene blue reduction technic and sediment tests. The four following sections describe methods for the isolation and identification of coliform bacteria, hemolytic streptococci, tubercle bacilli, and the organisms that cause undulant fevers, respectively. Section 10 includes the ice cream methods, and Section 11 the butter methods.

4. The text of the bacteriological portion of the report has been entirely rewritten and arranged in a more logical sequence. A de-

tailed subject Index is to be prepared, in addition to the Table of Contents.

5. The following are the most important changes approved in the Standard Agar Plate Count technic:

(a) Beginning July 1, 1939, standard agar is to have the following composition and reaction:

Bacto-Tryptone .	5 gr.	
Bacto-meat extr.	3 gr.	
Glucose	1 gr.	
Skim milk	10 c.c.	(Where dilutions are
Agar	15 gr.	greater than 1:10)
Reaction	pH 6.6 to 7.0	
Preferred reaction	7.0	

(b) While incubation at 37° C. (not 37.5° C.) is to be continued until laboratories doing milk work are more generally equipped with approved incubators, the variation in temperature permitted was placed at 35 to 37° C., rather than 35.5 to 37.5° C., as at present.

(c) As a result of the findings of various research workers, it is required that agar plates be counted under constant illumination and the use of the Quebec Colony Counter is strongly recommended.

(d) The recommendations regarding types of laboratory incubators and incubator rooms as given in the present (Sixth) edition are made mandatory so that the only incubators approved are the water jacketed and anhydric laboratory type incubators with low temperature heating units operating at temperatures only slightly in excess of 37° C.; and incubator rooms of proper construction.

(e) Specifications for pipettes, dilution bottles, non-absorbent closures, etc., have been drawn up in greater detail than previously.

(f) Methods have been developed for making more accurate rinse counts from glass and paper milk bottles that are nearly sterile.

6. The uses of the direct microscopic method and particularly its usefulness for the examination of pasteurized milk have been described in greater detail than previously. It is required that all agar plate counts be checked microscopically frequently enough to detect the presence of excessive numbers of

bacteria present in the milk and cream where they do not grow on standard agar plates incubated at 37° C. It is only by checking in this way that all samples containing excessive numbers of bacteria can be detected. A high class milk supply does not contain an excessive number of bacteria, either living or dead.

7. (a) The methylene blue thiocyanate tablets approved at the New Orleans meeting (1936), having been standardized and found satisfactory in actual use, are accepted as standard.

(b) Reference is made to the modified form of the methylene blue reduction technic now officially approved in England.

(c) No reference is made to the resazurin test as it is felt that further study must be made before the significance of the results secured by this technic will be evident.

8. Improvements have been made in the text covering the sediment technic. The suggested 1937 Connecticut State Standards are included.

9. Brilliant green lactose bile broth, sodium formate ricinoleate broth, violet red bile agar, and sodium desoxycholate agar are approved for use in detecting coliform bacteria in dairy products.

10. Methods for plating on blood agar and the use of Burri agar slants are given in the section on methods of detecting pathogenic, usually hemolytic streptococci. Cross reference is made to the report prepared by the Committee on Diagnostic Procedures and Reagents of the Laboratory Section which gives methods of identifying species of streptococci by cultural and serological procedures. These are to be used where exact identification of species is desired.

11. The tentative methods for the identification of tubercle bacilli in milk and cream as

given in the *Year Book* for 1934-1935 are now included as standard methods.

12. The tentative methods for the identification of bacteria belonging to the genus *Brucella* as given in the *Year Books* for 1934-1935 and 1935-1936 are now included as standard methods.

13. Little change has been made in the section describing methods for making bacterial counts from plain ice cream. It is expected that this section will be rewritten in the near future in coöperation with the Committee on Standard Methods for the Examination of Frozen Desserts.

14. Directions for carrying out yeast and mold counts on butter are given for the first time. No directions for making sediment tests from butter are given as yet. These methods are under study in coöperation with referees working with similar methods for other dairy products.

15. The directions given in Part II for the Bioassay of Vitamin D milk are based on the directions for this method as given in the *U.S. Pharmacopoeia*, Supplement, p. 91, and are in harmony with the directions adopted by the Association of Official Agricultural Chemists.

It is expected that the new (Seventh) edition of the report will be in print during the early part of 1939.

COMMITTEES ON STANDARD METHODS FOR THE EXAMINATION OF DAIRY PRODUCTS

ROBERT S. BREED, *Chairman*
FRIEND LEE MICKLE, *Chairman*
Frozen Desserts
HENRY T. SCOTT, *Chairman*
Vitamin D Bio-assay of Milk

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge. Public health nurses are registered with the Nurse Placement Service, 8 South Michigan Avenue, Chicago, Ill., with which the Association coöperates.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS AVAILABLE

WANTED—(a) County health commissioner; public health training and experience required; southeast. (b) Young physician, under 35, for position with state department of health; must be willing to take course of training before being assigned to duty. (c) Young public health man for interesting position in southwest; special training in either obstetrics or pediatrics desirable; woman eligible. (d) School nurse; college graduate, 30-40, with public health certificate; full charge in small town school system with total enrollment of 900; ability to launch sex education program for students and mothers important; minimum \$1,700, increasing annually; immediately available, Chicago area. (e) Instructor in bacteriology and public health; degree in bacteriology from medical school required; state university school; considerable research. (f) City health commissioner; physician with minimum 5 years' experience required; one 40-45 with C.P.H. or M.P.H. preferred; \$5,000; South. Write: 120, Medical Bureau, Pittsfield Building, Chicago, Ill.

POSITIONS WANTED

Physician, M.D., University of Virginia; excellent background, seeks position as health officer in well organized health department. A388

Physician, M.D., Class A medical school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer, seeks full-time administrative position in city or county. A367

Physician, experienced in health administration of cities and states, will consider attractive opening in maternal and child health or health education. A343

Well qualified physician, with C.P.H. from Johns Hopkins; experienced as school physician and in college teaching, will consider city or county administrative position or teaching and student health service. A383

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; now employed, is available as venereal disease control officer. A363

Physician, M.D., C.P.H., 2 years' experience as district health officer; anxious to do venereal disease control work or epidemiology. A345

Physician, M.D., A.B., 30 years city health department. Administrative, educational and research experience; also familiar with venereal disease work. A295

Physician, age 34; M.D., University of Wisconsin; M.P.H., Harvard; specializing in industrial hygiene, will consider general administration. A342

HEALTH EDUCATION

Well qualified woman in health education wishes position as health coördinator or health counselor. Has wide experience, and Ph.D. from New York University. H236

Young woman, M.A., Health Education, Teachers College, Columbia University; with splendid international experience, seeks position as director of health education with preference for New York City. H369

Young woman, M.S.P.H., University of Michigan, experienced in laboratory research and health education, is available for research or investigative work. H303

Woman, M.D., Boston University; special work Columbia and Massachusetts Institute of Technology; one year's experience in state hospital; interested in psychiatry, desires position in the east in hospital for mental diseases or industrial school. H247

MATERNAL AND CHILD HEALTH

Woman physician, graduate of University of Iowa, who has directed state bureau of maternal and child health, now employed, will consider another position. C318

Woman physician, with excellent medical training and background of public health nursing experience, seeks position in maternity and infancy work. C376

LABORATORY

Bacteriologist and pathologist with wide administrative experience; Ph.D., Brown University; will consider leading position in this field. L371

(Continued on p. 1450)

Experienced laboratory director with background of dairy products manufacture and research in control methods; University of Wisconsin, M.S. and Ph.D.; desires administrative position with food manufacturing or processing industry, or association with health department doing routine and research work in food control. L381

Capable research worker; Ph.D., trained at University of Southern California and Pasteur Institute, seeks position directing laboratory, in research work or field investigation. Has taught bacteriology, directed state hygiene laboratory and hospital laboratories. L315

Young woman, A.B., Bates College; several years' experience in various state laboratories, desires position as bacteriologist. L253

Bacteriologist with training at C.C.N.Y., N.Y.U. and Cornell Medical College, wishes laboratory position in bacteriology; east or southwest. M351

Young woman, A.B., major in bacteriology; 9 years' experience; now employed in a clinical laboratory; desires position in bacteriology or serology in a health department laboratory or in research. L382

Laboratory technician, B.Sc. degree; with experience in Army, state public health laboratory, and U. S. Public Health Service field laboratory, seeks position in medical school or university. L379

Bacteriologist and serologist, A.B., University of Kansas; at present bacteriologist in charge, public health laboratory; will consider another position. L390

SANITARY ENGINEERS

Sanitary engineer; courses at Rutgers University; with 17 years' experience in design, research and construction of water and sewage plants, as well as aerial pollution surveys; desires position, preferably research. E321

Graduate sanitary engineer with service under U.S.P.H.S. and state departments of health, especially interested in filtration plant design and operation and shellfish sanitation, seeks employment. E356

Public Health engineer, B.S. in Sanitary Engineering from Massachusetts Institute of Technology, experienced in Massachusetts, Connecticut and Kentucky, seeks position as sanitary or public health engineer with health department. E380

Experienced sanitary engineer, graduate of Massachusetts Institute of Technology, seeks responsible position. E372

MISCELLANEOUS

Young man, age 27, S.B., Massachusetts Institute of Technology; A.M., Boston Uni-

versity; M.S. in Biochemistry, University of Michigan; 2 years' graduate work in public health; experienced in chemical, bacteriological and biochemical research; teaching experience in college hygiene, desires a position in a food industry involving research or control. M374

Experienced teacher in bacteriology and public health; Ph.D., Cornell; now professor in Grade A medical school, will consider teaching, executive or administrative position. M327

Experienced public health nurse executive, Fellow A.P.H.A., is available for responsible position. N384

Industrial hygiene engineer, B.S. in Chemical Engineering, S.M. in Sanitary Engineering (Industrial Hygiene) from Harvard Graduate School of Engineering; field experience; desires position with public health department or private health agency. M391

SITUATIONS WANTED: (a) *Young physician*: B.S., M.D. degrees, leading schools; graduate courses in physiologic hygiene, community health problems and epidemiology, hygiene and public health; age 31; will go anywhere. (b) *Young woman physician*: extensive graduate training in pediatrics; 4 years, child hygiene division, state health department; several years, private practice pediatrics; wishes to return to full-time public health work. (c) *Public health nurse*, B.A. degree; graduate of one of country's leading training schools; postgraduate training public health and hygiene, state university. (d) *Health educator*; graduate nurse, with B.S. degree; social service certificate; 3 years' experience social service; 4 years, industrial nursing; 10 years, director of health council. (e) *Bacteriologist*, A.B., M.S. degrees, state university; ten years, city bacteriologist and chemist, city health department. WRITE: 121, Medical Bureau, Pittsfield Bldg., Chicago, Ill.

POSITIONS AVAILABLE

District Health Officer; 3 Vacancies; Salary \$4,750. Applicants must have been residents of the City of New York for 3 years at the time of appointment. Duties: Administrative charge of the activities of Health Department in a district of about 250,000 population. Requirements: M.D. degree, 1 or more years of graduate training in public health, and 2 years' experience as a health officer or 3 years' experience in a responsible administrative position of the type which will fit one to be a health officer. Applications: Open December 7 to 28, 1938. For further details apply to Municipal Civil Service Commission, Municipal Bldg., New York City.

NEWS FROM THE FIELD

DELTA OMEGA OFFICERS

IN connection with the American Public Health Association meeting at Kansas City, Delta Omega, the honorary society in Public Health, held its annual meeting on October 25. Of the 749 living members, 90 were present. The society has six chapters in institutions offering courses which lead to degrees in public health.

The officers for the ensuing year are: Dr. John Sundwall, of Ann Arbor, Mich., President; Dr. M. E. Barnes, of Iowa City, Ia., Vice-President; and Dr. Clarence L. Scamman, 41 E. 57th St., New York City, Secretary-Treasurer.

A NEW FORM OF BIOLOGICAL ABSTRACTS FOR 1939

A NEW plan for the publication of *Biological Abstracts* beginning with 1939 has been adopted by the Board of Trustees. It provides for the usual monthly issue of abstracts covering promptly a definite list of journals in all fields of biology. To meet the demands of biologists who wish to subscribe for a special group of subjects, the whole issue will be broken up into five parts:

I. *General Biology*, to include General Biology, Biography-History, Bibliography, Evolution, Cytology, Genetics, Biometry and Ecology.

II. *Experimental Animal Biology*, to include Animal Physiology, Nutrition, Pharmacology, Pathology, Anatomy, Embryology, and Animal Production.

III. *Microbiology and Parasitology*, to include Immunology, Bacteriology, Viruses, Parasitology, Protozoölogy, and Helminthology.

IV. *Plant Sciences*, to include Phytopathology, Plant Physiology, Plant Anatomy, Palaeobotany, Systematic Botany, Agronomy, Horticulture, Forestry, Pharmacognosy, and *Palaeobotanical Botany*.

V. *Palaeozoölogy*, to include Palaeozoölogy, Protozoölogy, Helminthology,

Systematic Zoölogy, and Economic Entomology.

Subscribers to any of these parts will receive the indexes to the whole of *Biological Abstracts*.

To insure close contact on the part of biologists in every field with this service being conducted for them, the National Societies concerned are being invited to set up committees to help develop standards and editorial policies in their respective fields.

Biological Abstracts exists on a self-supporting basis, operates without profit, and sells its service at cost. For further information apply to the Business Manager, *Biological Abstracts*, University of Pennsylvania, Philadelphia, Pa.

"TYPHOID MARY" DIES OF STROKE AT 68

THE first carrier of typhoid bacilli identified in America and consequently known as Typhoid Mary, Mary Mallon, died November 11 in Riverside Hospital on North Brother Island, New York.

With the exception of a 5 year period from 1910 to 1915, this isolated spot in the East River had been her home since 1907, when she was discovered by George A. Soper, engineer and sanitary expert, and found to be a veritable peripatetic breeding ground for the bacilli. Fifty-seven original cases and 3 deaths had been attributed to her.

PSITTACOSIS ORDINANCES IN BALTIMORE

A CITY ordinance has been enacted in the City of Baltimore in order to prevent the reappearance of psittacosis or parrot fever.

This ordinance prohibits the importation, breeding, sale or distribution of birds of the psittacine family.

VIRGINIA ANNOUNCES FREE ANTI-SYPHILIS DRUGS

THE Virginia State Health Department has announced that free anti-syphilitic drugs are available to the medical profession for the treatment of all cases of syphilis, regardless of the patient's economic status. *The Virginia Medical Monthly* reports that health officers in cities and counties served by a full-time health department have been furnished a supply of drugs for distribution to hospitals, clinics and private physicians in their respective territories.

Physicians practising in territories not served by a full-time health department are to forward their requisitions to the State Health Department.

CHRISTMAS MEETING OF CANADIAN PUBLIC HEALTH ASSOCIATION

THE Laboratory Section of the Canadian Public Health Association will hold its Seventh Annual Christmas meeting in Toronto, December 19 to 21.

John Gordon, M.D., Ph.D., Professor of Hygiene and Preventive Medicine of Harvard University, will be the guest speaker.

HOSPITAL FOR DRUG ADDICTS

THE U. S. Public Health Service Hospital for drug addicts at Fort Worth, Texas, was dedicated recently.

This is the second such institution in the country, and was built at a cost of approximately \$4,000,000.

NEW TYPHUS ANIMALS

SIX new species of animals native to America have been added to the list of those susceptible to endemic typhus fever, and therefore possible intermediate reservoirs of infection which may be tapped by insects and thus transferred to man, the U. S. Public Health Service reported.

The gray and fox squirrel, the cottontail and swamp rabbit, the chipmunk and the skunk have been found to match the typhus classification of the woodchuck, flying squirrel, opossum, and the meadow, whitefooted, oldfield, cotton and golden mouse and the wood, cotton and rice rat.

MICHIGAN PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

NEW officers for the forthcoming year were elected as follows by the Michigan Public Health Association at its recent annual meeting:

President—John Lavan, M.D., Grand Rapids

Vice-President—M. R. Kinde, M.D., Battle Creek

Secretary-Treasurer—Marjorie Delavan, Lansing

Representative on A.P.H.A. Governing Council—Don W. Gudakunst, M.D., Lansing

TEXAS PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

AT its recent Annual Meeting the Texas Public Health Association elected the following officers to serve for the next year:

President—Walter Kleberg, M.D., Galveston

1st Vice-President—Graham Hatch, Dallas

2nd Vice-President—Mildred Garrett, R.N., Austin

3rd Vice-President—C. B. Young, M.D., Tyler

Secretary-Treasurer—P. A. Kerby, Austin

WEST VIRGINIA PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

AT its recent Annual Meeting, the West Virginia Public Health Association elected the following officers to serve during the coming year:

President—Edwin Cameron, M.D., Morgantown

Vice-President—Bruce H. Pollock, M.D., Point Pleasant

Second Vice-President—Claude A. Thomas, M.D., Martinsburg

Secretary—Harry K. Gidley, Charleston

MISSISSIPPI VALLEY MEDICAL SOCIETY
1939 ESSAY AWARD

THE Mississippi Valley Medical Society offers \$100, a gold medal, and a certificate of award for the best unpublished essay on a subject of interest and practical value to the general practitioner of medicine. Entrants must be members of the American Medical Association. The winner will be invited to present his contribution before the next annual meeting of the Mississippi Valley Medical Society at Burlington, Iowa, September 27, 28, 29, 1939, the Society reserving the exclusive right to first publish the essay in its official publication — the *Mississippi Valley Medical Journal (Incorporating the Radiologic Review)*.

Contributions must not exceed 5,000 words, be typewritten in English in manuscript form, submitted in 5 copies, and must be received not later than May 1, 1939. Further details may be secured from Harold Swanberg, M.D., Secretary, Mississippi Valley Medical Society, 209-224 W. C. U. Building, Quincy, Ill.

MICHIGAN BUREAU OF PUBLIC HEALTH
NURSING

A BUREAU of Public Health Nursing has been established as one of the administrative divisions of the Michigan Department of Health.

Miss Helen Bean, Public Health Nursing Consultant with the Division of Domestic Quarantine of the U. S. Public Health Service, has been appointed Director of this new bureau.

SYLVATIC PLAGUE LABORATORY

THE University of California is to be equipped with a laboratory for the study and control of sylvatic plague.

This work will be under the leadership of Dr. Karl F. Meyer, Director of the George Williams Hooper Foundation of the University, and Chairman of

the Committee on Sylvatic Plague of the Western Branch A.P.H.A.

ARKANSAS EMPLOYS DENTISTS

FIFTEEN part-time dentists have been employed by the Arkansas State Board of Health to conduct dental health programs in full-time county units.

MORE PUBLIC HEALTH NURSING IN 1937

SEVEN and one-half per cent more public health nurses were employed in 1938 than in 1937, according to a report released by the U. S. Public Health Service and the U. S. Children's Bureau.

These statistics, collected through the state health departments, show that 23,271 public health nurses were employed in 1938 as compared with 21,656 in 1937.

NATIONAL RESOURCES COMMITTEE
REPORTS

THE National Resources Committee has reported on drainage base problems and programs and has listed recommendations for construction of pollution abatement facilities in various parts of the United States.

The number of these projects totals 3,484 and the estimated cost is \$667,-000,000. A tabulation of the projects by area with their estimated cost is available through the office of the American Public Health Association, 50 West 50th Street, New York, N. Y.

JANUARY 1938 JOURNAL NEEDED

ASSOCIATION stock of the January, 1938, issue of the *American Journal of Public Health* is exhausted. The office will pay postage on any copies from members or subscribers. Address: American Public Health Association, 50 West 50th Street, New York, N. Y.

PUBLIC HEALTH COURSE FOR DENTISTS
COLUMBIA University School of Dentistry and Oral Surgery, during the current school year, is offering a course in public health for dentists.

This course, planned to provide dentists with essential training in public health, leads to a master of science degree.

PNEUMONIA SERUM FOR BALTIMORE INDIGENTS

INDIGENT hospital patients in the City of Baltimore have been supplied pneumonia serum, made possible by an appropriation to the Health Department.

Up to October 1, the Bureau of Laboratories of the Baltimore City Health Department distributed 5 million units of this serum at a cost of approximately \$2,000 among 11 hospitals for the treatment of 37 pneumonia patients. Among the 37 persons receiving the serum, there were 10 deaths and 27 recoveries.

SOUTHERN MEDICAL ASSOCIATION

AT the Southern Medical Association meeting, held in Oklahoma City recently, Arthur T. McCormack, M.D., of Louisville, Ky., immediate Past-President of the American Public Health Association, was elected President-elect of the Southern Medical Association; and Philip E. Blackerby, M.D., of Louisville, Ky., was elected Secretary-Treasurer.

STATE CONFERENCE ON PUBLIC HEALTH

AMONG the speakers scheduled to speak at the State Conference on Public Health, for Springfield, Ill., November 30 and December 1, were: Wilson G. Smillie, M.D., of New York, Harry S. Mustard, M.D., of New York, Adolph S. Rumreich, M.D., of Washington, Nels Nelson, M.D., of Massachusetts, Gaylord Anderson, M.D., of Minnesota, Arthur T. McCormack,

M.D., of Kentucky, Sophie Nelson of Boston, and C. C. Applewhite, M.D., of the U. S. Public Health Service, Chicago.

CHANGES IN NEW YORK STATE

DEPARTMENT OF HEALTH

The following is a list of promotions and new assignments to the staff of the New York State Department of Health, which have been effected during October:

Ernest L. Stebbins, M.D.* Assistant Commissioner in Charge of Preventable Diseases.
 James E. Perkins, M.D., Dr.P.H.*—Director of Communicable Diseases.

Paul A. Lembcke, M.D.†—Epidemiologist in the Division of Communicable Diseases.

The following district officers have been appointed and their assignments are indicated:

Samuel Hyman, M.D.,† Utica
 Franklyn B. Amos, M.D.,† Amsterdam
 Harry L. Chant, M.D.,† Middletown
 Hollis S. Ingraham, M.D.,† Kingston
 Frank E. Coughlin, M.D.,* Albany, has become District State Health Director, with supervision over the Eastern New York State districts.

Robert L. Vought, M.D., Jamestown. Assistant District State Health Officer, has been placed in charge of the Jamestown sub-district office.

Gordon R. Gray, M.D., Batavia, Assistant District State Health Officer, has been placed in charge of the Batavia subdistrict office.

The following physicians have been appointed as Assistant District State Health Officers:

Wendell R. Ames, M.D.,† Lester Levingson, M.D.,† Bernard M. Blum, M.D.,† Walter C. Levy, M.D.,† John J. Bourke, M.D.,† Wilfred L. J. McDonald, M.D.,† James C. Boland, M.D.,† James J. Quinlivan, M.D.,† Simon J. Gormley, M.D., William M. Smith, M.D.,† Harvey S. Kinne, M.D.,† Ralph P. Vincent, M.D.

The following physicians have been appointed as Epidemiologist-in-training:

Robert Y. Gromet, M.D., Thistle McKee, M.D.

* Fellow A.P.H.A.

† Member A.P.H.A.

PERSONALS

Central States

CARL A. WILZBACH, M.D.,* has been appointed Health Commissioner of the City of Cincinnati, Ohio. Dr. Wilzbach has been the Director of Public Health Education of the Cincinnati Public Health Federation.

DR. JOHN ESSER, of Perham, Minn., has been appointed a member of the Minnesota State Board of Health, to succeed DR. SAMUEL Z. KERLAN, of Aitkin.

DR. ALBERT G. SCHULZE, of St. Paul, Minn., has been appointed a member of the Minnesota State Board of Health.

ANTONY TRIOLO, M.D.,† formerly of Philip, S. D., has been appointed Health Officer of Pennington County, succeeding DR. HORACE D. LIEN, of Rapid City, who has resigned to join the staff of the Fort Bidwell Hospital, Fort Bidwell, Calif.

Eastern States

FRANKLYN B. AMOS, M.D.,† has been appointed provisionally to the position of District Health Officer, in charge of the Amsterdam, N. Y., district, comprising Fulton and Montgomery Counties.

ALBERT E. AUSTIN, M.D.,* of Old Greenwich, Conn., former Health Officer of Greenwich, was elected to the House of Representatives as a Congressman in the November election.

DR. MARTHA WILSON MACDONALD, formerly in charge of the Children's Division of the Department of Psychiatry at Michael Reese Hospital, Chicago, Ill., has been appointed Director of a new child guidance clinic in New Orleans.

HELEN C. MANZER, PH.D.,† formerly Director of Nursing Education, New York University, is now Associate Professor of Education at the University.

HALSEY J. BALL, M.D.,* Health Officer of the Utica District, including Herkimer, Madison, and Oneida Counties, has retired from active service. He was associated with public health work from 1892.

HAROLD J. CONN, PH.D., Chief of the Department of Research in Soil Bacteriology in the New York Agricultural Experiment Station at Geneva, N. Y., has taken up special work at the Scripps Institution at the University of California, Berkeley, Calif., where he will study the growth of the soil bacteria in synthetic or prepared soils.

GORDON R. GRAY, M.D., C.P.H.,† of Amsterdam, N. Y., Assistant District Health Officer, is now in charge of the Batavia, New York, sub-district with jurisdiction over Orleans, Genesee, and Wyoming Counties.

RICHARD P. STRONG, M.D., for 25 years Professor and head of the Department of Tropical Medicine, Harvard Medical School, Boston, Mass., has retired from active teaching and has become Professor Emeritus.

Southern States

IRVIN ABELL, M.D., of Louisville, Ky., President of the American Medical Association, received, in a ceremony on November 5, the Laetare Medal of the University of Notre Dame, Notre Dame, Ind., awarded annually to an outstanding Catholic layman.

STEPHEN J. BEEKEN, M.D., for some months Assistant Health Officer for the Rockbridge County, Va., Health District, has been appointed Health Officer of the Russell-Tazewell Health District, with headquarters at Richlands.

DR. WILLARD W. GRIGGS has been appointed Health Officer of the Dicken-

* Fellow A.P.H.A.

† Member A.P.H.A.

son-Wise Health District, with headquarters at Norton, Va.

CLARENCE PORTER JONES, JR., M.D., has been appointed Assistant to ROBERT P. COOKE, M.D.,† of the Rockbridge County Health Department, Lexington, Va.

DR. GEORGE BOYCE LYNCH, of Brevard, N. C., has been appointed Health Officer of Transylvania County.

JOHN G. McNIEL, M.D., has been appointed Health Officer of the Montgomery County, Va., Health District, with headquarters at Christiansburg, Va. He succeeds WILLIAM M. FULLER, M.D.,† who is enrolled at the Johns Hopkins School of Hygiene and Public Health, Baltimore, Md.

ELLIS S. TISDALE, S.B.,† of Charleston, W. Va., for 22 years Sanitary Engineer in the West Virginia State Department of Health, has been granted an indefinite leave of absence to accept an appointment with the U. S. Public Health Service in connection with the stream pollution study of the Ohio River Basin. J. B. HARRINGTON, for several years Assistant Sanitary Engineer in West Virginia, has been named to succeed Mr. Tisdale as Director of the Sanitary Engineering Division.

HUNTINGTON WILLIAMS, M.D.,* has been reappointed Commissioner of Health of Baltimore, Md., for a term of 7 years.

L. L. WILLIAMS, M.D.,† Senior Surgeon, Malaria Investigations, U. S. Public Health Service, Washington, D. C., gave lectures on malaria at the University of North Carolina, Chapel Hill, N. C., October 31 and November 1.

MARK V. ZIEGLER, M.D.,† Senior Surgeon and Regional Consultant, U. S. Public Health Service, Washington, D. C., gave a lecture and showed a film on the work of the U. S. Public Health Service at the University of

North Carolina, Chapel Hill, N. C., November 8.

Western States

CHARLES L. COYLE, M.D.,† of Marshfield, Ore., has been appointed Health Officer of Coos County.

DR. FREDERICK SYDNEY HANSEN,† formerly of Pendleton, Ore., has been appointed Health Officer of Multnomah County.

ALFRED H. MACLAREN, M.D.,† formerly of Portland, Ore., has been appointed Health Officer of Umatilla County.

DR. PETER H. ROZENDAL † formerly of Lake Preston, S. D., has been appointed Health Officer of Klamath County, Ore.

Ecuador

HENRY HANSON, M.D.,* of Guayaquil, Ecuador, on the staff of the Pan American Sanitary Bureau, was recently decorated by the Ecuador Government with the Order of Merit, recognizing his services in connection with bubonic plague. Dr. Hanson was formerly State Health Officer of Florida.

DEATH

ELLA PHILLIPS CRANDALL, of New York, N. Y., died October 25. Miss Crandall became an instructor in public health nursing at Teachers College in 1910, and 2 years later, when the National Organization for Public Health Nursing was formed, became its first Executive Secretary. In 1920 she resigned from the N.O.P.H.N. and in 1921 became Director of a special committee to study community organization for health protection as worked out under the Association for Improving the Conditions of the Poor in New York City. At the time of her death Miss Crandall was Director of the Payne Fund, of New York.
